A CASE OF
OSTEO-MYELITIS OF THE TIBIA,
SIMULATING ACUTE RHEUMATISM.

By WILLIAM MURRELL, M.D., F.R.C.P.,
Physician to the Westminster Hospital, Lecturer on Clinical Medicine and Joint Lecturer on the Principles and Practice of Medicine in the Westminster Hospital Medical School.

In a recent paper (a) I mentioned osteo-myelitis as a disease which might be mistaken for acute rheumatism. The following is a case in point:—

A carman, 27 years old, was sent to the Westminster Hospital on December 5th, 1900, with the diagnosis of acute rheumatism. He stated that two days previously he had been driving a van in the pouring rain, and that on reaching home he had suffered from pains in the joints. The pain gradually settled in the left knee, and finding that he was unable to work he sought admission. He had never had rheumatic fever, scarlet fever, gonorrhoea or syphilis, and there was no complaint of sore throat. There was no family history of importance.

On admission, the temperature at noon was 101.8°, and at 4 p.m. 104.2°; at 8 p.m. 105°. He was sponged, and the temperature fell to 104.4°. There was some tenderness in the shoulders and wrists, but the inflammation was confmed almost entirely to the right knee, which was red, swollen and tender. The urine contained a trace of albumin, but no sugar. There was no abnormal sweating, and there were no rigors. The urethra was squeezed, but there was no discharge. On the 6th the lowest temperature was 102.8° and the highest 104°, whilst on the 7th it ranged from 100.8° to 103.6°. On the 8th it was found that the pain and tenderness were not confined to the knee, but extended half-way down the tibia. Pericardial friction over a limited area was detected, both on palpation and auscultation, but there was no effusion. On the 9th the patient had low, muttering delirium, a brown, furred tongue and indications of septic anemia. The temperature at noon was 102.6°, pulse 120, respiration 30. The following report was received from the clinical laboratory:—The plasma is very yellow, and the red corpuscles take more readily than natural. Red blood corpuscles, 4,900,000 per cm., leucocytes 12,800. Finely granular oxyphiles 70 per cent., coarsely 2 per cent., hyaline 20 per cent., lymphocytes 8 per cent.

The organisms present in the blood were staphylococci.

No other lesion except the acute swelling over the upper end of the right tibia on its inner aspect could be detected. An incision was made over the inner tuberosity of the right tibia and a small quantity of thick pus under the periosteum evacuated. There were little pockets of pus in the subcutaneous tissue. The diaphysis of the tibia, which was bare and soft, was bored into until the cancellous tissue was reached, and a little pus escaped when the cavity of the tibia was scraped out. After the operation the temperature was 101.8°, pulse 120, and respirations 32. The patient passed a restless night and the delirium continued. There was profound anæmia with slight jaundice, the tongue was dry, the pulse 124, rapid, running and irregular. Antistaphyloccocic serum was injected without benefit. Later in the day Mr. Walter Spencer amputated through the lower third of the tibia. A culture from the medullary canal of the amputated limb showed staphylococcus aureus. The patient died on the following day, and at the autopsy the periartium was found to be roughened, and there was turbid fluid in the sac. The lungs showed extensive broncho-pneumonia, breaking down in many places into abscesses. The right pleura was covered with the semi-purulent fibrin. The kidneys showed many yellow, purulent foci scattered throughout the substance.

Cases of acute osteo-myelitis, although they usually come under the care of the surgeon, are of especial interest to the physician from their liability in the early stage to be mistaken for acute rheumatism. The greater intensity of the local symptoms, the involvement of the epiphyses rather than the joints, and the more serious constitutional disturbance are usually sufficiently diagnostic. In this case, on admission, the characteristic signs of osteo-myelitis were absent. The patient was a young man of an age at which acute rheumatism is common. There was a distinct history of exposure to cold and wet, and apparently several of the larger and middle-sized joints were involved. The temperature for the first few days was not unusually high, and there was nothing in the aspect of the patient to excite suspicion. Even when the pain was apparently confined to one joint there was nothing to show that it was not the joint itself, but the neighbouring structures that were involved. There was no swelling, it was true, but there are many cases of acute rheumatism in which this is not a prominent symptom. Possibly an earlier blood-count might have excited suspicion, but this is doubtful, for the value of

next day erysipelas set in, which carried him off in four days.

My second patient was a lady, aged 72. Called to her, I found that she had been taken with right hemiplegia and facial paralysis, and a few days afterwards she succumbed to an attack of apoplectic ictus. The history of her case is as follows:—One morning the patient, who generally slept well, awoke after a bad night, disturbed with nightmare; she complained of a sense of heaviness in the head, vertigo and foggy vision. A few minutes after the nose began to bleed alarmingly, she fainted, and the blood came down her face. The patient is not often pinching of the nose, elevating the arms, cold water, &c., were first employed, and with temporary success; the bleeding ceased at noon, returned slightly at two o’clock, and finally at five. Then happened what so frequently is observed in similar circumstances when night is approaching near the patient, and there got frighted, and sent in haste for a doctor. At six o’clock a young practitioner was called in, and, entreated by the patient and the persons present, who showed him the basin half filled with blood, he proceeded to pass a soft catheter through the nose, and plugged the anterior and posterior orifices. He operated with dexterity and with great precaution to the patient, and took his departure, leaving everyone satisfied and tranquil in mind. He returned the next day, found matters going on well, and did not disturb the plugs. Nevertheless, different signs ought to have awakened his attention. The patient had been constipated for two or three days, and the blood had been considerably below the norm. Called for epistaxis, he thought only of the one object, and was contented with his success. The following day, however, apoplectic ictus set in, and the patient succumbed two days afterwards.

I did not relate you this history simply to interest you in a pathological drama; it is one example near the patient, and these about a man who told me some time ago that when he was house surgeon at the Salpêtrière, he had frequently been called to plug for epistaxis in aged persons. One day Cazalis, in whose ward he was, asked him if he had ever occurred to him to inquire what had become of those he had plugged. The idea was new to my friend, and he made some inquiries. To his great astonishment, he found that several of those patients had died one or two days after he had treated them, and the autopsy revealed cerebral hemorrhage.

Nasal hemorrhage opening the vessels of the pituitary lowers the threatening arterial hypertension, relieving frequently those vessels of quite other disease of the brain. Consequently, when you are put in presence of an epistaxis, endeavour to remain calm, although solicited on all sides, and do not commit the fault of operating without having sufficiently examined your patient.

There exist for moderate epistaxis a number of simple means that can be tried in the first instance; they will not always stop the hemorrhage completely, but therein lies frequently the safety of the patient. Never begin your treatment in any case by plugging the anterior and posterior orifices. In young persons with healthy arteries you might follow this treatment, no doubt, almost without hesitation, but in aged persons do not forget that this operation is a treatment of necessity and never of choice. Primum non nocere is the old adage, and I wish you to bear in mind two things: plugging the nasal fossae in aged persons is dangerous, and perchloride of iron should never be used.

There are persons who, in addition to the above, prescription a quantity of innocent methods: elevation of the arms, application of cold water, keys down the back, which produce a reflex spasm. These means succeed sometimes. After you may try small plugs steeped in a solution of antipyrine, oxygen water, irrigations with hot water; they will be sufficient to at least moderate the hemorrhage, if not arresting it completely; it is better in any case that the vessels open in the pituitary membrane than in the brain.

To resume, resist the first movement to institute a symptomatic medication without having studied the general condition of the patient. Try dry cupping in the lumbar region, purgatives, mustard foot baths, applications of hot water to the abdomen, and only resort to plugging when you cannot do otherwise.

ANTI-TUBERCULOUS DISPENSARIES:

AN ACCOUNT OF THE WORK DONE, PREVENTIVE AND CURATIVE, BY ANTI-TUBERCULAR DISPENSARIES. (a)

By Dr. LEON BONNET,

Of Paris.

The first of the anti-tuberculous hospitals or dispensaries opened under this name was that of Dr. Léon Bonnet, in January, 1900, at 28, rue St. Lazare, in Paris. They are intended to bring to thousands of the poor gratuitous use of scientific and new methods of treatment of diseases, especially of those which are contagious, avoidable, and curable, notably pulmonary tuberculosis. In the month of April, 1900, the Echo du Public and the Revue des Découvertes modernes, et de leurs Applications aux Sciences médicales, published accounts of their foundation under the presidency of Dr. Bonnet. In the month of July of the same year Dr. Malvoz, of Liège, installed in his laboratory a similar dispensary. The year following, in the month of February, Dr. Guimette organised in the hall of the Pasteur Institute, of Lille, a dispensary for indigent tuberculous patients, under the name of "Dispensary for the Cure of Lung Diseases." He also proposed a commission for the consideration of the best means for combating the evil. The anti-tuberculous dispensary was removed from the rue St. Lazare to 115, rue Marcadet, Montmartre, in the beginning of the year 1901, when it was formally opened by Professor Brouardel on its completion on May 6th, 1901. The dispensary Emile-Roux, of Lille, was not opened until December, 1901. Immediately after the Congress in London—which approved of the idea of the anti-tuberculosis dispensary—at the instance of the President and the Mayor of Montmartre, and through the influence of M. Waldeck-Rousseau, at that time President of the Ministry at the First Assembly, also of the promoters of the anti-tuberculous dispensaries, the great work was initiated in Paris, in France, and abroad in support of the creation of these dispensaries, education concerning, and relief from, tuberculosis disease—the disease of ignorance and...
miser. The cities of Nantes, Nancy, Reims, Dijon, Limoges, Roubaix and others sent their approval of and adherence to the scheme of the committee of management, who soon afterwards opened seven new dispensaries, one each at Vaugirard, Grenelle, Plaisance, or Gobellins, Ménilmontant, Buttes-Chaumont and at Batignolles respectively, the unhealthiest districts in Paris. The most distinguished members of the medical profession, scientists, politicians, literary men, including such as MM. Berthelot, Boucheo and Dupuy, Dupuy-Danican, Ducos, Guyon, Hébrard, Roussel; MM. Charles Dupuy, Etienne, Flourens, Guillaumin, Ribot, Seigfried, ex-Ministers; MM. Paul Deschanel, Laredan, Sully-Prudhomme, of the French Academy; came forward to assist the work. The Consul-General of the Seine and the Municipal Consul of Paris publicly declared their approval. MM. Etienne, Vice-President of the Chamber of Deputies, Alexandre Bérard, Under-Secretary of State, Chaumié, Minister of Public Instruction, came forward some months after with their support, when M. Waldeck-Rousseau had visited and inaugurated the new establishments. Conferences were held between MM. Mille, Mme. of the Council of State, Laborde, of the Academy of Medicine, at which they formulated an excellent scheme for the struggle with tuberculous disease. The principle announced was the education and assistance of the poor threatened with or already suffering from tuberculous disease. The medical superintendent is entrusted with the establishment of an educational and sanitary service. He takes cognizance of their efficient working as an educational centre, a prevention of disease station, a curative dispensary, but also as an instruction, course and supply station. He plays no unimportant part in the war against this modern plague. The committee of management has decided against building except where absolutely necessary, and have decided on erecting isolated pavilions surrounded by gardens. The anti-tuberculous dispensaries formed on the type of the Paris ones contain a room for registration of patients, one for the distribution of food and medicine, a dressing room, a consultation room, and a large mycological examination and for radiography; also a laboratory, a special ward for cases of advanced phthisis, and, lastly, a great hall in which respiratory gymnastics are practised daily in a specially purified atmosphere. Besides these, there is a lecture hall, a day room, and a lounge. The primary intention of these dispensaries is the provision of medicinal and dietetic treatment, and should be situated in its early stages, when it is practically non-contagious and curable. The hours for gratuitous consultation are from 7 p.m. to 10 p.m., a time most convenient for the poor who are engaged during the day. After a consultation with the physician, the patient, with his fellows, rest themselves in a hall of the most gratifying character, for it is thought that by a change of air and moral standpoint. When the dispensary is in the vicinity of a large railway station, many come from the suburbs which are not yet provided with dispensaries, and carry back with them the principles of hygiene, and particularly those bearing on tuberculous disease. The anti-tuberculous dispensary is intended to carry out two parallel functions: the lessening of the risk of contagion and the improving of the chance of cure. Most interesting results have been obtained
by the systematic employment of raw horse flesh as a food. The value of this meat was first recognised by Fürster, in 1865, who recommended it as the most efficient medication; indeed, he considered it almost as a specific for tuberculous disease if taken in sufficient amount, from 750 grammes to 1 kilog. each day. After three years Dr. Leon Fontet, in the dispensary of the Rue St. Lazare and in the other dispensaries, decided on the adoption of the raw flesh of the horse as a diet most suitable for the tuberculous. It appears that this flesh is more wholesome than that of oxen or sheep, more nutritious and richer in minerals, and when eaten raw the great advantage it has over other meat is that the patient incurs no risk of tertia. The statistics published at the end of the first year of its use in the dispensary of Montmartre, by Dr. Madeleine, chief of the clinic, shows that this food is nourishing and enables the body to resist the tubercle bacillus. It was found that after some weeks' feeding on the uncooked food a general improvement was at first noticeable; the orthoscopic signs evidenced arrest of the disease, the appetite improved, the weight increased, and the strength increased. Finally, the poor workman came in time to recognise the truth of the teaching in the dispensaries, and its effects were demonstrable in the habitations and food he selected. The committee of the dispensaries put forward the opinion that physicians in every country should make a trial in cases of tubercle of the lung—the disease of the unfortunate poor—of raw or macerated horse or mule flesh in large amount.

[Geoffrey Saint-Hilaire, in 1866, published his lectures on the value of horse flesh as a food, and two years afterwards Munaret (1858) published a pamphlet on the same subject. The earliest of the modern writers on the subject is, we think, Kreutzer, 1847.——TRANSLATOR.]

France.

FROM OUR OWN CORRESPONDENT.

PARIS, June 26th, 1903.

CHLORIDE OF SODIUM AND CARDIAC DISEASE.

At the Medical Society, M. Merklen spoke on the retention of chloride of sodium in cardiac oedema, and for that reason advocated the milk régime, that liquid containing but a feeble quantity of chlorides. The rôle of chloride of sodium in dropy was, besides, demonstrated by the large quantity of the salt contained in the oedema liquid. In one case of astylic disease with considerable oedema, which rest and lactic diet rapidly diminished, he found by analysis that the first day of the treatment the patient omitted five quarts of urine and twenty grammes of chlorides, and the following day six quarts and thirty grammes of chloride of sodium. Consequently, there was retention of chlorides in cardiac patients as well as retention of water when the urinary secretion became insufficient by reason of renal stasis or intercurrent nephritis. That retention might be the cause and effect of dropy, which resulted not only from stasis and hypertension in the capillaries, but, above all, from the rupture of the osmotic equilibrium between the blood and the interstitial plasma of the tissues.

Chloride of sodium being the most abundant of the substances dissolved in the blood, and playing a principal rôle in the maintenance of the osmotic equilibrium of the humours, it was that salt which most rapidly would be thrown into the cellular tissue with the water necessary to re-establish the equilibrium between the blood and the lymph. If his idea was correct, it was easy to understand the rôle of alimentary régime, on the appertain, aggravation, persistence, or disappearance of the oedema of cardiac patients, according to whether it is rich or poor in chloride of sodium, and also naturally whether the urinary elimination was or was not sufficient.

M. Achard said that he observed several cases demonstrating the rôle of chloride of sodium in cardiac oedema. He had seen one case, notably, where the malady became aggravated after the ingestion or subcutaneous injection of ten grammes of the salt.

M. Widal came to the same conclusions, but thought that the phenomena were still more marked in acute nephritis. Patients of that class were very sensitive to an excess of chlorides, as the oedema returned and disappeared according to the increase or suppression of chlorides in the diet. He had observed a child with Bright's disease in whom the administration of theo- bromine increased the urinary excretion without diminishing the ascites. Analysis of the urine showed that in spite of the polyuria, the elimination of the chlorides was insufficient.

GERMANY.

FROM OUR OWN CORRESPONDENT.

BERLIN, June 27th, 1903.

At the Society für Innere Medizin, Hr. Heller reported a case of septic endocarditis complicated with gonorrhoea. When we come across a case of endocarditis along with gonorrhoea we are at once inclined to assume it to be a case of gonorrhoeal endocarditis, mixed infection being relegated to the background. The case showed, however, that such did occur. A man, at 47, had had gonorrhoea in his youth, which was followed by a stricture of the urethra. In August last he sought advice for a gonorrhoea, and in the discharges both gonococci and staphylococci were found. At the end of the month there were both urethrocystitis and prostatitis. A sound was not passed as it was feared that the gonococci might, in consequence, find entrance into the blood. Salicylic acid was given. On August 28th a purpura exanthema appeared, in which there were small efflorescences in patches around the dilated vessels, which were joined together by haemorrhage. On the 28th he appeared quite bright, but on the 31st collapsed, and the speaker found all the signs of a left hemiplegia; the lower part of the face was also paralysed and there was complete unconsciousness. Endocarditis had therefore developed, giving rise to embolism and secondary haemorrhage into the vein. Death took place in a few days. An autopsy could not be obtained, but a portion of the skin efflorescence was taken for examination. They were especially found at the extremities and under the nails. The efflorescence was seen to be caused by capillary embolism. These lay in aggregations, were not intracellular, and were stainable by Gram's method, and did not contain gonococci; a pyemic dermatitis had developed along with a gonorrhoea. The invasion by the staphylococci had been rendered possible by the softening of the mucous membrane by the gonococci. He only related the case to show that not all cases of endocarditis in gonorrhoeal cases were themselves gonorrhoeal.

Hr. v. Lyden remarked that the absence of joint symptoms pointed to a non-gonorrhoeal cause for the endocarditis.
At the Surgical Congress Hr. Kraske, Freiburg, spoke on

TRENDELENBURG'S POSITION AND ITS DANGERS.

Everyone, he said, recognised the advantages of the position introduced by Trendelenburg. He had employed it many times and could no longer dispense with the advantages afforded by it. He would not discredit it, therefore, when he mentioned certain disadvantages and dangers that might, under certain circumstances, be brought about by it. He would, on the contrary, increase its value by rendering clear the circumstances under which danger might arise, when it might be dispensed with, or, at any rate, the needful precautions that might be taken. Individual communications had appeared concerning injury sustained by the use of the position, as, for instance, paralysis of the peroneal nerve, and emphysema of connective tissue of the abdominal parietes. In the latter case it was assumed that more air entered the abdominal cavity, and it was forced into the connective tissue by vomiting. Neither of the cases need be considered, as they were not of importance and could easily be avoided. The changes in the circulation associated with the position were of more importance. He could not free himself from the anxiety that this circulation might set up disturbances in the heart and lungs. Two experiences in this. They were the same man, aged 40, and one, aged 50, in whom the high operation had been performed, one for calculus and one for recurrent papillary growth in the bladder. Both patients had cardiac disturbance from endocarditis, the cause of which was considered to be the severe cystitis. In both the operation was free from difficulty, but immediately after the operation the cardiac condition became suddenly worse. Both patients died, one on the second, the other on the fifth day after the operation. Ether was the anaesthetic employed. He thought the result was due to acute dilatation of the cardiac walls brought about by the position. He had had two further experiences. He did the high operation in a healthy, but corpulent man. The operation was easy and occupied only twenty-five minutes. After the operation the patient seemed quite well, with no vomiting after the anaesthetic, but the next day he complained of fulness of the abdomen, and no flatus passed. There was tenderness over the parts, but no fever. The next three days the symptoms got worse, and he felt certain there was some hindrance to the bowel function. He thought of operation, when a sudden change took place. A considerable quantity of flatus was passed, then a stool, and the patient recovered. A second almost similar case occurred this year, but in the vomit blood appeared, and, later on, pure blood. The abdomen was not tender, the pulse was accelerated. An abdominal incision was made. The whole omentum was glued into a great lump and lay below the liver, and the transverse colon was twisted on its axis. Things were straightened out and flatus and faeces passed before the dressing was completed. The patient died, however, soon after the operation. The mechanism of the case he explained as follows:—Through the high pelvic position the heavy omentum found its way under the liver and caused tension of the transverse colon. In the horizontal position the omentum was retained in position. Schauta had observed a similar case of tension under the high pelvic position. From these occurrences he drew the teaching that after the high pelvic position, the patient should be brought back to the horizontal one, and the operator should satisfy himself that the omentum and intestines were right before the abdominal wound was closed.

AUSTRIA.

[FROM OUR OWN CORRESPONDENT.]

LEPROX MIXTA.

NEUMANN showed a man at the Gesellschaft, aged 41, who had been brought to him from Sofia with leprox mixta. On both hands were red-brown infiltrations about the size of beans, which had partially broken down. The lower extremities were affected in a similar manner, and around the affected parts the sensibility was partially lost, as well as the temperature sensation. Both nervi brachiales were greatly thickened. The patient had never during his lifetime been out of Bulgaria, so that the case may be designated autochthonic, or produced in the country where it is not epidemic.

CYSTOTOMY.

Oesterreicher brought forward a man, aged 30, on whom he had operated for stone in the bladder by performing perineal cystotomy, as he calls it, according to Frank's method. He contends that this is the best method for removing calculi, as it affords better drainage, the less risk to the patient, who recovers within eight or ten days after the operation.

HERNIA AND PARAFFIN INJECTIONS.

Escherich exhibited several children on whom he had operated for hernia by the injection of paraffin. After replacing the protruding bowel he injected 1 to 5 c.c. of paraffin, whose melting point was 38°C., or 92.4°F., into the sac by means of a curved needle on the syringe. Immediately after the paraffin is injected ice is applied to harden the fluid paraffin in the sac, which at once forms a firm barrier against further protrusion of the bowel with the assistance of a strip of plaster. Weil thought there was some objection to be raised against the ice application, and had used methyl chloride for this purpose with perfect success.

MAXILLARY CYSTS AND IODOFORM.

Ernst demonstrated from two cases which he brought forward the great advantages to be obtained by plugging the cavity with Mosteg's iodoform mixture, with which he has had the best results.

Chiari said that this method was rationally the best that could be adopted for chronic cerebral and maxillary cavities.

Weiser thought the dentist obtained equally good results from Partisch's method of removing a part of the cyst wall and allowing the cystic epithelium to be brought into close contact with the mouth, thus inducing shrinking and final closure of the cavity. Weiser asked if Mosteg's bone-plugging mass could be injected through a narrow bony fistula in sufficient quantity to fill a large cyst following an alveolar abscess.

Mosteg replied by saying that the abscess would require previous preparation by washing, cleansing, &c., before finally closing with the stopping mass. He had now practised this method in 150 cases, with the best results. He related two cases of tuberculous origin which he had treated with the stopping material with the utmost satisfaction, as the post-mortem in subsequent proved the results to be perfect. After death the abscesses were to be healed, while in the posterior mediastinum and parts of the sternal bones the cheesy, scrofulous matter could be scooped out. In connection with the pleura and pericardium, a mass of tuberculous matter weighing 200 grammes was removed. After this experience he had since applied the treatment in two other females of a similar nature by injecting the mass into these tuberculous sacs in the chest and
sternum, and found that after fourteen days the fever suddenly subsided and the patient became well.

Ernst thought that Parcs's method had serious objections, as food got into the cavity and decomposed, leading often to fatal results.

Continental Notes.

[FROM OUR OWN CORRESPONDENT.]

EMS.

At this time, when so many new mineral-water resorts are being vigorously pushed forward, it is perhaps well to halt a little "at the parting of the roads" to see if there is any cause why the older spas should be cast aside for newer places. Among the older Continental health stations, Ems has many claims to favourable remembrance for "auld acquaintance" sake. Its hotels are excellent, and have long been adapted to our British prejudices and preferences. Among them is that old English house the "Hôtel Angletterre," in a choice position, immediately opposite the Royal Baths and near the Grand establishment. Also another popular hotel, "Four Seasons and Europe," having not only direct covered communication with the Royal Springs and drinking arcades, but its own thermal saline springs, baths, and indoor inhalation institution. There are a variety of other good hotels and pensions—the "Continental," "Roemerbad-Kurhaus," "Königliches Kurhaus," "Four Towers," "Darmstadenhof," "Schloss Balmoral," "Métropole," "Russe," "London," "Bristol," &c., &c., giving visitors an abundant choice in their selection of a domicile during their stay at Ems.

Agreeably located on the Lahn, with wooded hills on three sides sheltering it from cold winds, and enjoying a drier climate than many other spas, Ems offers a pleasant kingdom for the indolent and the rest-seeker apart from its waters. Here is a summer theatre, concerts thrice daily by a talented German philharmonic orchestra, casino and reading salons, balls, boat races, tennis and croquet matches, hunting and, what is seldom found abroad at fashionable resorts, good fishing. Pike, roach, chub, &c., abound in the river Lahn, which is found in places within an hour's drive, and at St. Goarshausen on the Rhine are salmon.

Ems is well situated for excursions to the Rhine and Moselle valleys; while that of the Lahn, is in itself, particularly in its upper reaches, rich in lovely nooks and corners. A mountain railway runs up to the Hohenwalberg climatic resort.

The Ems mineral waters have long held high rank for the treatment of asthma and lung difficulties, catarrhal affections of many kinds (nose, throat, larynx, windpipe, stomach, intestines), gout, rheumatism, feminine disorders, nervous diseases, &c. The season is from April to October, May, June and September being the chief "English" months.

BRITISH SANATORIA FOR CONSUMPTION.—I.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

Pessimism in regard to the arrest of pulmonary tuberculosis has passed, and ignorance as to the most effective means for securing the arrest of the disease is passing. For a long time pioneers have taught the necessity for a rational application of natural agencies in the treatment of consumption; but it is only within the last few years that the brilliant results which have followed the systematic employment of so-called "open-air" methods have convinced the profession of the scientific value of hygienic treatment and converted the public to an enthusiastic adoption of a course almost entirely at variance with that hitherto generally followed.

The upspringing of sanatoria for consumption in all civilised countries affords ample evidence of the firm belief in the efficacy of a hygienic life in arresting the morbid processes underlying pulmonary tuberculosis. The general principles of the hygienic treatment of consumption are now more or less clearly recognised, but there exists very wide diversity of opinion and divergence in practice as to the manner in which such may be best applied to secure most speedily and effectually the restoration of the tuberculous individual.

It is now generally admitted that institutional treatment affords the most trustworthy means for securing those conditions of environment and developing those states of tissue activity which are essential for arrest of the disease and necessary for the uplifting of the protective powers of natural cell resistance to invasion by the tubercle bacillus.

Sanatoria undoubtedly offer the most efficient and effectual means at present available for combating what has up to comparatively recent years been considered an almost hopeless afflication. And such establishments not only offer facilities for a segregation which uncontrolled may prove detrimental to those living in association with them, but provide at the same time ample opportunities for securing physiological conditions making for natural arrest, and a sound education as to those details which are all-important if relapse is to be avoided and a useful life maintained. The essential elements in the hygienic treatment of consumption are constant exposure to fresh air, free access to sunlight, regulated rest and controlled exercise, abundant and good feeding, compliance with all hygienic requirements, and effective nursing with a constant and strict medical supervision.

It is only by a rigorous and disciplined conduct of such measures that the tuberculous patient can be protected from fresh invasion by the tubercle bacillus, establish processes of repair and develop vigorous powers of tissue resistance.

All sorts and conditions of so-called sanatoria are rapidly springing up in this country, and much difficulty is being experienced by practitioners in obtaining trustworthy and unprejudiced particulars concerning the various agencies or ascertaining the results obtained by those of the different sanatoria now professing to provide efficient treatment for the consumptive.

It must be admitted that to some extent sanatorium treatment is still open to the criticism, the limitation of time is to say, while there is no doubt as to the general advantage of open-air methods over previous procedures, there is wide difference of opinion and practice, not only regarding the construction and management of sanatoria, but also in the manner of the application of various details of the hygienic life.

In some respects this variation in conduct and procedure is to be regretted, but, rightly viewed, it is seen to be an unavoidable and, indeed, necessary feature in the establishment of a new system of treatment. It is, however, very necessary that every sanatorium should be conducted on rational lines, directed by scientific principles, and all freely open to inspection. It is also much to be desired that means should be found, even though it might necessitate the establishment of another society, whereby those responsible for the management of sanatoria, and those engaged in clinical investigation and scientific research at such institutions, should have more ample opportunities for comparison of methods and co-operation in accurate study. At present, in only too many instances from the lack of adequate scientific combination, much time and energy is being lost and good work dissipated.

In order to provide trustworthy information for the practitioner and encourage a more effective combination among those scientific workers engaged in sanatorium practice, the Editors of The Medical Press and Circular have arranged for a special series of articles...
The Operating Theatres.

KING’S COLLEGE HOSPITAL.

Operation for a Strangulated Femoral Hernia Reduced en Masse.—Mr. Peyton Beale operated on a case exhibiting the following symptoms:—A woman, aged about 60, had been admitted complaining of colicky pains in the abdomen and vomiting for three days. The patient had been under Mr. Beale’s care in the out-patient department with a double inguinal hernia, for which she had been provided with a very efficient truss. The patient’s abdomen was very carefully examined and appeared quite normal when under the influence of an anesthetic; the inguinal, obturator and femoral regions were also examined, but no hernia could be detected. As the fecal vomiting still persisted, the abdomen was opened in the middle line. On introducing the hand and exploring the cavity, nothing abnormal was found until the hand reached the left side of the pelvis; here there was a solid-feeling, globular mass as large as a cricket-ball, in the situation of the femoral ring and projecting into the pelvis; the intestine could be felt passing into it, and on further examination two pieces of intestine were discovered. Gentle traction was made on these, and after a few minutes a loop of intestine was withdrawn and exposed to view through the abdominal wound; this was so badly strangulated in two situations that it was left outside the abdomen, the remainder of the abdominal wall being closed. Mr. Beale said that he believed the case to be one of strangulated femoral hernia which had been reduced en masse, but there was no history of a femoral hernia or of its reduction to be obtained from the patient, who was suffering from bronchitis and emphysema, and was in an extremely bad condition to undergo operation.

GREAT NORTHERN HOSPITAL.

Laminectomy.—Mr. Peyton Beale operated on a woman, aged about 60, who had been admitted into the medical ward with the following history:—About four years ago she experienced an aching pain over the fourth and sixth dorsal spines; the pain was described as of a gnawing character and came on chiefly at night. After some months it shifted its position to the region of the left scapula, and had been present in the two situations on and off until the present time. About six months ago the patient noticed a sensation of weakness in both legs, which soon developed into definite pain of the nature of cramp and also of a stabbing character; these pains had been steadily getting worse up to the present time. About three months ago similar pain, together with tingling sensations and girdle pain, occurred in the abdomen and back generally, and with this there was very marked impairment of function in all muscles of the trunk and lower limbs. The patient’s family history was briefly that several near relatives were mentally deficient, one being insane, and others, including one of the patient’s daughters, were very markedly hysterical. The case had been generally considered to be one of hysteria, and had been treated on this assumption. Condition on admission:—There was great impairment of vitality of the whole surface below the area supplied by the third dorsal nerves, but the woman complained of frequent burning and tingling sensations in different positions, and at different times. As regards the muscles, they reacted well, but slowly, to the faradic current and were all well developed, exhibiting no sign of degeneration; ankle-clonus was present, but not continuously. Incontinence of urine occurred for several days at a time and then passed off. The patient appeared to be in an hysterical condition, but at the same time there was obvious impairment in the action of all the muscles below the neck. All usual treatments, including large doses of iodides, counter-irritation to the spine, &c., had been adopted. At this time Dr. Beevor was asked to see the case, and he gave it as his opinion that there was some source of irritation to the cord, together with probable pressure at the level of the fourth dorsal, vertebra, and he advised that an operation should be performed without delay. The following operation was therefore carried out:—An incision about five inches in length, with its centre at the fourth dorsal spine, having been made, the muscles attached to the spinous processes were dissected off and held outwards by means of retractors; the spinous process of the fourth dorsal was then cut away, and the lamine of the same vertebra were removed by bone-cutting forceps; there was considerable hemorrhage from the muscles, but this ceased in a few minutes and allowed a good view of the dura mater of the cord; this was of a purplish colour and very elastic to the touch, strongly suggesting that it was distended with fluid. On being punctured with a scalpel, clear fluid spurted out to a height of three inches. This fluid was allowed to escape gradually, and it was estimated that about four ounces came away between this time and the completion of the operation. The dura mater was then opened freely along the middle line, and the spinal cord, normal in appearance, was exposed to view; the pia mater seemed normal, but an good deal of blood oozed up from around the cord, suggesting rupture of congested capillaries, owing to relief of the pressure of the fluid. On passing a probe upwards in the arachnoid space, the tip of a polypoid gelatinous tumour presented itself at the upper end of the incision in the dura mater; this was pulled down with a pair of sinus forceps, and as it was found impossible to place a ligature round its pedicle it was torn away in pieces and kept for microscopical examination; it had all the appearance of a glioma, and was estimated to be the size of a large pea and seemed to be growing from the arachnoid membrane. The spinal muscles were then sutured, a half-inch drainage-tube, leading down to the incised dura mater, being inserted at the lower angle of the wound; the orifice of the tube was sutured to the skin and the skin edges united elsewhere by a continuous suture; the wound was dressed in the ordinary way.

Remarks on this case will be published in a future number.

Mr. F. R. G. Pakenham, L.D.S., has been elected an Examiner in Dental Surgery and Pathology.

The death is announced of Professor Karl Gusseubauer, Rector of the University of Vienna, at the age of 61. Professor Gusseubauer was a pupil of the late Professor Bilroth, and was himself a bold and successful surgical surgeon. He was the successor of Bilroth in the chair of surgery at Vienna. The cause of death was cardiac disease.
CRIME A MENTAL ABERRATION.

The most casual study of the sad heroes of the causes célèbres which have of late figured in the annals of crime convinces one of the fact that these individuals are physiologically abnormal. The total absence of morality, their indifference to the most elementary principles of right and wrong, and their calmness under circumstances which would, in the ordinary individual, imply extreme mental anguish, constitute so many proofs of abnormality, and of the absence of what psychologists call the moral sense. In the case of Dougal, whose hideous crime has excited and fed the morbid curiosity of the community at large for many weeks past, there is a long and consistent history of criminal instincts culminating in his detention as a criminal lunatic. It is one of the strange features of the trial that no plea of insanity was set up, in spite of this episode in his life history. The physiognomy of the murderer, his restless eyes and his apparent unconsciousness of the gravity of his plight made up a picture with which one is familiar in asylums for the insane. The very heinousness of his crime and the recklessness with which he proceeded to garner the fruit of his deed stamp him as morally irresponsible. If we mention these circumstances it is assuredly not with the object of saving the neck of such a human monster, but merely to emphasise the view which is gradually gaining ground among the thinking portion of the population that crime, at any rate in its more salient aspects, is but the manifestation of latent insanity. In spite of all the efforts of trained judicial minds to formulate a definition of insanity, none has been, or probably ever will be, devised to cover the whole ground. Insanity, considered in its widest application, may be taken to indicate a condition of mind or, if preferred, a cerebral conformation in which the normal equilibrium of the intellectual functions does not obtain. In these unbalanced minds all notions of right and wrong are blurred or absent. Judgment of a sort may be present, but it lacks the necessary elements for its exercise, and the results are proportionately abnormal. The sense of individual responsibility is a very variable quantity, and it varies even in the same individual at different hours of the day and night, and as the result of what he has eaten or drunk. Criminals may be divided roughly into two classes—first, the criminal from birth, one in whom no training can eradicate the criminal instincts which are as normal to him as the sense of duty is to another; and, secondly, the great mass of potential criminals whose moral texture is so loose as to be subject to ephemeral influences of intrinsic or extraneous origin, whether for good or evil. Punishment may be deterrent in respect of the latter; it is useless for the former. The great problem of the future is the prophylaxis and the treatment of crime. Already in respect of inebriety the physician has been invited to step in and assist the magistrate in its repression, thereby implying the recognition of the view long held by physicians that proneness to intemperance is a form of irresponsibility calling for treatment rather than punishment. For the protection of society it may be necessary to place such individuals under restraint, but it is important to our own moral evolution that this should be done, not with the idea of revenge nor even for the sake of the hypothetical deterrent effect of punishment, but merely as a means of protection and possibly of treatment. Our penal code has lost much of its former brutality, and we are beginning to take a wider and more scientific view of the etiology of moral delinquency. We do not make a crime of epilepsy or other diseases of the nervous system, yet in the majority of great criminals the close relationship between unstable mentality and physiological abnormality is very obvious; indeed, Lombroso, the celebrated Italian criminologist, points to unmistakable anatomical features which underlie and explain the functional aberration.

THE LOCAL GOVERNMENT BOARD AND THE POOR-LAW MEDICAL SERVICE.

An important letter appears in the columns of a daily contemporary from the pen of a member of a well-known Irish family, in which the writer directs the attention of the public to the resolutions recently adopted at the meeting of the Irish Medical Association held at Enniskillen. Mr. Walter Kavanagh, the writer of the letter, takes a broad and sensible view of the present position of the Poor-law Medical Service, although, as perhaps was unavoidable in the case of a layman, he falls into a couple of errors. The main points of Mr. Kavanagh's letter may be summarised as follows:—The members of the Irish Medical Association have refused to allow their members to accept a dispensary at a lower salary than £200 per annum, or a workhouse at a lower salary than £150, or the two combined at less than £300. At
present, in consequence of this action, Boards of Guardians are unable to find medical men to fill vacancies, and have to engage temporary officers at salaries varying from £4 4s. to even £10 10s. per week. In the meantime, the Local Government Board refuse to interfere to effect a settlement, and when the Guardians wish to raise a salary will not sanction their action. Mr. Kavanagh considers that the present relation between Boards of Guardians and their officers is impossible, that the life of a medical officer who receives a salary of less than £150 a year is not such as should be forced upon an educated man, that the Irish Medical Association are to blame for issuing a hard and fast demand for a minimum salary, and that the Local Government Board are to blame for not coming forward as arbitrators. It is unnecessary to discuss the position of a medical officer in a wild country district with a small salary and but little private practice. Whatever be the outcome of the present impasse, the days in which Guardians obtained medical men for such districts at the present salaries are gone. There are undoubtedly a few favoured places in which the medical officer with no official salary is better off than his confrère in another district with an official salary of £200 or even of £300 per annum, but such districts are too few to be made into a special class, even if there is any legitimate reason for so doing. It should be clearly laid down that the official salary which is offered to a Poor-law medical officer must not be affected by the prospects of private practice or by any other special circumstances of a district, other than by the amount of Poor-law work to be done. If the private practice of a district is to be taken into consideration at all, it should be as a reason for promotion from one district to another, and the medical officer who did his work best, and who showed ability, should have the prospect of promotion to a better district if he desired to change. The present contention of Poor-law medical officers is that their work is worth a certain minimum salary, and that that salary must be paid if the Poor-law Medical Service is to continue. Mr. Kavanagh falls into an error in considering the action of the Irish Medical Association as unnecessary, and as one that could be avoided by discussion with each Board of Guardians. We fear that no facts, however presented, can have a beneficial effect on the salaries of medical officers, unless they are at the same time accompanied by actions. Why should Guardians on whom rates directly fall be more altruistic than the Local Government Board? A few years ago the then President asked how his Board could shut its eyes to the fact that when a vacancy occurred it was immediately filled, and regretted his inability to interfere. Now, the present head of the Board is compelled to open his eyes to the fact that vacancies cannot be filled, and yet, "as at present advised," he is not prepared to recommend the appointment of a Commission to investigate the working of the Poor-law system. There is nothing to be gained by attempts to transfer the responsibility for the present situation to the medical officers. The Local Government Board must accept that responsibility, or its task-masters, the Treasury. We understand that the Board as a whole is not so opposed to doing justice to the medical officers as its actions would lead one to suppose, but that it really desires to effect reform if the stern controlling hand of the Treasury permitted it to do so. However that may be, someone has to bear the expenses of the present situation, expenses which are rapidly becoming greater than those of a properly-managed service would be. We cannot too strongly re-echo Mr. Kavanagh's hope that the Local Government Board will bestir itself and take up its proper position in such matters—that of guide and arbitrator.

THE PHYSIOLOGICAL STATUS OF THE LARGE INTESTINE.

The large intestine, including the cæcum and the vermiciform appendix, is regarded by some authorities as a superfluous organ in the human organism, one, indeed, which might be discarded to our advantage. It plays no useful part in digestion, and its powers of absorption are insignificant. Experience, indeed, has proved that it may be removed or short-circuited without any appreciable effect on the general health and nutrition. The large intestine is, as a rule, better developed in herbivorous than in flesh-eating animals, a circumstance which is, no doubt, explained by the fact that among the micro-organisms which abound in its contents there are some which secrete a ferment capable of digesting cellulose. It is a noteworthy fact that the large intestine only attains full development in mammals, animals which, for the most part, are of active habits. With most of them rapidity of locomotion is indispensable to the capture of prey and escape from swift-footed enemies; consequently, any delay for the purpose of evacuating the intestines would be inimical to their interests. The large intestine, therefore, serves the purpose of a reservoir akin to the function discharged by the urinary bladder. Birds, which are under no obligation to stop their flight in order to eject the feces, are not provided with a large intestine any more than are reptiles, the amphibia, and other cold-blooded animals which consume a comparatively small quantity of food and are not addicted to active exercise. According to Professor Mechnikoff (a) the large intestine is included in the category of vestigial remains, the persistence of which is fraught with danger to the human organism. In it accumulate the undigested remains of the food which undergo decomposition, with the formation of products very detrimental to the organism if absorbed, as is so often the case in presence of constipation. It is the seat of various serious diseases, more particularly of dysentery, which is the bane of Europeans in the tropics. It is, moreover, the seat of predilection of cancer, nearly 90 per cent. of the cases of intestinal cancer affecting the large intestine. Originally, no doubt, the anatomical arrangement of the alimentary

NOTES ON CURRENT TOPICS.

The Use of Chloroform in the Preparation of Vaccine.

The importance of ensuring the complete sterility of lymph so far as all forms of extraneous bacteria are concerned has now been fully recognised, with the result that accidents leading to the contamination of the supply are very few indeed. So far, the use of glycerine with this object has been attended with success, and is in every way efficacious, though it is not, perhaps, quite so rapid in its action as the manufacturers of lymph would wish. If glycerine be added to lymph in the proper proportion, the extraneous bacteria are eliminated in the course of some weeks, while the specific germ of vaccine remains unaffected. In a recent communication to the Royal Society, Dr. Alan Green brings to notice a new method whereby the same result can be obtained in the space of from one to six hours. This method consists in the addition to the lymph of a saturated solution of chloroform in sterilised water instead of glycerine. By adopting this method, according to Dr. Green, extraneous organisms can be so rapidly eliminated that the vaccine can be distributed for use within a few hours of the time it is taken from the calf, and it also possesses a higher vaccine than does vaccine which has been kept for several weeks. A further report of this process will appear in the report of the medical officer of the Local Government Board for England. The recent outbreaks of small-pox have called attention to the importance of maintaining a proper supply of suitable lymph and to the working of the various institutions which supply it. In a coming number we intend to lay before our readers an account of the preparation of lymph at the Local Government Board Vaccine Institute, near Dublin, which is presided over by Dr. Knox Denham.

The Etiology of Sleeping Sickness.

What is likely to prove a valuable addition to our knowledge of the pathology of the obscure disease of Uganda—sleeping sickness—has been contributed to a contemporary by Dr. Castellani, of Florence. That gentleman, while in Uganda, examined carefully the cerebro-spinal fluid from a case of sleeping sickness, and, in the course of his examination under the microscope, found a living trypanosoma, almost if not quite identical with that found in the blood in trypanosoma fever. He then examined a series of thirty-four cases, and found trypanosomes in twenty, and also found them in the blood in a few cases. Further, in 80 per cent. of those cases in which the trypanosoma was found, at the post-mortem examination he was able to grow from the blood of the heart and the liquid removed from the lateral ventricles a particular variety of streptococcus which he had himself already described on a previous occasion. Influenced by these results, Dr. Castellani makes the feasible suggestion that sleeping sickness is due to the species of trypanosoma which he had found in the cerebro-spinal fluid, and that in the last stages of the disease there is a concomitant streptococcus infection. Considerable support has been lent to Dr. Castellani’s views by the further results obtained by Colonel Bruce, R.A.M.C., who continued Dr. Castellani’s investigations, and who has informed the Royal Society that he has found the trypanosoma in the cerebro-spinal fluid in every one of thirty-eight cases of sleeping sickness which he had examined since the departure of Dr. Castellani, and that he had also found it in the blood in twelve out of thirteen cases. These results promise to furnish an important clue to the etiology of this hitherto puzzling disease.

The Fecundity of the Anglo-Saxon.

Much discussion has recently occurred, especially in American journals, concerning the causes determining the very conspicuous fall in the birth-rate, and the growing evidences of racial decline. Some superficial observers have sought to blame educational systems, but Dr. George J. Engelmann wisely, we think, condemns many of these suggestions as altogether groundless, the chief causes of the low fecundity of many Anglo-Saxons, in his opinion, being their assumption of a false social position, the struggle for the attainment of luxury, and the wilful limitation or prevention of conception. It is well to remember that history repeats itself. Juvenal long since well said: “Few children are born in the gilded bed to the wealthy dame, so many artifices has she, and so many drugs, to render women sterile and destroy life within the womb.” It is certainly necessary that the matter should be faced in a spirit of fairness, and that the spread of “educa-
of Vienna, in a recent review of a series of cases of "pseudo-ileus," treated by hypodermic injections of eserine salicylate, believes that it is a valuable drug for this condition. It has no bad effects upon other organs, and in two instances it appeared to have a life-saving influence. The blood pressure is raised after the injection of one milligramme, so that it acts as a cardiac stimulant. This latter property increases its value, as a certain amount of heart-weakness is often seen, together with post-operative meteorism.

The Use of Rubber Tissue in Surgery.
How to prevent the natural repair of living tissue frequently absorbs as much of the surgeon’s attention as the art of healing up the breaches thereof. The little sinus is mercilessly probed and its orifice enlarged if need be, in spite of Nature’s persistent efforts to shut off all communication with the exterior. The process of granulation is checked or prevented altogether by actual caustics or by the intervention of a foreign substance, such as a strip of gauze. Loss of continuity, a state generally regarded as abnormal, may sometimes prove of greatest benefit, and the less must therefore suffer for the greater. In that most intractable complaint, trigeminal neuralgia, the best results have been obtained by the interruption or interruption of the nerve-channels conducting the painful impulses by resection of the Gasserian ganglion. Dr. Robert Abbe, of New York, believes that this operation may certainly be most successful, but that its beneficial results are seldom permanent. He has therefore tried the effect of interposing a small piece of sterilised rubber tissue between the ganglion and the severed ends of the second and third branches of the nerve involved. The whole operation is therefore subdural, and consequently infinitely safer and preferable. Dr. Abbe has had many patients under his care in whom this operation has been performed, and who have passed the three-year limit without any recurrence of the pain. He accordingly concludes that the complete removal of the ganglion is unnecessary, as by the introduction of the rubber tissue union of the nerve is rendered impossible, and, moreover, the risks from haemorrhage, a not uncommon event in the more severe procedure, are to a great extent obviated. This harmless, non-conducting barrier may prove of service in other painful forms of neuralgia, as, for instance, in sciatica.

Sponge Diver’s Disease.
In certain parts of the world where sponges grow at a moderate depth men specially trained for the purpose dive to the bottom of the seas and tear the sponges from their attachment. In so doing serious injury is sometimes inflicted by an actinium, of the family of actinides, which inhabits the stem, more particularly of sponges growing in the midst of sea-weeds or on mud. The skin of this parasite secretes a viscid substance possessed of virulently irritating properties. When this comes into contact with the human body it gives rise to symptoms the gravity of which varies.
in proportion to the area affected, and the virulence is apparently greatly influenced by the season of the year. Almost immediately the victim experiences intense itching followed by a sensation of burning, starting at the point of contact, but soon spreading over the surface of the body. The neighbouring skin becomes of a dark red hue and ultimately almost black, and later the skin sloughs more or less extensively, leaving a deep suppurating cavity which takes long to heal. Severe constitutional symptoms accompany the local manifestations, and in some cases multiple abscesses form around the seat of infection. One attack does not confer immunity, and so grave are the consequences that of late the employment of naked divers has been to a great extent abandoned in favour of the use of a proper outfit.

Medical Excursion on the Continent.

The fifth voyage d'études médicales, organised by Dr. Carron de la Carrière, is announced to start on September 10th, and it will cover the watering-places of the south-east of France. Starting from Salies-du-Salat, the members will be conducted to Ax-les-Thermes, a charming station at the foot of the Pyrenees, at an elevation of 2,300 feet, to Ussat, Mont Louis (5,000 feet), Amélie-les-Bains, Banyuls-sur-Mer, Montmiraill, and Mont Pilat (3,800 feet). It would be difficult to choose a more interesting and picturesque itinerary, or a more economical and useful way of spending a holiday on the Continent. The cost of the entire trip, inclusive of travelling and hotel expenses from start to finish, is 350 francs (£14), and foreign visitors are accorded a reduction of 50 per cent. on the railway fares from the French frontier to Lyons, whence the start will be made. Professor Landouzy will, as hitherto, take charge of the scientific department, and will briefly describe the attributes and therapeutical indications of the various waters. It is satisfactory to note that the foreign contingent tends to increase in numbers year by year, showing that the exceptional opportunities which these trips afford to become acquainted with the best-known watering-places and health resorts of France are appreciated. Detailed information can be obtained from Dr. Carron de la Carrière, 2, rue Lincoln, Paris, to whom applications to participate therein must be sent at latest by August 25th.

Veterinary Surgeons as Medical Men.

A curious case came before the Court for Crown Cases Reserved in Dublin recently for the purpose of hearing arguments on a case which raised the question as to whether veterinary surgeons are liable to be called upon to serve on juries. A Mr. Charles Allen, a veterinary surgeon, appealed against an order made against him for payment of a fine of £2 for his non-attendance as a juror at the Commission Court in February last. Mr. Allen occupies a high position in his profession, and the case was apparently brought forward as a test one. Mr. Allen’s counsel argued that the petitioner should be exempt from serving on a jury, inasmuch as he came within the description of persons exempted in Section 20 of the Juries Procedure (Ireland) Act, 39 and 40 Victoria, chapter 78, and in the schedule annexed thereto, as being a “licensed medical practitioner”; and further that he should be exempted as a professional man, as the Royal Charter of the Royal College of Veterinary Surgeons dated March, 1844, declared him to be. The Court decided by a majority that Mr. Allen was entitled to exemption. In the report of the proceedings before us, the reason for their decision is not given. We fancy that they can hardly have accepted counsel’s ingenious plea that a veterinary surgeon is a “registered medical practitioner.” It is true that some references were made in the case to the law of juries, as described in Mr. Pickwick, but as judgment was not given in a Pickwickian manner we presume that a decision that a horse is a man was not given. At the risk of being considered “matter of fact,” we should like to point out that the expression “registered medical practitioner” means “any person for the time being registered under the Medical Acts,” and that the expression “Medical Acts” means “the Medical Act, 1858, and any Acts amending the same” passed before the passing of the Act of 1866. At the same time we approve the principle of exempting a veterinary surgeon, who is a veterinary surgeon, from serving on juries.

The Vivisection Debate.

The only satisfactory feature in the debate on vivisection which took place last week in Parliament was the very temperate speech of Sir Michael Foster in defence of the law as it stands. We have nothing but contempt for the members of Parliament who wantonly hurl derogatory epithets at investigators whose only aim in life is to add to the means available for the relief of human suffering and the prolongation of life. Their arguments are so obviously insincere and their logic so faulty that one lacks the patience to refute the venerable libels of which they so complacently make themselves the mouthpieces. These debaters swallow the camel and strain at the gnat. They lie low when it is a question of prohibiting certain legalised forms of cruelty to animals. They utter no shrill cry when Bill Sikes drowns his superfluous puppies; but as soon as an investigator of light and learning seeks to elucidate a moot point in the phenomena of death by drowning by the sacrifice of a casual mongrel they rend the skies with their foolish clamour. They ignorantly or wilfully overlook the great fact that Nature, sooner or later, kills off these self-same animals by injury or disease without regard to their feelings, so that the vivisectionist, after all, merely forestalls Nature’s inevitable climax. The allegation that such men are moved by sheer pleasure in inflicting pain is simply revolting, and is an insult to the intelligence of the public. Fortunately, in Sir Michael Foster and Sir Walter Foster we possess members of Parliament equal to the task of reducing the allegations to their proper position, but such debates are calculated to discourage the earnest seeker after truth.
"Truth" and the Drouet Institute.

Our contemporary Truth continues to demonstrate to the reading world the miserable imposition of the pretended care for deafness exploited by this notorious concern. To borrow a French saying, it is like whipping a dead donkey to point out the absurdity and disingenuousness of the pretensions advanced by those who run this business on the most unscrupulous business principles. Yet our contemporary is doing good service because, even at the present time, when most respectable journals refuse their advertisements, the institute continues to inveigle a large number of persons afflicted with hardness of hearing. We fear the success of ear-quacks is largely due to the fact that the majority of cases of deafness are not amenable to medical or surgical treatment, not that this infers any reproach to aural practitioners, but the fact remains that the anatomical conditions, as a rule, are such as to preclude useful intervention. Consequently, every dishonest quack who will claim to effect what the honest practitioner admits to be impossible is sure of a harvest of sufferers, hopespringing eternal in the human breast. The regrettable feature is that so disreputable respectable journals continue to lend the aid of their advertisement columns to a concern which has over and over again been shown to be a delusion and a snare, and so long as they are willing to sacrifice their morality the institute will flourish.

Honorary Degrees.

No exception can be taken to the honorary degrees which were conferred last Presentation Day on their Royal Highnesses the Prince and Princess of Wales, Lord Kelvin and Lord Lister. Socially and scientifically more honour was conferred on the University by their acceptance than upon the recipients by their selection. So far all is well, but we cordially echo the desire expressed by the Chancellor that the prerogative of conferring honorary degrees is one to be strictly and parsimoniously exercised in future; in other words, that it is not to be regarded as an annual function. Obviously there is little to fear in this direction from those to whose charge the conduct of this great University has been entrusted; but we have on more than one occasion found it necessary to protest against the too generous distribution of such distinctions by certain Universities, a practice which is calculated to bring them into contempt as marks of intellectual merit.

 Alleged Assault by a House Surgeon.

A curious charge of assault brought against Dr. John Knox, jun., house surgeon of the Birkenhead Borough Hospital, by the father of a youthful patient, was heard last week in the local police court. It appears that the lad, six years of age, was suffering from an abscess of the jaw which required to be syringed, a procedure which was resisted by the patient, and it was asserted that the house surgeon lost his temper and struck the child before handing him back to his parents. The lad bore the marks of contusions on the face which, the evidence went to show, were due to slipping of the gag during the efforts to insert it in the mouth. The evidence of Dr. Pierce, a neighbouring practitioner, was that the contusions appeared to have been caused by a blow, and the Bench adopted his view and inflicted a small fine. The case is a most painful one, and assuredly a medical officer who so far forgets himself as to strike a patient would merit condign punishment. So far as an opinion can be formed from the full report in the Liverpool Mercury—a very trustworthy organ—the evidence was anything but conclusive, and certainly nothing but the most unequivocal evidence would justify a decision fraught with such serious consequences to the accused. We can only hope that the decision was erroneous, but unfortunately no appeal is possible on the question of fact.

Queen's College, Cork, and the Royal University of Ireland.

The Triennial Visitation of the Queen's College, Cork, by Lord Justice Holmes and the Presidents of the Royal Colleges of Physicians and Surgeons enabled the Professors of the College to draw public attention to the extremely creditable manner in which Cork students have passed the examinations of the Royal University of Ireland. It appears that since the foundation of the Royal University 1818 per cent. of the students who have obtained degrees have come from Cork, while 29.5 per cent. of the students who obtained degrees in Cork. In other words, although Cork students formed but one-fifth of the whole number of students, they formed almost a third of those to whom honours were awarded. This is all the more a matter for congratulation when we learn that at the time this report was written not a single one of the clinical examiners of the University were connected with Cork College—a fact that speaks well both for the knowledge possessed by the students and for the impartiality of the examiners. We think that we are right in our recollection that at the last examination the only student who obtained first-class honours at the final examination came from Cork College. We cordially congratulate the Professors of the College on the success of their teaching.

Carbonic Oxide Poisoning.

From a medico-legal point of view it is often of extreme importance to be able to obtain chemical proof of the presence of carbonic oxide in the blood. The classic test is by spectroscopic examination, which gives, or is supposed to give, the typical bands of carbo-hemoglobin. In practice, however, this test often fails, and several striking examples of such failure were recently brought before the French Biological Society by Dr. L. Garnier, of Nancy. Four men were asphyxiated by carbonic oxide, the intoxication proving fatal in three. In only one of the four was it possible to demonstrate the presence of the persistent bands of oxycarbo-hemoglobin. The absence of these bands, therefore, cannot be accepted as conclusive evidence that death was
not due to this cause, and the fact that they were not demonstrable even in the fatal cases confirms Marconi's view that carbonic oxide kills not only by fixing the haemoglobin, but also by provoking reflex paralysis of the cardiac and respiratory functions with consequent fatal syncope.

The Hygiene of Holidays.

The holidays are upon us. The coming of summer in all its ancient glory and rich in its vitalising heat arouses longings in the city dweller for the coolness of the mountains or the refreshing breezes of the sea, and oftentimes, under the almost irresistible desire for a return to the country impulse is allowed to override reason in the selection of what custom and fashion now term a "health resort." It is needless to add that many such stations are oftentimes selected with such a lack of hygienic forethought and absence of all medical advice that it is hardly to be wondered at that there lurks a rest and recuperation frequently not only gain no benefit, but are precipitated into such morbid conditions as they are endeavouring to avoid. It is remarkable how neglectful most thoughtful men are in the haphazard way in which they select, or sometimes allow to be selected for them by ignorant friends, holiday resorts, the chief end and aim of which should be the recreation of mind and body, and the rehabilitation of all the powers of resistance of the body against the insidious and ever-prevalent attacks of pathogenic influences. Every medical man can from his own personal experience adduce numerous examples where a reckless and altogether unreasonable impetuosity in the conduct of holiday life has awakened long slumbering mischief, broken down compensatory powers, opened channels for unprotected attack, deranged Nature's shielding mechanisms, and in many instances actually initiated disease processes which neither science nor art could subsequently arrest. The clear lesson is that, in the selection of a holiday resort and in the conduct of a holiday, hygienic principles should be allowed directing force. We are strongly of opinion that medical men, and particularly those who are still privileged to fulfil the honourable duties of a "family practitioner," might exercise a wide beneficial influence if they were more frequently consulted as to the manner and method of holiday-taking.

Suggested Walking Race for Nurses.

The craze for long-distance walking races is producing results of a quaint nature that must afford a good deal of amusement to the sporting gentlemen of the London Stock Exchange who were the pioneers of this entrancing form of recreation. The enterprising spirit of the modern business man has been fiercely stimulated by this species of bastard athletics, in which there clearly lurks a rich mine of potential advertisement. This view of the matter has been evidently recognised by the Eastham Ferry Pleasure Gardens and Hotel Company, Limited, who have sent a circular letter to the secretaries of the Liverpool hospitals, inviting nurses at those institutions to a "circular" walk of about five miles. Admission to the amusements, together with an invitation to free refreshments, was at the same time extended to all nurses in uniform, whether competitors or not. In certain quarters this circular has been, not unnaturally, regarded as an insult to the nursing profession. From an abstract point of view there is nothing, so far as we can see, that makes it more derogatory for nurses to walk over a given course than for a bevy of stockbrokers. At the same time, we feel that nurses would be better advised to keep aloof from such public exhibitions, nor do we feel the slightest doubt that abstention will be their absolute and immediate reply to the Eastham directors. It is to be hoped that a due sense of the fitness of things will keep nurses, just as it would naturally keep the clergy, medical men, Army and Navy officers, and barristers out of these much-advertised competitions.

Hampstead Heath and London's Health.

HAMPSTEAD HEATH is the most beautiful of London's health resorts. It affords refreshment for the body and invigoration for the mind, and its associations are rich in material for the energising of life's best emotions. We, therefore, strongly support Mrs. Barnett, of Toneyee Hall, in her public-spirited action in endeavouring to keep back the invading builder, and hope means will be speedily secured whereby the eighty acres of fields sloping away from the north-west corner of the Heath may be retained for the public service for ever. The wealth of London depends upon the health of London, and every effort which more firmly provides for the maintenance of the latter must necessarily add to the value of the former.

It is said that good private nurses are much needed in Upper India, especially in the Punjab, and we understand a movement is on foot to provide, on the co-operative principle, for this need.

PERSONAL.

DR. A. STANLEY GREN has been appointed medical officer of the Lincoln General Dispensary.

DR. ROBERT LYALL has been appointed Deputy-Coroner for North-East London.

DR. A. G. HAYDON, President of the Brussels Medical Graduates' Association, will preside at the annual dinner to be given on the 7th inst., at the Trocadero Restaurant.

LORD LISTER has been invested with the honorary degree of Doctor of Science of the University of London in recognition of his epoch-marking discoveries on the means of procuring asepsis of wounds.

DR. LORENZ, of Vienna, who is still pursuing his highly remunerative globe-trotting, was entertained the other evening at dinner by sundry senators and members of the Canadian Legislature.

MR. GRAVILLE KYLE, F.R.S., has been appointed full surgeon to the Bristol General Hospital vice Mr.
Barclay, deceased; and Mr. E. W. A. Groves has been elected Assistant-Surgeon to that Institution.

DR. N. J. HOBART, of Cork, who has retired from practice after a professional career of fifty-seven years, has been elected an honorary life member of the Cork Medical and Surgical Society.

DR. ANTHONY ROCHE, Professor of Medical Jurisprudence in the Catholic University School of Medicine, has been appointed to deliver a course of lectures on hygiene and public health at Maynooth College.

DR. SARAH BROIDO has been appointed medical officer to a steamer plying between Marseilles and Algiers, this being the first instance in which a woman doctor has gained a footing in the maritime service.

The Local Government Board has refused to sanction the dismissal of Dr. Reed, the Public Analyst for Islington, on the mere ground of his refusal to modify his fees for the examination of articles of food.

DR. A. FRANCIS DIXON, Professor of Anatomy at the University College of South Wales and Monmouthshire, has been selected to succeed Professor Cunningham in the Chair of Anatomy in Trinity College, Dublin.

DR. A. FRANCIS DIXON has been presented with sundry tokens of affection and esteem by the students of University College, Cardiff, on the occasion of his leaving for Dublin University.

It is stated that Sir Frederick Treves, F.R.C.S., has decided to retire from practice at the end of next month, a decision which, in view of his comparative youth, is certain to cause surprise not unmixed with regret.

DR. JOHN ROBERTSON has been selected from numerous candidates by the Health Committee of the Birmingham Corporation to succeed Dr. Hill as Medical Officer of Health for that city. Dr. Robertson is only forty years of age.

SIR FREDERICK WILLS, BART., M.P., will open the splendid library which he has given to the Medical School of Guy's Hospital on the 3rd inst. He will afterwards distribute the medals and prizes to the successful students.

The Hon. G. Hepburne Scott, M.A., M.D., Cambridge, has been awarded the Raymond Horton-Smith prize for 1903 for his thesis, his subject being "A Contribution, Based on Clinical Observation, to the Classification of the various Cells found in the Blood in Health and Disease."

SIR WILLIAM TURNER, M.D., F.R.S., has presented to the University of Edinburgh, for the use of his successors in the Chair of Anatomy and of the students in the anatomical department, a large stock of drawings, diagrams, and anatomical preparations, together with several microscopes and other instruments, and a number of books.

BIRTHDAY HONOURS.

The list of birthday honours comprises four knighthoods conferred on medical men, viz., Mr. A. D. Frpp, Dr. Stephen Mackenzie, Dr. P. Heron Watson, and Dr. E. C. Perry. There are two K.C.B.'s: Surgeon-General Colvin Colvin-Smith, late of the Indian Medical Service; and Surgeon-Major-General J. B. C. Reade, late of the Army Medical Staff; two C.B.'s: Surgeon-General J. H. Evatt, A.M.S., and Surgeon-General Adan Scott Reid, I.M.S. Dr. Patrick Manson has been made K.C.M.G., and Dr. Allen Hastings Hanley, of South Nigeria, has been appointed C.M.G.

SCOTLAND.

KNIGHTHOOD FOR DR. PATRICK HERON WATSON.—Scarcely any name is better known throughout the length and breadth of Scotland than that of Patrick Heron Watson, and its appearance in the Birthday Honours list will be hailed with pleasure by a wide circle of lay and professional friends. Dr. Watson, like many other distinguished Scotsmen, is a son of the manse, his father having been parish minister of Burntisland, where Dr. Watson was born seventy-one years ago. He graduated in medicine when just twenty-one, and his professional career was virtually begun soon after, when, the Crimean War having but recently broken out, he joined the Army Medical Service as staff assistant-surgeon, afterwards becoming assistant-surgeon in the Royal Artillery. For his services in the war he received the Turkish, Crimean, and Sardinian medals, and on reaching home settled in Edinburgh to practise and teach surgery. He soon became assistant, and then full surgeon to, the Infirmary, his term of office in the latter capacity expiring about twenty years ago, when he became, what he still is, a consulting surgeon to the institution. His hospital work, however, has been by no means ceased with his withdrawal from the acting staff of the infirmary, and, though he no longer teaches, he still remains in active charge of the surgical wards in Chalmers Hospital. He also examines in surgery for the College of Surgeons. Dr. Watson has held numerus and important public and medical appointments. He is a member of the General Medical Council, and represents the University General Council on the University Court; he is one of the Custodians of the Patrons of an University appointed by the Court; he was honorary surgeon to the late Queen in Scotland, and subsequently to King Edward; and was a member of the recent Universities Commission. Dr. Watson's reputation as a surgeon was built up while he was in active practice, not only of surgery, but of medicine; he belongs to the older school of surgeons who, holding surgical hospital appointments, are yet able to practise as physicians. He was renowned for his brilliance and boldness as an operator, and was the first to perform many of the major operations, among which excision of the larynx may be specially mentioned. He has written treatises on excision of the knee-joint and on venereal diseases, as well as other surgical topics.

HOSPITAL ACCOMMODATION AT PERTH.—As a result of a recent outbreak of scarlet fever, the Local Government Board had to investigate, through their medical officer, the whole question of hospital accommodation in Perth, and have just forwarded their inspector's report, with their comments, to the Perth Town Council. The present arrangement is that the Perth Royal Infirmary agrees to reserve twenty beds for scarlet fever and twenty for other fevers (excluding small-pox) for the city, the charge being £1 per week per patient. While this arrangement is satisfactory under normal conditions, it occasionally proves insufficient; and, as the small-pox, the present accommodation is very suitable as regards site, though the buildings are adequate. After full consideration, the Directors of the Infirmary are advised to exclude infectious diseases altogether and the local authority is recommended to build and manage a hospital for itself.

REQUESTS TO SCOTTISH MEDICAL CHARITIES.—Dame Anne Dawson Brodie, whose personal estate amounted to over £150,000, has left, subject to certain life-annuities, a sum of about £20,000, on condition that it be used for the benefit of medical students. The trustees may select. The institutions which she recommends as deserving are the Falkirk Cottage Hospital, the Royal Infirmary, the Sick Children's Hospital, and the Longmore Hospital for Incurables.

MEETING OF THE NEUROLOGICAL SOCIETY.—This
society met in Edinburgh on June 27th, when there was a large attendance of members from London and other parts of England. The proceedings included a demonstration of physiological and pathological cases in the University Physiological Department from 10 to 11.30, and an exhibition of clinical cases in the Infirmary from 12 to 1.30. The members dined together in the evening.

BELFAST.

THE ULSTER MEDICAL SOCIETY.—The annual meeting of the Ulster Medical Society was held in the Medical Institute, Belfast, on Thursday evening, June 27th, John Campbell, President, in the chair. The annual report was read by the hon. secretary, Dr. Houston. It stated that since the last annual meeting the society had been reorganized according to the new rules adopted at that meeting. Sixty new members had been elected, seven had resigned, and four had died. Through the medium of Sir Wm. Whittla, a handsome clock had been placed in the Lecture Hall of the Institute in memory of Dr. Dunlop. The total membership of the society in 1903 had reached to 209, a phenomenal increase being due to the opening of the Medical Institute and appreciation by the profession in Ulster of Sir Wm. Whittla's generous gift. The financial statement showed that the hon. treasurer had begun the year with a balance of £93, received £156, expended £271, and concluded the year with a balance of £178. The Institute has only been open six months, however, so that this year's accounts can hardly be taken as showing the normal expenditure of the society. The office bearers for 1903-4 were then elected, and are as follows, including the president, elected last year for two years, and the treasurers, who are permanent members of Council:—President: Dr. John Campbell. Vice- Presidents: Drs. Gardner Robb and W. D. Donnan (Holywood). Hon. Treasurer: Dr. W. B. McQuill, Pathological Secretary: Professor Lorrain Smith. Hon. Librarian: Dr. R. R. Leathem. Hon. Secretary: Dr. Thos. Houston. Council: Ds. Morrow, J. B. Moore, Professor Byers, Colville, Killen and Gausen, with the treasurers—Drs. Nelson, Campbell, Prof. Lindsay, Dempsey, McCaw, A. B. Mitchell, and Cecil Shaw.

lodging house, nursery, and medical attendance.—A new lodging house for men and a day nursery, erected in Matilda Street, were opened by Lady Henderson on Thursday, June 25th. The need of model lodging houses in the city has been strongly emphasized by a murder which took place a few days ago in a common lodging house in Belfast, in one room of which three families lived, the room being only 17 ft. by 12 ft. The need of day nurseries in a manufacturing town where many poor women have to work in factories and warehouses is obvious to all, and to none more than to the members of the medical profession, who see a fearful amount of disease in children due to neglect, as well as accidents due to want of care. A large open-air recreation ground has been wisely and generously provided beside the new building, which will be an immense advantage to the children. It was stated at the opening ceremony that the committee have made arrangements for the visit of some well-known medical practitioner once a week, thus providing medical attendance both for the children and their mothers. No doubt the committee is actuated by the best intentions in making these arrangements, but he will be a rash man who will undertake the medical treatment of infants on the strength of a weekly visit.

Correspondence.

CHLOROSES, COMPRESSION, AND GASTRIC ULCER.

to the editor of the medical press and circular.

sir,—The perusal of the remarks of Dr. W. Williams on chlorosis in The Medical Press and Circular of June 24th, induces me to offer a few observations bearing on the subject of gastric compression as a cause of severe dyspepsia and gastric ulcer.

Among my patients at Victoria Park Chest Hospital, I have met with cases of severe pain and obturation dyspepsia among gardeners. On inquiry as to habits I found that these men were often engaged after a full meal in work that involved a good deal of stooping and consequent compression of the digestive organs. Till this practice was abolished all medicines proved useless.

In one case that was brought to my notice by Dr. Wilton (formerly of Sutton), a gardener came to the surgery in the morning complaining of various dyspeptic symptoms. He got up to his work. In the evening he had a good deal of pain, suddenly fell into a state of collapse and died.

The post-mortem examination showed a very large ulcer perforating the stomach with an aperture through which I could pass my two fingers.

For young women, loose clothing and at first a milk diet are two points most properly insisted on by the author of the paper, as well as the administration of iron in one of its mildest forms.

Some months ago I had an opportunity of seeing how well this method answered in a most severe case of chlorosis that I sent to the Chest Infirmary under the care of Dr. E. H. Buckell. Recently I hear that this patient has had a relapse on returning to London, and is thought now to have gastric ulcer.

John C. Thorogood, M.A., F.R.C.P.,
Consulting Physician to Victoria Park Chest Hospital.

Bognor, June, 1903.

CANCER AND SMOKE.

to the editor of the medical press and circular.

sir,—In connection with the great liability of chimney-sweeps to cancer, it would be interesting to know whether any so-called "cancer-houses" in Streets or unions near any chimney which causes the air of apartments to be contaminated with smoke and sooty particles both in winter and summer. Similarly, the question would arise whether the increase of cancer in modern times could be connected with the growth of population, consequent extension of metropolitan areas, and resulting frequency of fogs saturated with smoke from densely packed houses.

I am, sir, yours truly,

Gordon Holmes, M.D.

Obituary.

WILLIAM CADGE, F.R.C.S.ENG., J.P.

The death is announced, at the advanced age of eighty-one, of Mr. William Cadge, who for many years was the best known, indeed the foremost, of provincial surgeons.

We cannot do better than reproduce the obituary notice prematurely published by the Times some years in error:—

"'Cadge of Norwich' has been a household word in the counties of Norfolk and Suffolk for nearly half a century, and no surgeon has been held in higher estimation than he since the death of 'Old Crose' of Norwich. Mr. Cadge, who came of a well-known yeoman family in Norfolk, served his articles in the Norwich and Norwich Hospital, and then went up to University College Hospital, when Robert Liston was at the height of his reputation as an operating surgeon. Mr. Cadge passed the College of Surgeons in 1845, and then became Liston's private assistant, and remained with him till his death in 1847, when Mr. Cadge contributed an account of his last illness and of the post-mortem examination to the Lancet. He then became demonstrator of anatomy in University College, and assisted Morton in producing his anaesthetic. In 1848 he became Fellow of the College of Surgeons by examination, and in 1850 he was
appointed assistant surgeon of University College Hospital in succession to Mr. Erichsen, who had been promoted to the post of surgeon. This appointment, however, Mr. Cadge did not hold long, for two years later, a vacancy occurring at the Norfolk and Norwich Hospital, he was invited to hold the position. In 1885 he was appointed surgeon at the British Museum and the Norwich Hospital gives abundant evidence of his skill in this department. Mr. Cadge married the sister of the late Sir Richard Quain, but had no family, and he was dead for many years. He practiced an active interest in municipal matters, and served the office of Sheriff of Norwich with success. He was a liberal supporter of his hospital, having on two occasions presented the charity with the munificent donation of £10,000. When he retired from the active duties of the staff he was elected consulting surgeon with the right, which he occasionally exercised, to occupy a few beds with his patients. Mr. Cadge was elected a member of the College of Surgeons of England in 1850, and held office for sixteen years, and was Hunterian Professor of Surgery in 1886, when he lectured on lithotomy and lithotomy, giving the test of his large experience.

Mr. Cadge was a munificently benefactor of the hospital and other local charities, and had been on the Commission of the Peace since 1875.

**Medical News.**

**The New Dagenham Consumptive Sanatorium.**

On Thursday last this sanatorium, which is beautifully situated at Dagenham, Essex, and some two miles from the Woburn Sands Railway Station, was formally opened. It has been given, fully equipped and completed, together with the freehold of the land, by Mr. H. L. Bischoffsheim. The sanatorium has been specially erected for the gratuitous treatment of the Jewish poor, to meet the difficulty of providing for them an institution where their customs and religious principles will be respected. A special train took a party to the opening ceremony. This included, among others Mr. and Mrs. Bischoffsheim, Sir Maurice and Lady Fitzgerald, the Countess of Desart, Sir Douglas Powell, M.D., Sir Felix Semon, Mr. and Mrs. Macnaughton, Mr. and Mrs. Goldschmidt, and Mrs. Headley. The sanatorium is beautifully situated over four hundred feet above the sea level, on a well-wooded hill, and is surrounded by pines. The building, which is constructed to accommodate twenty-two patients (fourteen male and eight female), with the necessary rooms for a complete staff, has been completed after careful consideration of every modern requirement for the open-air treatment, and no necessary detail has been omitted either in the structure itself or the fittings. All the rooms used by the patients, the corridors and verandah, have floors of polished teak. The ceilings and walls are painted, and every angle in the building, vertical and horizontal, has been covered, while the walls of all bathrooms, lavatories, the daisies to corridors, the kitchen, larders, &c. are lined with glass wall tiles. The fixed baths are of white glazed porcelain, forming part of the room structure, and are in the form of tubs with the water placed. The sewage is dealt with at its outlet, over 300 yards from the institution, by a septic tank, which has been constructed by the Septic Tank Syndicate of Engineers. For the two wells, 164 ft. and 70 ft. deep respectively, yield 800 gallons of excellent water per day, and provision is made by underground tanks for the reception and storage to 10,000 gallons of rain water, and all the services are so arranged that this water can be used for flushing the toilet. The building is lighted throughout with electricity, and electricity has also been used for power purposes. A hundred feet away from the main structure is a building containing boiler, engine, and accumulator houses, with wet and dry laundries, store, and disinfection rooms. Here 200 lbs. of water per hour can be evaporated, and steam supplied for the engine, the laundry, and the disinfector. The steam is also used for the drying room, and a flue is carried underground to a shaft in the main building, and the draught being assisted by an electrical blower fitted in the engine room. The wells are fitted with three throw pumps, driven by electric motors, supplied with automatic starting and electric water gauge. In this detached building everything needed is provided for lighting and heating the sanatorium in winter, as also for laundry and disinfection purposes. The steam steriliser is worked by an electric motor to 260°. It is also proposed to have a dry steriliser for special articles. The whole of this building is lined with glazed tiles from floor to ceiling.

A feature in the internal details of the sanatorium specially worth noting is that all pains have been taken to reduce the dust trouble to the lowest minimum. The wardrobes in the patient's bedrooms are constructed to be taken quickly apart, so that the wall behind and the floor under each can be exposed and easily cleaned.

On the south side of the sanatorium an outlying verandah of sufficient size to accommodate the whole number of patients has been erected. The entire installation reflects the greatest care bestowed on the work. The builders (Messrs. Foster and Dickson, of Rugby), the sanitary engineers (Messrs. Dent and Hellyer of London), the electrical engineers (Messrs. Baily, Grundy and Company, of Cambridge), and the laundry engineers (Messrs. Mitchell, of Glasgow), while the whole arrangements have been designed and supervised by the architect, Mr. Richard Phillips, of London.

In this munificent gift to the Jewish community, Mr. Bischoffsheim has set an example which might worthily be followed by others who are richly endowed with this world's goods, not only by the foundation of sanatoria for consumptives, but of those for the treatment of other forms of disease, which are equally needed. The local physician to the sanatorium is Dr. Wright Grant, and the consulting physician is Dr. Horton Smith.

**The Gordon Fund.**—The Attempted Blackmailing Case.

We wish to direct our readers' attention to the fund which has been instituted to help to defray the heavy legal expenses of Dr. Almond Gordon who was put on trial recently for the case of blackmailing. The Crown do not so far appear to have taken any steps to punish the guilty party, and it is for the medical profession to show that they are determined to stand by a professional brother in such a case. We have so far received the following subscriptions:—F. T. Heuston, F.R.C.S., £5 5s.; Trevor N. Smith, F.R.C.S., £1 1s.; R. W. Harley, M.D., £2 2s.; W. J. Thompson, M.D., £1 1s.; James Little, M.D., £5 5s.; R. J. Wayland, F.R.C.S., £2 2s.; Andrew Horne, F.R.C.P., £3 3s.; Sir John Moore, M.D., £1 1s. We shall be glad to receive and acknowledge further subscriptions.

**Central Midwives Board.**

A MEETING OF the Central Midwifery Board was held at the Privy Council Office, Whitehall, on Thursday, June 25th, at the instigation of Dr. Kaye, the County Medical Officer for the West Riding, on behalf of a conference of county medical officers lately held, suggesting that the Board should receive a deputation from the Conference in the latter with a view to the administration of the Act in county areas. The proposal was favourably received by the Board and the secretary was instructed to arrange a meeting in London at an early date. On the Midwives' Roll was approved, and the Board decided that the certificate should in each case show the face of the qualification in respect of which it was granted. The appropriate forms were approved and adopted.
NOTICES TO CORRESPONDENTS.

JULY 1, 1903.

NOTICES TO CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initial, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

SANITATION AND RELIGION.

The eleventh Annual Meeting of the Church Sanitary Association was held on Wednesday at the Church House, Westminster, in the unavoidable absence of Dr. W. Collingridge, Medical Officer of Health for London, who was detained by urgent business in Bradford. The chairman, Mr. J. A. Colls, was succeeded by Mr. C. W. Hargreaves, the retiring president. Dr. Schofield moved the following resolution, which was carried unanimously:—"That parents, preachers, and teachers in all parts of the country are urged to intimate systematically the Christian obligation of endeavouring to secure for pure, all air, fresh water, and food, the best conditions for the health and well-being of the people," Mr. Northcott, the secretary of the Garden Cities Association, moved, and Mr. Saxen Snell seconded the resolution. —That this meeting desires to give experimental proof of the imperious need of fresh legislation in respect of the better housing of the working classes and better sanitation generally. The resolution, which was supported by Dr. Waldo, Coroner for the City of London, Dr. Hooker, and Mr. Arlidge, secretary of the Housing of the Four Assoriance, was carried unanimously.

L. M. G.—We shall be pleased to receive subscriptions for the purpose mentioned if a proper consent is obtained, and the matter placed on a business basis.

T. F. writes more satisfactorily to both parties if you referred the question to an expert. There can be no arbitrary standard for the valuation, the value of practices varying according to circumstances. There is one point, however, the two others are so clear cut and dab, and afford safeguards alike to the vendor and purchaser.

M. S. to Y. —Your foreign experience does not confer the right to practise in this country: that is to say, it does not convey the recognised medical qualification. It is not for me to advise you how to evade the law, nor would you be wise to attempt to do it.

M. R. G. S. —Your letter is crowded out at "press," and will appear in next number.

Meetings of the Societies, Lecture, &c.

WEDNESDAY, JULY 1st.

OBSTETRICAL SOCIETY OF LONDON (20, Hanover Square, W.)—8 p.m. Specimens will be shown by Dr. R. Andrews, Lieut.-Col. Stormer, and others. Short Communication:—Mr. H. J. Curtis (introduced by Mr. W. D. Burgoyne).—Mr. W. Burgoyne and Mr. A. W. H. M., Surgeon to the National General Hospital, to the Royal Hospital, London, have been under treatment for over 12 months, for "Grasp-like" Sarcorna of the Cervix, Fibroids, and Inflammation of the Uterus, the Vagina (with specimen).—Mr. A. W. H. M. on the Excision of Ophthalmo-lipoma Neuroptomy (opened by Dr. E. Stephenson, introduced by Dr. Griffith).—Mr. W. G. Albro and Mr. J. C. Callin, Clinical and Colostomy. 

THURSDAY, JULY 2nd.

NORTH-EAST LONDON CLINICAL SOCIETY (Tottenham Hospital, N.)—4 p.m. General Meeting.

BOSTON SOCIETY (20, Hanover Square, W.)—Annual General Meeting. Report and Balance Sheet. Election of Officers for the ensuing session.

OBSTETRICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos Street, Cavendish Square, W.)—8 p.m. Card Specimens will be shown by Mr. W. C. Rockcliffe, Mr. J. H. Parkinson, and Dr. L. Buchan. 8.30 p.m. Papers.—Dr. L. Buchanan: Kertanis, with Special Reference to the part played by the Cornal Cells.—Mr. W. C. Rockcliffe: Ovarian Fibroids.—Mr. G. W. Denton: General Papillomata and Cornal Papillomata of the Corn.—Mr. S. Smell and Mr. E. T. Collins: Three Cases of Placentoma of Temporal Region, Orbit, Eyelids, and Ears.—Dr. A. Whitfield: Pneumonia (Post-Graduate Course).

SATURDAY, JULY 4th.

PATHOLOGICAL SOCIETY OF LONDON (Pathological Laboratory, South Kensington, S.W.)—4 p.m. to 6 p.m. To be continued.

Appointments.

Harry, W., M.B., M.S. Abergavenny, Medical Officer of Health for Wetherby, Yorks.

Appointments for the Derbyshire Hospital for Sick Children, Derby.

Booke, Antony, M.R.C.P., L.R.C.P.Irel., Professor of Public Health, Catholic University Medical School, Lecturer on Public Health to Maynooth College.

Rudd, W. A., M.D.Durh., M.R.C.S.Eng., L.R.C.P.Lond., Divisional Surgeon to Metropolitan Police. 5 p.m. to 6 p.m.

Serpell, H. Hamilton, M.R.C.S., L.R.C.P. Lond., Assistant House Surgeon to the Severn Devon and East Cornwall Hospital at Plymouth.

Sunderland, Septimus, M.D.Brunx., M.R.C.P.Lond., Obstetric Physician to the French Hospital, Shaftesbury Avenue.

Vacancies.

Baltimore Union.—Medical Officer for Kitson Dispensary District Salary £120 per annum, with registration and vaccination fees &c. Applications to the Hon. Secretary.

Borough Hospital, Birkenhead.—Junior Male House Surgeon. Salary £120 per annum, with board and washing. Applications to the Hon. Secretary.

Cumberbatch and Borough Infirmary.—Resident House Surgeon. Salary £120 per annum, with furnished apartments, board, attendance, fire and gas. Applications immediately to W. Powell Price, Secretary, & The Birkbeck, Birkenhead.

Cromarty.—Medical Officer. Salary £110 per annum, with furnished apartments, board, attendance, fire and gas and washing. Applications to Howell Powell, Secretary.

Croydon Asylum and Mental Hospital.—Senior Assistant Medical Officer. Salary £300 per annum, with board, lodging and washing. Applications to the Medical Superintendent, Croydon Mental Hospital, Warrilong, Surrey.

Liverpool Dispensary and Community Hospital. Salary £100 per annum, with board and apartments. Applications to Sam B. Leicester, Secretary, 56, Vauxhall Road, London S.W.

London County Council.—Visiting Dentist to Industrial Schools. Salary £150 per annum. Applications to G. L. Gomme, Clerk of the Council, Spring Gardens, S.W.

London County Council.—Woman Inspector under the Infant Life Protection Act. Salary £100 per annum. Applications to G. L. Gomme, Clerk of the Council, County Hall, Spring Gardens.

New High Level Bridge and Tyne Viaduct.—Medical Officer. Salary about £200 a year. Applications to Cleveland Bridge and Engineering Co. Ltd., Gateshead-on-Tyne.

The Royal Hospital for Children and Blind, Bathroom Road, Tooley Street, London S.E.—Dispenser. Salary £104 per annum. Applications to the Secretary.

Trinity College, Dublin.—Professor of Chemistry. Applications to Benjamin Williamson, Registrar, Trinity College, Dublin.

University of London.—Academic Registrar. Salary £200 per annum. Applications to Arthur W. Rickett, Principal, University of London, S.W.

University of London.—Secretary to the University Extension Regius Professorship. Salary £200. Applications to Arthur W. Rickett, Principal, University of London, South Kensington, S.W.

Urban District Council of Wilton.—Bagley Sanatorium. Resident Medical Officer. Salary £250 per annum, with board, residence, &c. Applications to Albert Roberts, Clerk to the Council, Town Hall, West, Didcot, near Manchester.

York Dispensary.—Resident Medical Officer. Salary £120 a year, with board, lodging and attendance. Applications immediately to W. Draper, Esq., Grey House, York.

Births.

Coleb.—On June 26th, at 55, Upper Berkeley Street, London, the wife of E. H. Coleb, M.D., of a daughter.

Rush.—On June 26th, at 30, St. James's Road, Higher Crumpsall, Manchester, the wife of John Rust, M.R.C.S., L.R.C.P., of a daughter.

Knox.—On June 26th, the wife of John E. Knox, M.B., of Redlands, East Moyleston, of a son.

Marriages.

Carruthers.—Market.—On June 30th, at Christ Church, Llandraf- rchan, John Carruthers, M.D., of Rock Ferrry, to Bessie Gertrude, youngest daughter of Mrs. Massey and the late C. W. Massey, of The Woodlands, Rock Ferry, Chester.

Way.—Bullock.—On June 9th, at St. John's Church, Westminster, Montague Way, L.R.C.P. Lond., of Kenilworth Lodge, Southsea, to Mary, youngest daughter of the late Thomas R. Turnball, of St. Giles, Barnet, and the late Tamble, of Streatham Hill, S.W.

Worsnop.—La Boss.—On June 9th, at St. Jude's, South Kensington, George Vigers Wornington, M.A., M.B., B.Camb., of New, Gloucesterhire, eldest son of James Copland Wornington, Esq., of Lowndes, Northwood, to Emma Mary, only daughter of Francis Aubrey Le Boss, late of Norbiton, Surrey, and Mrs. Le Boss, of 3, York Mansions, S.W.

Deaths.

Cadot.—On June 26th, at Lowestoft, William Cadot, F.R.C.S.Eng. L.S.A., Consulting Surgeon to the Norwich and Hospital in the last year of his life.

Woodman.—On June 22nd, at his residence, E. Chichester Place, Kingston-on-Thames, to John Woodman, M.D., F.R.C.S., in his 67th year.
The Medical Press and Circular.

The Cavendish Lecture

ON

DISEASE OF THE ASCENDING AORTA.

By T. CLIFFORD ALLBUTT, M.D., LL.D., F.R.S., F.R.C.P.,

Regius Professor of Physic in the University of Cambridge.

(ABSTRACT.)

In a little tract of the brain, one so small that an infant might grasp it, lies the engine of all that makes life worth living; and but a few inches below it, where brain and spine unite, is a still smaller tract, where lies the knot of life itself. The upper tract has its times of energy and of repose, by sleep its ravelled sleeve is knitted up; but the knot of life itself knows no pause, no quiescence; let its vigilance be at fault for a few seconds, and the busy frame it governs will go into silence. Save as a lesson in physiology these are strange parts of us; yet there is another unsleeping minister of life, our familiar, of whose pulses Harvey was rapt into saying that they "are of the spirit of the blood acting superiority to the powers of the elements . . . . and that the soul in this spirit and blood is identical with the essence of the stars." When the pulses of this instrument beat in harmony we feel within us that all is well; when they are jangled and out of tune we are dismayed. Often when in the still night I hear, as I lie, the calm and continual rhythm of my familiar spirit ever winnowing boon from bane, I am lost in wonder at the long procession of these notes of human time, at this perpetual beat of the manifold tides of life.

“Tireless, as it seems, tireless and everlasting, yet it will cease; nay, when youth is past, in every beat there may be an irreparable wound. Hour after hour the blood leaps against the vault of its conduit, strain- ing the bonds of it, searching its strength, testing its elasticity. Nevertheless, the endurance of the arch of the aorta under the incessant lashing of the blood for three-quarters of a century is astonishing in some old persons in whom a constant immunity from toxic influences has coincided with some inherited tenacity of structure. We expect, however, to find in the aorta of persons after the age of fifty, and usually we do find, no inconspicuous signs of these years of stress. And, again, as we should expect, it is in the arch of the aorta more than in any other arterial tract that these signs of injury prevail; and prevail more densely and widely in persons whose lives had been spent in strenuous muscular labour.

Such being the conditions under which the work of heart and aorta are performed, the stress upon the first or curved portion of the great vessel being thus heavy and perpetual, while we admire its tenacity we shall presume that, whatever the injurious influences to which it may be obnoxious, stress must enter for more or for less into the sum of the lesions, and into the election of their seat or seats of greatest severity.

With aortic disease beyond the thorax we are not concerned. In that part which does concern us we find the effects of mechanical stress upon a vessel reduced in tissue resistance, it may be, by alcohol and attacked by syphilis, and to this stress we shall attribute the pouching of the arch and the intensification of the subinflammatory lesions as may be due to the incessant agitation of an afflicted organ which needed rest, but to which rest was forbidden. For this reason disease of the aorta has always an additional if an incalculable element of gravity; and experience suggests to us that no lesion, however slight and intimate, can be wholly repaired. Arteritis is a proliferative rather than an exudative inflammation, and one tending to degeneration; by its growth and condensation, a patch of disease may, in favourable cases, undergo a slow compensation, and become a patch of repair; in some such way the damaged wall may resist destruction for an indefinite time; but restitution ad integrum, or even physiological efficiency on the assumption of an uninjured life, is contrary to experience.

Syphilis, however, is but one poison out of many by which the integrity of the arch of the aorta may be imperilled. It is ascertained that the aorta enjoys no complete immunity from the attacks of the ubiquitous bacterium, although of the kinds and degree of its liability we are still in much ignorance. We may anticipate that the self-purifying virtues of the blood and the scour of the aortic stream give the arch considerable advantages against microbial invasion; and that, if infection of it occur, it will occur under conditions of high blood impurity and high microbial virulence. A circulating poison, whether inorganic such as lead, evil humors such as gout, or virus such as that of syphilis, apt to enter into chemical relations with the wall of the vessel would seem to be fraught with a greater peril to it than the microbe which would be chased along water currents to settle in regions of sluggish irritation.

Disease of the aorta has not only a certain independence of disease of the heart, but also of the aortic valve itself. When we speak of diseases of the "aortic area," we mean, no doubt, something wider than the arch of the aorta; we include the mouths of the coronary arteries, the valve, the base of the heart, and the large anterior limb of the mitral valve; the smaller limb being related rather to the auricular side of the heart. We observe that the larger mitral limb is often associated in disease with the aortic valve, whereby it comes about that mitral disease may follow aortic disease; nevertheless, when we consider the aortic area within itself, we shall see that disease of the base of the aorta may not invade the valve, or involves it gradually and secondarily, and from above. Clinically, moreover, disease of the arch of the aorta forms a chapter apart from that of the heart, as we shall presently see more at length.

Acute aortitis is not always the perilous disease we are disposed to assume it to be. It is one of my purposes to emphasise the duty of careful heed to the state of the vessel in diseases wherein aortitis may enter and depart unawares. That acute aortitis is apt to arise in the course of infectious diseases, even in the course of the milder exanthems, rests upon a
collection of facts now large enough to carry conviction in this kind, and which, however, appear to be no accidents, but integral, if not common, terms of our series; terms which range in significance from transient disorders to terrible and even mortal calamities.

Of acute aortitis as a function of microbes, known or unassayed, the ministry of the infections, is more frequent than we are wont to suppose. The affection is often mild in degree, transient in time, and so secret in its approaches, that for the most part it is revealed only to him who is on the watch for it. In some cases it seems to determine a fatal issue, but as it usually appears in hemorrhagic cases, or cases otherwise of gravity, the effects of the aortitis cannot often be estimated precisely. In favourable cases of various aortitis all evidences disappear in a few weeks.

It is remarkable that in an infection so trivial as measles the intercurrence of acute aortitis of a mild and transient kind is by no means rare, if we may judge by the testimony of physicians so well known and so faithful as Samuel West. In scarlet fever, again, we have the authority of Landouzy and Sireday to testify to its occurrence, and this the more commonly perhaps for the well-known cooperation with scarlet-fever of a process very like acute rheumatism, not only in its aortic, but also in its endocardial manifestations.

Acute rheumatism prevails no doubt rather in the mitral area; but of its power to attack the aortic area, and the aorta itself, we are all well aware, not only in its aortic, but also in its endocardial manifestations.

From acute rheumatism we pass easily to the more malignant forms of cardiac inflammation, and here again we find the aorta by no means outside the sphere of the virus. Among others, the well-known case of perforative aortitis of Oliver and Woodhead the B. anthracis was detected in the parts diseased. These perforating cases, in which the disease penetrates rather than diffuses itself, are not very rare; though we are not so few of them the bacteriological evidence of Oliver and Woodhead. Perforation may make its way into pericardium, pulmonary artery, or auricle, as records in my possession have proved. It seems probable that some peculiar cases of aneurysm may take their rise in such a process. Suppurative aortitis seems to be rare, or as apt to be overlooked after death, as it does not break into the channel of the vessel. The pus lies in foci in the adventitia, and in the substance of the middle coat; it is a pericardial affair, and usually but a small and secondary item in some more extensive pyemia, as, for example, in some recorded cases of puerperal fever. But inner aortitis, of the kind which occupies our attention in this element of septic maladies.

The occurrence of aortitis in typhoid fever might appear more frequent were it more diligently sought for, for in this malady, as Louis first pointed out, aortitis presents itself in its benignant and transitory form. In typhoid we look for the specific aortitis, rather in the peripheral arteries; but Pottain has published two definite cases of typhoid aortitis, and not a few more are on record. Gilbert and Lion have produced in aortitis experimentally. The episode, for it is rarely much more, occurs during the later weeks of the fever, or even during early convalescence, when it is very likely to escape observation.

The occurrence of aortitis in the course of influenza, or during convalescence, has been so well and recently described by Dr. Sansom, that I may not detain you on this section of the subject. Of aortitis following diarrhoea I will only say that a recent record. That aortitis may arise in pneumonia, not as a direct extension of this disease, but as a several function of the pneumococcus, seems probable from certain observed facts, which do not rest upon the well known testimony of Lancereaux alone; Hervé has published three cases, and Sansom, adding another, has observed a frequency of occurrence. Sansom has recorded such a case in a lady in whom gout, rheumatism, syphilis and other known causes could be excluded. Nevertheless, as this form of aortitis is not always severe, but, as Mr. E. J. France points out, is apt to linger for years and to leave permanent lesion of vessel or valve behind it, we may, I think, congratulate ourselves on its apparent infrequency.

Syphilitic aortitis of the aorta, of Blumner, Blumer and others. Tubercle, only too common in small arteries, and in those of the brain, lung, or kidney, is rare in the large; and especially rare in the aorta, where its presence is rather curious than important. Its patches are distinguished from syphilitic patches by their greater propensity to caseation. The epithelium long remains intact. Blumer readily demonstrated the specific bacillus in both his cases.

Syphilitic aortitis I have left to the last, as being the most important of all the forms of aortitis. Indeed, it is now so well known that I may spare you any long account of it. General syphilitic arterio-sclerosis I can set aside, as lying outside of my province to write. Syphilitic aortitis, I now admit, is not necessarily associated with the general arteritis, though in the large majority of cases the aortic and the general disease occur together. Our attention is at present directed to acute aortitis, but the inflammation in syphilis is usually chronic; for instance, the virus was recognised by Hodgson as a cause of his cases of aortic dilatation, and as an element in the formation of the aneurysm it is too well known to need emphasis. But some cases of syphilitic aortitis are of rapid course, and may do grievous damage before the later phases of extensive chronic disease and dilatation are established.

Mr. Welch, formerly a Professor of Pathology at Netley, that we owe our best essay on this subject. Mr. Welch reported 117 cases of fibroid aortitis, and of these 46 per cent. had a record of syphilis. Again, of a series of 56 cases of fatal syphils 34 presented aortic lesions, mostly severe. In syphilis the aortic disease is usually of the tertiary period; i.e., it arises from the third to the tenth year of the disease, or even much later. A few present the appearance of gummata, but many have no such characteristic appearance; they are circumscissed, cicatricial, and warty. In persons of and after middle life, as Welch pointed out, we have no means of clear distinction in many cases, at any rate, between syphilitic and atheromatous. If extensive, it is apt to produce Hodgson's dilatation; if circumscissed and penetrative, aneurysm. Mr. Welch's opinion was withstood at the Royal Medical and Chirurgical Society, and it must be gratifying to him now to see it generally accepted. Mercury and the iodides mitigate and sometimes cause the disease; it is as important in certain cases of aortitis to give the patient the chance of them, as it is in certain cases of cerebral disease.

That in some cases of aortitis we have to deal with mixed infections is probable; but we have little definite information on this point.

Of acute aortitis as a result of lead or other mineral or vegetable poisons, I have no notes; nor can I profitably discuss some obscure cases in which muscular stress may have set up a primary aortitis in a vessel which, hitherto, both resisted and tolerated. It is difficult to operate with more insidious causes of aortitis—acute or chronic—I have already said; but I can call to mind only one case in which mechanical stress seemed clearly to have originated the mischief, since that some instructive work has been done. The pneumococcus, the B. coli, Eberth's bacillus and other...
An aneurysm of the aorta is so large and prevalent a part of aortic disease that I must omit it from this address. It is an aneurysm, too small for direct observation, which are apt to form about the root of the vessel, and are usually due to aortitis. In this area receses of various aortas are commonly found. Blood, lymph, or even air is sometimes sent through the sinuses of Valsalva; some of these are too shallow to contain clot, others retain clots of nominal substance, other pouches again are narrow-mouthed and aneurysmal in the sacular sense, and tend to rupture at once, causing death and death of the heart. These aneurysms, not to be detected during life, unless it be by the X-rays, occasionally give rise to signs of aortic disease and to symptoms of angina pectoris. Moreover, like other lesions of the vessel, they are apt to retard the pulse rate, a phenomenon not altogether dependent upon interference with the coronary circulation, on which vital matter I cannot touch in this lecture. Of other elements in the causation of chronic aortitis I may touch so far upon gout as to say that chemical research fails to discover urate in the aorta of gouty bodies, and that experimental injection of uric acid have no effect upon the aorta; therefore to attribute the disease to silting up of the vasa vasorum urate crystals must share the fate of many another ingenious suggestion. Concerning the poison of lead, I may say, that in such cases aortic disease may occur.

Many authors have called attention to the association of chronic disease in the aortic area—be it arteriomaticus, aneurysmal or valvular, with tabes dorsalis and with general paralysis of the insane. The factor of syphilis counts for much, no doubt, in this experience; and in yet more cases we may find a general arterio-sclerosis with less eminent aortic disease, and may have, moreover, to discriminate between the symptoms of aortic disease itself, cardiac disarrangement under general arterial disease, and tabetic crises.

Time will not permit me to trouble you with the histology of aortitis or atheroma, nor indeed is it needful. By the aid of many observers, French, German, English, and American, the subject has been minutely investigated and is fairly well known. The gelatinous patch is characteristic of acute aortitis, as for example in infectious varieties. Gelatinous patches in the neighbourhood of atheroma indicate acute phases in the course of a chronic process.

(To be continued.)

SOME REMARKS ON CORSETS.

By W. E. FOTHERGILL, M.A., B.Sc., M.D., Assistant Physician to the Northern Hospital for Women and Children, Manchester; Lecturer in Obstetrics, Owens College.

The Medical Press and Circular for June 24th, 1903, contains a most interesting article entitled "Some Remarks on Corsets" by Dr. William Williams. The author asks why chlorosis is a disease of young females; why the general condition as regards flesh is not materially affected as well as that of the blood; and why they recover so quickly on the adoption of loose clothing, low diet, and mild purgatives? His answer begins as follows—

"Taking the above questions in the order they come, the only answer forthcoming to the first, that women are clothed differently to men, and that young women or girls, not having become as yet accustomed to tight lacing, continue to suffer until their shapes are permanently altered, and the abdominal organs have become acclimated to girth. Most girls give in all rapidly on the advent of puberty, and such subjects would suffer most from a corset fixed in size, to say nothing of the fact that stoutly inclined young women would be just the ones to entertain
most anxiety about the size of their waists, and to take most pains with them. As to the general condition in regard to flesh being unaffected, or not so much so, and the rapidity with which recovery takes place, the explanation, I think, must be that the altered state of the blood cannot have been of very long duration."

I have read the above with peculiar pleasure, because I believe Dr. Williams to be perfectly right. Some time ago my own observations led me to write in a similar sense. Thus I find, on page 491 of my "Manual of Midwifery" (a) it is stated: "Innumerable women doubtless alter the outward conformation of their bodies, and also the shape, size, and arrangement of their livers and other viscera, without causing any derangement of health which can be directly traced to tight lacing. In any variation from health, however, the liver is the organ against which the patients, toxemias, and dyspepsias, are most slow to recover, and often prevents complete restoration. In short, the fashion weakens the strong, and may cause positive disease in the weak. Take, for example, the common form of anæmia known as chlorosis. As to sex, this condition is practically confined to young persons of both sexes. At all ages, it is commonest in the decade following puberty. It occurs mainly in young women and girls who live by bodily work, and accordingly have, as a rule, good muscular development. Again, chlorotic women are well nourished in general. They belong to a class which feeds well, though not always judiciously, and if starved it is not by want of food, but by inability to digest it—by the dyspepsia which is secondary to the anæmia. The condition is not hereditary. What is the prime factor in its causation? I have made a habit of measuring the waists of anæmic patients, who appear very often as out-patients at hospitals for women. Two measurements are taken, one over the corset, one after it has been removed. The result of prolonged observation shows that the waists of young women of the working classes measure on an average three inches more without the corset than with it. The patients are never conscious of any compression, and firmly believe that their clothes are loose. If, however, they are known to be recovering, after three weeks, the waist measurement increases, and the pressure of the corset is plainly felt for a few days after ordinary clothing is resumed. I believe the sequence of events to be as follows:—The 'grown-up' corset is adopted at the age of puberty, when the girl is thin and undeveloped. During the years that follow the chest and the pelvis enlarge, but the waist is not allowed to increase proportionately. Many a big young woman will state with pride that her waist measurement has not increased since she was a girl. It has not had the opportunity of doing so! Now, the working classes tend, by breeding and occupation, to be more thickset than the middle and upper classes. Their daily labour tends to develop the chest and cover it with muscle. Their waists should be larger in proportion; but the working girl thinks even more of a slim waist than does her more highly educated sister. When it is fully developed, the corset is cut, and matters of food, attention to the action of the bowels, fresh air, and bathing, the more intelligent portion of the population is more careful than the lower, the occurrence of chlorosis as a disease of the working classes is very largely explained. Compression of the liver, stomach and intestines causes constipation and dyspepsia; these are increased by indoor life in house or workshop, and, Anæmia of this kind is a frequent forerunner of toxemias during pregnancy."

I have by me some manuscript on a cognate subject, hitherto unpublished, part of which I may offer in support of the conclusion briefly expressed by myself in the above lines, and worked out by Dr. Williams in his recent paper. My notes are as follows:—

"Innumerable women doubtless alter the outward conformation of their bodies, and also the shape, size, and arrangement of their livers and other viscera, without causing any derangement of health which can be directly traced to tight lacing. In any variation from health, however, the liver is the organ against which the patients, toxemias, and dyspepsias, are most slow to recover, and often prevents complete restoration. In short, the fashion weakens the strong, and may cause positive disease in the weak. Take, for example, the common form of anæmia known as chlorosis. As to sex, this condition is practically confined to young persons of both sexes. At all ages, it is commonest in the decade following puberty. It occurs mainly in young women and girls who live by bodily work, and accordingly have, as a rule, good muscular development. Again, chlorotic women are well nourished in general. They belong to a class which feeds well, though not always judiciously, and if starved it is not by want of food, but by inability to digest it—by the dyspepsia which is secondary to the anæmia. The condition is not hereditary. What is the prime factor in its causation? I have made a habit of measuring the waists of anæmic patients, who appear very often as out-patients at hospitals for women. Two measurements are taken, one over the corset, one after it has been removed. The result of prolonged observation shows that the waists of young women of the working classes measure on an average three inches more without the corset than with it. The patients are never conscious of any compression, and firmly believe that their clothes are loose. I believe the sequence of events to be as follows:—The 'grown-up' corset is adopted at the age of puberty, when the girl is thin and undeveloped. During the years that follow the chest and the pelvis enlarge, but the waist is not allowed to increase proportionately. Many a big young woman will state with pride that her waist measurement has not increased since she was a girl. It has not had the opportunity of doing so! Now, the working classes tend, by breeding and occupation, to be more thickset than the middle and upper classes. Their daily labour tends to develop the chest and cover it with muscle. Their waists should be larger in proportion; but the working girl thinks even more of a slim waist than does her more highly educated sister. When it is fully developed, the corset is cut, and matters of food, attention to the action of the bowels, fresh air, and bathing, the more intelligent portion of the population is more careful than the lower, the occurrence of chlorosis as a disease of the working classes is very largely explained. Compression of the liver, stomach and intestines causes constipation and dyspepsia; these are increased by indoor life in house or workshop, and, Anæmia of this kind is a frequent forerunner of toxemias during pregnancy."

SHOULDERS FREE FROM WEIGHT. WHERE IS THE BELT FASTENED? IT DOES NOT ENCIRCLE THE WAIST OR SOFT-WALLED MIDDLE PORTION OF THE BODY BELOW THE RIBS AND ABOVE THE ILIAC CRESTS. IF WORN THERE TIGHT ENOUGH TO SUPPORT THE HEAVY TROUSERS IT WOULD PRESS UNCOMFORTABLY ON THE ABDOMINAL VISCERA. IT IS THERE WORN OVER THE BONY PELVIS, WHERE UNDERWALLS PROTECT FROM ITS PRESSURE THE ORGANS WITHIN.

THE NAVVY’S LEATHER BELT IS WORN LOW, PASSING BELOW THE ANTERIOR SUPERIOR ILIAC SPINES ON EITHER SIDE, MUCH IN THE POSITION OF A HERNIA TRUSS. IN THIS POSITION A BELT PASSES OVER HARDLY ANY MUSCLE, AND IMPEDES NO MOVEMENT, NOR DOES IT COMPRESS ANY INTERNAL ORGANS. THIS IS APPLICABLE TO SKIRTS OR TROUSERS WORN BY WOMEN IN MANY ORIENTAL COUNTRIES. THE MOORISH DANCER WEARS A SHORT SKEWER COVERING THE SHOULDERS AND CHEST, AND A DIVIDED SKIRT WHICH BAND RESTS ON THE HIPS BELOW THE ILIAC CRESTS, THE MIDDLE SOFT PORTION OF THE BODY BETWEEN THORAX AND PELVIS BEING LEFT UNCOVERED OR PROTECTED BY A SOFT GARMENT WHICH RESTS ON THE UNDERWALLS. THE HINDI WEARING THIS IS THE EASTERN ORIENTAL.

IT MUST BE ALLOWED, HOWEVER, THAT FASHION IN CORSETS HAS OF LATE MADE A MOVEMENT IN THE RIGHT DIRECTION, WHICH, IT IS TO HOPE, WILL BE PERMANENT. THE MODERN ARTICLE WITH STRAIGHT, STIFF FRONT IS CERTAINLY MUCH BETTER THAN ITS PREDECESSOR, WHICH HAD A PRONOUNCED CURVE IN THE MIDRIF, AND LESSENED THE WAIST BY PUSHING OUT THE ABDOMEN.

DR. J. C. MARTIN, F.R.S., PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF MELBOURNE, HAS BEEN APPOINTED DIRECTOR OF THE JENNER INSTITUTE OF PREVENTIVE MEDICINE.

STRABISMUS CONVERGENS AND ITS TREATMENT.

BY J. B. STORY, B.CH., F.R.C.S., SURGEON Oculist to His Excellency the Lord Lieutenant of Ireland, PROFESSOR OF OPHTHALMOLOGY IN THE ROYAL COLLEGE OF SURGEONS, ETC.

OUR FIRST REAL KNOWLEDGE OF THE CAUSE OR CAUSES OF THIS AFFECTION WE OWE TO DONDERS, Whose BOOK ON THE “ACCOMMODATION AND REFRACTION OF THE EYE” APPEARED IN AN ENGLISH TRANSLATION (BY OUR LATE FELLOW-TOWNSMAN) DURING THE YEARS 1864-5. DONDERS LAID DOWN THAT HYPERMETROPIA IS THE CAUSE OF CONVERGING STRABISMUS, AND ITS ACTION IS AIDED BY THE FOLLOWING CONDITIONS:—(1) CIRCUMSTANCES DIMINUISHING THE VALUE OF BINOCULAR VISION, SUCH AS DEFECTIVE SIGHT IN ONE EYE FROM ANY CAUSE; AND (2) CIRCUMSTANCES RENDERING CONVERGENCE EASIER, SUCH AS PECULIAR STRUCTURE OR INNERRATION OF THE MUSCLES, OR AN ABNORMAL MUSCULAR ACTIVITY IN THE HIGHER DEGREES OF HYPERMETROPIA.

STRABISMUS CONVERGENS IS NOT SO FREQUENT AS THE LOWER DEGREES, BECAUSE OF THE DIFFICULTY OF OBTAINING AN ACCURATELY FOCUSED IMAGE IN EITHER EYE, WHICH ALLOWS FOR THE PROBABLE IMPERFECT IMAGE OBTAINED BY BINOUCULAR FIXATION.

THIS THEORY OF DONDERS, AFTER SOME FORTY YEARS, STILL HOLDS THE FIELD, EXCEPT NOWADAYS, OF COURSE, IN TERMS SOMEWHAT DIFFERENT FROM THOSE USED BY DONDERS, BUT ESSENTIALLY THE SAME THEORY.

FOR INSTANCE, HANSEN GRUT, WHO MADE STRABISMUS THE SUBJECT OF HIS BOWMAN LECTURE TO THE OPHTHALMOLOGICAL SOCIETY IN 1890, REGARDS STRABISMUS CONVERGENS AS DUE TO AN ABNORMAL INNERRATION OF THE EYELID MUSCLES, AND A RELAXATION OF THE CONVERGING MUSCLES, OR PARALYSIS THEREOF.

HANSEN GRUT LAYS GREAT STRESS UPON HABIT, WHICH HE CONSIDERS AS UNCONSCIOUS INNERRATION, WHICH IN TIME PRODUCES A NEW FUNCTIONAL POSITION OF THE EYE.

IN INVESTIGATING THE SUBJECT OF STRABISMUS IN GENERAL, HE STARTS FROM THE ANATOMICAL POSITION OF THE EYE. THIS, HE STATES, IS DIVERGENT; FOR (1) IN REGARDING DISTANT OBJECTS, IF ONE EYE BE OCCULDED IT MUCH MORE FREQUENTLY DIVERGES THAN CONVERGES, AND IF IT REMAINS MORE FREQUENTLY PARALLEL THAN EITHER DIVERGENT OR CONVERGENT. (2) DIVERGENCE IS MORE COMMON IN DEEP SLEEP AND PROFUND NARCOSIS THAN ANY OTHER POSITION. (3) AFTER DEATH AND BEFORE RIGOR MORTIS DIVERGENCE IS THE RULE. (4) THE ORBITAL CAVITIES DIVERGE. (5) A BLIND EYE AS A RULE DIVERGES.

HE REGARDS, THEREFORE, MUCH OF THE PARALLELISM FOUND IN TESTING AS THE EXPRESS OF A FUNCTIONAL AND NOT OF AN ANATOMICAL POSITION OF REST, A PORTION OF THE CONVERGENCE, NAMELY, FROM THE DIVERGENT ANATOMICAL POSITION OF REST TO PARALLELISM, BEING LATENT, JUST AS SOME HYPERMETROPIA IS COMMONLY ALSO LATENT.

IN CONVERGENT STRABISMUS, THEN, THE HABIT OF CONVERGENCE LEADS TO THE WITHDRAWAL OF A LARGE PORTION OF THE AMPLITUDE OF CONVERGENCE FROM THE VOLUNTARY CONTROL OF THE INDIVIDUAL, OR, IN OTHER WORDS, THE CONSTANT HABIT OF CONVERGENCE DISPLACES THE FUNCTIONAL POSITION OF REST MORE AND MORE INWARDS.

AS PROOF THAT STRABISMUS CONVERGENS IS AN INNERRATION GRUT ADDUCES THE OCCASIONAL DISAPPEARANCE OF IT UNDER CHLOROFORM, AND THE CONSTANT...
parallelism or divergence observed under chloroform the moment the internal rectus is divided, while convergence returns on recovery of consciousness. No such phenomenon is observed in operating on external strabismus. He also states that after tenotomy of the internal rectus, when some convergence still is left, the secondary angle of squint becomes greater than the primary, the latter now lessened by the operation. This can only be accounted for by assuming that the strabismus is an innervation.

Other views than these are held by some ophthalmologists. According to Schweigger, the essential cause of squint is not to be found in anomalies of refraction, but in an elastic shortening of the muscles, with insufficiency of their antagonists.

Alfred Graefe also believes there is a state of passive anatomical shortening of the muscle, but he thinks this is consecutive to the squint. All these views which assume a shortening of the muscle from any anatomical condition are objected to by Hansen Grut, for the following reasons:

1. The assumed anatomical shortening has never been demonstrated.
2. It is not in accordance with the fundamental law of squinting, inasmuch as the limitation of movement of the squinting eye in the direction opposite to that of the squint is always considerably less than the angle of squint.
3. It is not in accordance with the temporary cessation of squint in narcotics, &c.
4. The spontaneous disappearance of squint renders it improbable.

In his Bowman Lecture on the "Etiology and Educative Treatment of Convergent Strabismus" Professor H. H., who takes up the same position as Hansen Grut. His conclusions are:

1. That strabismus convergens is a disease of innervation, the visual centres failing to control the act of convergence, which consequently becomes degraded or purposeless; the act is excessive because uncontrolled.
2. Failure of control depends on faulty development of visual apparatus, peripheral or central.
3. Hypermetrophia predisposes.
4. The disorder is confirmed by suppression of retinal impressions in squinting eye.

The one essential cause of squint, then, is a defective development of the fusion faculty, and when the fusion faculty binocular vision is impossible.

The faculty of binocular vision may exist without being perfect. There are found, according to Worth, three different grades of the faculty existent. (1) Simultaneous macular perception. (2) True fusion with some amplitude. (3) The sense of protective. It is generally allowed that the power of fusion is not congenital, but is a function acquired after birth by experience. The ocular movements of the new-born infant cannot be described as anything else than purposeless, and even the power of macular perception is probably imperfectly developed at birth.

It is only by use (the habit of Hansen Grut) that the child develops the functions of its retina and its central visual apparatus, with the various centres connected with the eyes both sensory and motor. At birth the visual apparatus, both peripheral and central, is even anatomically an imperfect structure. Very probably, of the various ocular functions that of fusion is the last to be fully developed. According to Worth its full development is reached normally before the end of the sixth year of life.

Before adopting treatment of any kind, the following points should be accurately noted:

1. The kind of strabismus.
2. Unilateral or alternating.
3. Continuous or periodic, and, if continuous, whether constant in amount or varying.
4. Duration and mode of onset.
5. Physical condition of each eye.
6. Functional condition of each eye, viz., vision, field of vision, refraction, fixation power of crooked eye, binocular vision; &c., if diplopia exists, or is to be elicited by means, coloured plates of fusion tubes, &c., determine the suppression area.
7. Degree of strabismus, by which I mean the angular measurement of the deviation, for no approximation to accuracy can be made by linear measurement. There are several methods of measuring the angle of squint, subjectively by conservation of double images when this is possible, or objectively by the arc of the perimeter, or by Wecker and Masselet's "keratoscope," or by the simple tape measure proposed by Priestley Smith. The latter method can only apply when the primary and secondary angles of squint are equal in amount, but as this is substantially true of the ordinary cases of convergent strabismus, the method for practical purposes is sufficiently accurate. For perfect accuracy in all methods of objective measurement the value of the angle +, or rather of the angle γ, or better still, should be ascertained. The angle should be determined for near objects as well as for objects at a distance, which require parallelism of the visual lines.
8. The power of the muscles, viz., their lateral excursions, should be noted, also by angular measurement,
9. The possible excursions of the punctum proximum of convergence. (Knapp lays down that after an operation for convergent strabismus the punctum proximum of convergence should not be further from the nearer than 5 cm., otherwise divergence may arise later.

As strabismus convergens is an affection of early childhood, and as the younger the child is when brought for treatment the better the ultimate result, it is probable that many of the patients will be too young to admit of examination into all these points. We must be content to determine as many of them as the age and intelligence of the patient allows.

The measures adopted for the cure of strabismus, are of three kinds. (1) Optical; viz., correcting whatever errors of refraction exist. (2) Operative, either tenotomy or advancement of the insertion of a tendon, or both combined, or tenectomy, or folding of a tendon itself, or partial tenotomy, or advancement or division of the capsule of Teneon. (3) Orthoptic or, as Priestley Smith prefers to term it, educative.

There is no need to dwell on the optical treatment. No rational man neglects to correct any anomalies of refraction present in cases of squint.

(2) Operations, in my opinion, should only be undertaken when optical and educative treat-
ment has failed, and the decision upon this point must be left to the discretion of the medical man in charge of the case. Great difference of opinion exists among ophthalmic surgeons as to what operations should be done in strabismus cases, whether one or both eyes should be operated on, and whether advancement should be the rule or the exception; and also as to what particular method of "advancement" should be performed. There is so much to be said on these points that I shall not attempt to enter upon the arguments in support of the various opinions, as it would unduly lengthen this communication.

From what has been stated, it is evident that as the cause of strabismus convergens is a defective fusion faculty the cure of strabismus must consist in establishing or re-establishing a fusion faculty. Without this faculty a permanent cure cannot be guaranteed, but the eyes will sooner or later assume their anatomical or functional position of rest. The earlier the treatment is begun the better. No infant is too young to be treated, and it is only in the first years of life that we can expect to develop the fusion faculty. If children are left untreated—it is not uncommon till they are past the age of eleven years—it is difficult to recover, and the squint cannot be depended upon.

If the deviating eye has not the power of fixation, i.e., central fixation, our first effort must be directed to this point, and we must endeavour to make the child use this eye to the exclusion of the other. This we do by covering the straight eye for a certain period of the day for as long a time as possible, so that the child has to pay attention to the visual sensations of the defective eye. In children whose power of fixation is absent at the first visit, it will often be found that the power is present after this treatment has been adopted for some weeks. The treatment can be assisted by instilling atropine into the straight eye, to lessen the optical value of that eye and thereby increase, if possible, the value of the crooked eye. In cases where there is good fixation in the crooked eye we often have the satisfaction of being told after some time that the bad eye is straight, but that the cast has gone into the good eye. This is a proof that good vision can be obtained in the squinting eye. Occasionally, we find that atropine in the good eye cures the squint at once, and the cure is usually then permanent if correcting glasses are fitted before the mydriasis has passed off.

If a cure has not been obtained by the above measures, atropine should be put into both eyes, and correcting glasses ordered. The glasses should be worn constantly, and, if necessary, the atropine should be continued for months before recourse is had to operative measures, and meanwhile the power of binocular vision should be developed by stereoscopic exercises. The great difficulty in these exercises is the habit of suppression of the vision of the squinting eye. This may be got over by making the illumination of the room so weak that the eye not intently than that shown to the other eye. We can usually effect this by some little adjustment in any stereoscope, but what is probably the most perfect instrument for educative treatment is the amblyoscope of Worth. It is, however, not an instrument which can be given to patients for home use, and I have no personal experience of it.

The next difficulty is that the angle of deviation is usually so great that no ordinary stereoscope brings the images anywhere near the two maculae. This is overcome by stereoscopes such as Hallwach's, which can be set at any angle from 0° to 50°. It is the best stereoscope that I am acquainted with for this purpose, but its cost is so great that it is within the means of the majority of those who would take the trouble to employ it.—12s. 6d.

The fusion tubes of Priestley Smith, and the heteroscope of the same author, have not very great educative value, but are most useful for ascertaining if simultaneous macular perception is present. When we have found by means of the latter instrument what angle is necessary, we try to elicit fusion of some of the pictures made for that purpose in Hallwach's stereoscope.

As a sample of "orthoptic" treatment, I may cite the case of Miss E. L., æt. 4, who came to me in April, 1902, with history of convergent strabismus of right eye for one year. Angle, 14 degrees, convergent. Large letters can be made out. Left V. ; right, H. 5; left, H. 3, by erect image. Atropine for four days brought the eyes nearly straight, and she was ordered to use the drops every second day. Three weeks later the squint had returned, and I tried atropine in the left (good) eye only every second day, and had this good eye bandaged for some time every day, so as to force the crooked eye to act. After one month of this treatment the eyes were perfectly straight, and the child could fix well with the right eye, and see with it, but imperfectly, and I observed that she projected towards the temporal side. Atropine was constantly used in the left eye till October, the eyes remaining straight all the time, though I observed that on fixing very near objects the left (good) eye tended to converge. The bandage, too, was used daily. Vision of right rose to 6/6, that of the left being the same as before (under atropine). In October I ordered + 5 right, and +4 D left, and gave up the atropine. Six weeks later the eyes were straight, with 6/6 and without mydriatic. In May, 1903, eyes were still straight with the glasses, and fusion with heteroscope from parallelism to 15 degrees convergence.

By stereoscope excellent simultaneous macular perception, but no definite sense of perspective. Stereoscopic exercises are to be used at home, and I expect in this case to develop full binocular vision.

Case II.—Miss E. J., æt. 34, seen in October, 1902, with left internal periodic strabismus of one year's duration. Angle about 16° H. 2 D or 3. Atropine in good eye resulted in a temporary cure, and good fixation was obtained in the left eye. After atropine was abandoned the squint returned, the right eye now being periodic. Fusion with heteroscope from parallelism to 15° convergence, but with excentric not central fixation. Atropine in both eyes now put them quite straight, and simultaneous macular perception was proved to exist. The case is still under observation, and I expect a perfect cure.

Miss A. A., æt. 11, in 1901. An alternating convergent squint of 18° with good vision in both eyes. I had seen this child some five years before, but have lost my notes. Glasses to correct her hypermetropia (of only 3 D) cured the
THE TREATMENT OF RABIES
BY THE
METHOD OF HOYGES:
STATISTICS OF THE INSTITUTE OF
ALPHONSSUS XIII. (a)

By Drs. MURILLO and J. LEAVADOR,
of Madrid.

The labours of many students of bacteriology are
begging to throw some light, even though it be a
flickering and not brilliant one, on the question of
rabies. And in proportion to the increase of our
knowledge of the disease, so increases our affection for
the marvellous intuition of Pasteur, whose colossal per-
sonality stands out separate from and overshadowing
his contemporaries. His scientific fellow-workers were
too near to him to form a true estimate of his works;
to them the picture he drew appeared confused and
indistinct; but when viewed at a proper distance, the
charms by its beauty and perfection. The scientific
world in 1885 looked on Pasteur's theories as containing
absurd, daring, and unpardonable therapeutic sugges-
tions—theses that to-day are—considered to express
great truths of permanent value, theories that have created
general admiration for their boldness and originality.
In his studies, Pasteur followed the path
that led to success in the discovery of the value
of inoculation against cholera in fowl, and caruncle
and erysipelas in pigs. Knowing that the inoculation
of attenuated virus immunised against natural virus, he
set himself to devise some method by which he could
obtain a sufficient quantity of a standardised virulent
virus. Quickly he found by experiment that it was possible to
increase the potency of the natural virus to its most
lethal power by a series of injections practised un-
interruptedly on rabbits. He thus obtained the toxin
of maximum lethal power—his highest standard.
In like manner he found that by drying the spinal cords
of rabbits that died of rabies and injecting this from
monkey to monkey, he could lessen the toxic effect of
the virus until it disappeared. This greatly attenuated
toxin, or virus, was his zero point of stan-
dardisation. When he procured his toxin he divided
it into doses, which he preserved from change by keep-
ing them in hermetically-sealed glass tubes. The
virus of maximum intensity was that which killed in
seven days, and the virus of least intensity which he
used did not kill before twenty days. In this graduated
scale of virulence he had ready to hand a toxin from
the weakest to the most active, by which, commencing
with the less toxic and gradually going to that of
the greatest toxicity, he, by hypodermic injections,
confided immunity on the human being from rabies.
Such is the method of Pasteur, admirable in its
precision and thought, a system for immunisation against a disease of the nature
of which we were completely in the dark—a dis-
ease of which he knew not the cause, neither did he ever
know the real nature of it. Two things guided him in his studies, both of which
were intimately bound together. First, the fact that the nervous system is markedly the site, indeed, almost
exclusively so, of the pathological lesion of rabies;
and second, the observation that subdural, intra-cranial inoculations produced the disease at will, and of a typical and con-
stant character. Pasteur thus found that whatever
was the source of the disease he had succeeded in cul-
tivating and controlling it. Under his hands its viru-
lence was strong or weak. He exalted or attenuated
at pleasure the pathogenic power of the bacteria. He
and Hoyges now determined that whatever cause
produced by attenuation was one degree, not of
quality; the properties of the micro-organisms were
unchanged, their numbers were lessened, that is to
say, the lethal serum represents the maximum amount
of the pathogenic material in a defined space, and
desecration of the spinal cord of the rabbit does no
more than lessen the quantity of the pathogenic sub-
stance in the given volume without changing its viru-
lence. Thus, a spinal cord, dissected for a period of
five, to twenty days, loses successively increasing quan-
tities of its virulent power. The same effect may be
produced by the gradual prolongation of the period
of incubation in the animals submitted to experi-
mentation, corresponding to the effect produced by
increasing the time of drying the spinal cords, which,
on the fourteenth day, are found to have lost all their
toxic properties, and if injected into the cerebral
meninges produce no effect, not even an unpleasant
symptom. The attenuated virus, the product of a
long incubation period, is found to have no toxic prop-
erties, and in proportion to the period of incubation
so is the toxic power of the virus. So also is the
virulence restored by subdural inoculation; cranial
injections in the rabbit until the lethal proper-
ties of the virus attain a power of causing death in
seven days. This attenuation from the mildest form
of the toxin to the most fatal is considered by Hoyges
as an evidence of how readily the poison of hydro-
phobia may be produced. Given a quantity of
attenuated toxin, by progressive diminution or increased
by graduated series, it should produce its effects in
seven or twenty days in proportion to its toxic strength; this result is obtained as well by graduated
incubation periods as by the attenuation or exaltation
process. The facts that poisons introduced into the
nervous system have a definite period of incubation,
on the expiration of which the earliest symptoms com-
mence to show themselves, and that identical toxins vary in their intensity in different individuals, show
how much the individual reacts on the toxin. Where
the incubation period is long in natural rabies we used
a sufficiently long interval in which to introduce the
anti-rabitic virus and to immunise the patient. R.
Krauss and B. Kreissel have established the fact that
(1) in normal serum no rabitic matter exists; (2) that
the substances are found on the twentieth or twenty-
second day of the treatment; and (3) that in some
individuals neither before nor after do anti-rabitic
bodies appear in the blood.
To make the steps of the development of the disease
more intelligible we give the classification of its stages
according to Hoyges: (1) The migratory period,
which extends from the time on which the patient was
bitten to the infection of the nervous system; (2) the
incubation period, which extends from the time of the
infection of the nerves centres to the first manifesta-
tion of symptoms of the disease; and (3) the terminal
period, from the appearance of paralysis until death.
The modifying influence of the individual on the rabitic
poison offers an explanation of some of the many
anomalous cases which occur. In some we find the
animal refractory to immunisation, in others there is
extreme susceptibility to the poison, and the immu-
nity is produced between the fourteenth and
twentieth day—the extreme limit of time for the
manifestation of symptoms in the human being. And,
finally, in the analogy between the rabitic virus and
the virus used for other morbid states we see sound
reasons for producing immunisation gently and gra-
dually, lest serious results might follow. Careful con-
sideration of the micro-organisms of these toxin bodies
clearly shows that they must be used with that
measuring stick, more so than we are in the habit of bestow-
ing on other remedies. These difficulties in the prac-
tical use of anti-rabitic toxin make it all the more
acceptable to us that Sehor Cajal has determined to
publish a department of the Institute of Alphonsus
XIII, for the treatment of rabies by the method of
Hoyges, which is based on the attenuation of the
rabitic serum by dilution. Hoyges' method has the
advantage over that of Pasteur of simplicity and

(a) A Paper read before the In erational Medical Congress at
Madrid.
accuracy. It is sufficient to say, in illustration of the
simplicity of the method, that by care, fourteen spinal
cords of rabbits can be dried at an equal temperature,
and an equal extent. To obtain standardised virus,
one or two rabbits were trepanned daily, and fresh
spinal cords obtained, which he weighed with accuracy.
From these he produced the mother liquor used in the
preparation, which he dissolved without otherwise than
the precautions necessary to ensure asepsis. Although
the rabbits bought for experimentation are full grown,
they are far from being of the same weight, and their
spinal cords differ in weight and thickness. This
difference necessitates the cord being exposed for a
greater or lesser time, according to its size, lest the
thinner spinal cords in drying should become more
desiccated than those which were thicker and so have
their virus too much attenuated. A thick cord would
be less attenuated in fourteen days than a thin one
in ten days. The dilutions are made by weight and
measure, and the attenuations obtained are mathe-
matically correct. By this method a regular supply of
the virus is provided, and it can be produced in great
or lesser quantities as the demand warrants. The care
with which asepsis is secured is shown by the fact that
in many thousands of cases of the hypodermic injection
we have not had a single case of abscess.
We submit to the judgment of our medical brethren
the statistics of the first hundred cases treated in the
anti-rabid department of the Institute of Alphonse
XIII. The statistics show 102 cases, but two of these
patients were suffering from symptoms of the disease
left Madrid soon after their treatment commenced.
Three months after they left we received
news from the local authorities that the patient had
made a good recovery. Of the remaining 100 cases,
we had at a subsequent examination 87 patients
in his first series of cases, he had a mortality of about
100, and
in his second series of a hundred had a mortality of
0.59 a 100. We adopted Pasteur’s classification of our
patients: (1) Patients bitten by animals demonstrated
by the inoculation test to have rabbits. (2) Patients
bitten by animals which the veterinarian certified from
examination of the lesions to have rabbits. (3) Patients
bitten by animals which were supposed to have rabbits.
Of the first group we had 41 patients, of whom 12
were bitten by dogs; in the second group 21 patients,
of whom 17 were so bitten: and in the third group
41 patients, of whom 14 were bitten in the
same way.

TOTTENHAM HOSPITAL.

CARES FROM THE DERMATOLOGICAL CLINIC UNDER
THE CARE OF G. NORMAN MEACHEN, M.D., M.R.C.P.
LOND. AND EDIN.

1. Pruritus Associated with High Arterial Tension.—
A female patient, 55 years of age, gave a history of
blemish on the skin which had been present for the last three
months. She also suffered from cramps in the legs,
dizziness on rising in the morning, and “rheumatic pain” in the limbs. She was said to have had gout
twenty years ago. There was little to see upon the
surface of the skin except a few scratch-marks, and parasitic causes were excluded. The skin of the hands
and forearms was coarse and rough, a soil favourable for
the development of eczema. The patient was of
woman.
The urine contained a trace of albumin and
was of 1022 sp. gr. The pulse-tension was slightly
but distinctly raised. The tongue was furred and the
hollows costive.

Dr. Meachen remarked that a generalised pruritus
was frequently an early symptom of granular kidney,
and might be associated with other signs met with in
the preliminary stages of the complaint, such as cramps
in the legs, head-ache and sickness. Very often, too,
some form of eczema of a chronic type, what some
clinicians would term “gouty,” was also present, and,
indeed, this variety of pruritus was specially seen in
those of the gouty diathesis. As regards the pathology
of the condition, the toxic theory had been put
forward which supposed that the minute nerve-ends
in the skin were irritated by toxic materials
circulating in the neighbouring capillaries, thus giving
rise to the sensation of itching. Whether this was so
or not, there could be no doubt that the pruritus in
such individuals was materially relieved by the ex-
hibition of remedies which assisted in restoring the
impaired renal excretion and in removing toxic waste-
products from the large intestines.
The patient was therefore ordered a diuretic, alkaline
and aperient saline mixture thrice daily, and was
advised to be abstemious in regard to meat and stimu-
lants. At the same time an alkaline lotion containing
15 gr. of calamine to the ounce was prescribed for local
application.

2. Pityriasis Versicolor in a Child, at. II.—The
patient, a girl, had been suffering from a relapsing
eruption on the body for a few weeks. At its first
appearance it was said to have been mistaken for
rothelms. When seen, the rash consisted of an aggre-
gation of small patches and spots of a pale reddish-
brown colour situated on the chest, axilae, shoulders,
and the back, extending well up into the neck behind.
Part of it was coalescent, and the surface slightly scaly.
The child complained of no itching whatever.

Dr. Meachen said that at first sight the diagnosis of
seborrhoeic dermatitis might be considered, but again
this was the absence of any inflammatory
manifestations. Pityriasis rosea was negatived on
account of the length of history and the distribution
of the eruption. The fact that the child said it did
not itch was doubtless due to the child’s young age,
and that the rash was not considered by the child
at all. A surface-scratching of the patches examined
in liquor potassa under the microscope revealed the
presence of the microsporon furfur in abundance. It
was such a rash as was frequently met with in
children, but nevertheless such cases often occurred.
The mother was directed to wash the skin with ordinary
soap and immediately afterwards to apply a lotion of
4 dr. of sod. hyposulphitate to the ounce of water every
morning. An ointment containing sulphur, acid
salicylic, as 4 4 dr., and 10 gr. of hydrarg. ammon.
to the ounce of vaseline was also ordered to be rubbed
in at night-time. As the child was wearing flannel
next the skin, this was recommended to be changed and
disinfected.

The lesions had wholly disappeared at the end of
three weeks’ treatment.

Transactions of Societies.

SOCIETY FOR THE STUDY OF DISEASE IN
CHILDREN.

MEETING HELD AT THE ALEXANDRA HOSPITAL FOR
SICK CHILDREN, BRIGHTON, JUNE 20TH, 1903.

DR. WAYLAND CRAFF EY in the Chair.

MR. H. A. TUBBY read a paper entitled
THE TREATMENT OF SURGICAL TUBERCULOSIS IN URBAN
HOSPITALS JUSTIFIABLE?
in which he argued from statistics that such cases
ought to be treated in special institutions in the
country or at the seaside.

MR. CLEMENT LUCAS pointed out the reasons for the
failure of cases treated in London hospitals was not
chiefly owing to the want of sufficiently pure air in
such hospitals, but rather to the fact that such were
more apt to return to their unhealthy habits.

Dr. SANSOM also spoke, and expressed his approval
of Mr. Tubby’s suggestion.

Mr. CLINTON DEMP found the matter of great
importance, and suggested that a subcommittee should
be formed to consider the question; and Mr. Jaffray seconded the proposal.

Mr. Dent, Dr. Dawson Williams, Mr. Jaffray, Mr. Sydney Stephenson and Mr. Tubby were appointed members of the subcommittee.

Mr. Clement Lucas then read a paper describing the removal of a tin mouth-organ from the small intestine of a child, at 1. The situation of the metal body had been localised by skigrams, but the exact situation was not so easily determined as in another case which had been brought by Mr. Lucas before the Society, where a large nail was in the second part of the duodenum. In this case the metal body was in the jejunum.

Mr. Clinton Dent referred to a case where a metal body almost precisely similar to that mentioned by Mr. Lucas had been swallowed. Its movements from place to place within the abdomen had been watched for some time by means of skigraphy, but, curiously enough, at the time of a laparotomy it could not be found, and, although never seen in the stools, must have been passed per rectum.

Dr. Edmund Hobhouse then read a paper upon the

FUNCTIONS OF CHILDREN'S HOSPITALS.

One of the most important parts of the duty of a physician for children's diseases he thought to be the education of the mothers and of the public upon health questions affecting children.

Mr. R. H. Parry read a paper in which he described an

OPERATION FOR THE REMOVAL OF TUBERCULOUS GLANDS

from the anterior and posterior triangles of the neck by means of an incision through the hairy scalp. Photographs of children before and after operation were shown. The operation, he said, was not nearly so difficult as might be thought probable, and drainage was perfect.

Mr. Morgan thought that cases must be seen early to be successful if treated by Mr. Parry's method.

Mr. Clement Lucas also thought that, although useful in some cases, the operation could not be generally applied.

Mr. Tubby also considered that the operation introduced an element of danger.

Mr. Parry, in reply, said that he did not think the dangers great. In 20 operations he had twice cut the carotid, but it was easily ligationed.

Dr. George Carpenter then read a paper upon

SYPHILITIC NEPHRITIS IN AN INFANT.

Dr. George Sutherland said the subject was of great interest, but that he did not consider this case so conclusive as some which had been brought before the Society.

Mr. Carmichael commented upon the excellence of the drawings which accompanied the paper.

Dr. Carpenter also read a paper upon an analysis of several hundred cases of

Splenomegaly in Children.

In only a small percentage syphilis and rickets could both be excluded.

Other papers were by—Dr. Edmund Cantley, upon a case of "primary pneumococctic meningitis" in a child, when diplococci had been obtained from cerebrospinal fluid obtained by lumbar puncture; by Dr. Alexander Morison, on "Optum in the treatment of children"; by Dr. Theodore Fisher, on "Dilatation of the bronchial tubes after measles"; by Dr. Eldon Pratt, on a case of "cerebral tumour," in which temporary recovery took place; and by Mr. Sydney Stephenson, on "A common appearance of the optic papilla likely to be mistaken for optic papillitis." Beautiful drawings of the condition were shown.

In the evening the members of the Society dined at the Grand Hotel, and the following day were entertained at lunch by Dr. Wayland Chaffey at the Hôtel Métropole.

Special Articles.

BRITISH SANATORIA FOR CONSUMPTION.—II.

BY OUR SPECIAL MEDICAL COMMISSIONER.

THE VICTORIA HOSPITAL FOR CONSUMPTION.

CRAIGLEITH, EDINBURGH.

The Edinburgh Victoria Hospital may deservedly receive the first place in a study of British Sanatoria for Consumption, since it was the first institution in the United Kingdom to offer gratuitous treatment to the phthisical poor strictly in accordance with hygienic methods. Its establishment in 1894 and advance during the last thirteen years are due in great measure to the pioneer work of Dr. R. W. Philip. It is essentially a national institution, and is still the only absolutely free sanatorium for consumptives in Scotland. It is well situated in a finely wooded park within two miles of the centre of Edinburgh, and only a few minutes' walk beyond the tram terminus. An old mansion house, which has been well adapted, forms the original building, but many improvements and additions have been made, and the place has just undergone extensive renovation. The house faces due south, and the rooms are conveniently arranged. Heating is provided for by open fireplaces, but during recent years no attempt has been made to maintain a uniform temperature indoors. It has been found that the best results are obtained when the indoor conditions are allowed to approximate to those of the open.

An excellent annexe close to the original building provides for eight patients, and was built and furnished for less than £800.

Specially noteworthy are the very excellent but simple and cheap shelters which are arranged round the lawn, and in which the male patients live. The general character of these shelters is indicated in the accompanying figure.

FIG. 1.—THE SHELTERS (a fete on the lawn).

An important scheme for extension is now being proceeded with. Three admirably designed annexes are already in course of construction, and together will accommodate an additional 32 patients. Each unit is self-contained, and has been planned so as to ensure a maximum of sunlight and abundant fresh air. An annexe containing eight beds costs approximately £1,000, and there's every reason to believe that these simple but admirably constructed buildings will prove particularly suitable for their purpose.

The laundry, laboratory and other offices are well placed, and everywhere there are abundant evidences of efficiency, economy and experience. The gardens and grounds are peculiarly attractive.

Many features of interest are noted. The institution admirably indicates the educational and other advantages which come from close touch with
the life of a busy city. Every day a number of "day-boarders" come to the grounds and are fed and drilled in hygienic procedures, returning to their own homes for the night. This is undoubtedly an excellent means for mitigating the difficulty which now arises everywhere from the insufficiency of sanatoria for the poor, and may be commended to the consideration of hospital authorities in different parts of the country.

FIG. 2.—Block Plan of Extension of Victoria Hospital.

A rather exceptional and somewhat startling arrangement allows association during the day of the sexes in the grounds, always, of course, under supervision, and, it is claimed, without any serious disadvantages.

Many of the patients practise some simple form of respiratory exercise, with the object of improving respiratory action and chest capacity.

The experience of the Victoria Hospital seems to conclusively prove that phthisis can be treated with success in a climate which, at least during a considerable portion of the year, cannot be reckoned as particularly congenial. Dr. Philip holds, and certainly there are good grounds for such a view, that the tuberculous patient, of whatever country or race, can be suitably treated not far from his own home, and certainly Edinburgh experience supports such a contention.

As with other institutions for consumption difficulty is often experienced from the fact that in many instances help is only sought when the disease has reached an advanced stage. To obtain satisfactory results it has been found necessary to lengthen the limit of residence, and some patients have been kept under treatment for six months.

It is interesting to find that some old patients have been retained in the service of the hospital.

In connection with the hospital there is an outpatient department, which is situated in the heart of Edinburgh, and affords a central office where patients are received and treated, and suitable cases selected for open-air treatment. The educational value of such effort cannot be over-estimated, and it is but just to remember that Dr. Philip has been quietly carrying on this work for many years, and long before Calmette and others advocated the establishment of the now much-lauded "anti-tuberculous" dispensaries.

A specially commendable feature is the provision whereby bed-ridden patients and those who through weakness or other disability cannot attend as outpatients, are visited as home patients by an out-door medical officer, whose services must prove invaluable not merely in relieving suffering, but in teaching patients and friends how best to lessen the risks of propagating the disease.

The honorary physicians are Dr. R. W. Philip and Dr. G. L. Gulland, and Mr. David Wallace is the honorary surgeon. Miss Guy is the Lady Superintendent.

An excellent report of the work of the institution is published annually.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, July 5th, 1903.

TREATMENT OF CANCER BY THE X-RAYS.

At the last meeting of the Academie de Médecine, Professor Cornil read a paper on a case of carcinoma of the breast treated by the Röntgen rays and quinine. The patient consulted him for a tumour of seven years' standing which had all the appearance of cancer. Having refused an operation, she was treated at first with quinine, and a few months after the tumour had ulcerated recourse was had to the X-rays, quinine being continued. The sore healed up rapidly, but reopened; finally healthy granulation set up and at present the cicatrix is almost complete and the patient apparently cured.

PREVENTIVE TREATMENT OF ARTERIO-SCEROSIS.

Professor Huchard passed in review the preventive treatment of arterio-sclerosis. Among the principal hygienic measures, M. Huchard recommended a lactovegetarian régime, massage, muscle exercises, and balneation. As to drugs, he considered that iodides should be reserved rather for confirmed sclerosis. In the pre-sclerosis phase it was better to prescribe vasodilator agents such as nitrite of amyl, trinitrin, nitrite of soda, and organo-therapy. In diminishing the peripheral resistance those agents facilitated and increased the energy of the central organ of circulation.

TREATMENT OF DYSENTERY.

The treatment of true dysentery (mucus and blood in the excreta) by enemas of permanganate of potash is highly recommended by M. Gastineau. The strength varies between five to fifteen grains for a quart of warm water. In several cases in which he tried this
agent the results were very satisfactory and almost immediate. In some cases he gave the permanganate by the mouth in one to three grains daily.

**Adrenalin.**

The numerous advantages and applications of adrenalin as the most powerful hemostatic we possess should not mask the fact that this curious alkaloid discovered by Takamine must be handled with care, for grave cases of poisoning have been reported from time to time. Dr. Roussel employs the remedy in varied cases, hemoptysis, hematemesis, cerebral hemorrhages, &c., without experiencing any accident. The dose he employs is from six to twelve drops daily of the solution, it being two or three drops in one case. In one case he had serious trouble. A woman suffering from hemorrhagic metritis, for which she had previously undergone several minor operations, including curettage, sent for him as the hemorrhage had returned. Brining into view the os by means of the speculum, M. Roussel painted it with a few drops of adrenalin solution, and gave by the mouth five drops during the day. Twenty-four hours after the patient complained of vertigo, and experienced great cardiac pain, while the rhythm of the heart was irregular. In the night, however, after three or four hours' sleep, the symptoms passed away and the adrenalin was not continued.

Similar cases wherein the substance in question was the exciting cause have been reported by Souques and Morel, and also from Germany.

**Arterio-Sclerosis, Headache, Noises in the Ears, Creeping Sensation in the Limbs, Insomnia, &c.**

Chloride of sodium, \( \text{NaCl} \).

Sulphate of soda, \( \text{Na}_2\text{SO}_4 \).

Phosphate of lime \( \text{Ca}_3\text{(PO}_4\text{)}_2 \).

Phosphate of magnesia \( \text{Mg}_3\text{(PO}_4\text{)}_2 \).

Carbonate of soda \( \text{Na}_2\text{CO}_3 \).

Dissolve the above in water, add to the mixture half a teaspoonful of saline laxative, such as CHAMOMILE, and divide into twelve wafers, one to three daily according to tolerance.

---

**Germany.**

[FROM OUR OWN CORRESPONDENT.]

**Berlin, July 4th, 1903.**

**TRENDELENBURG'S Position and its Dangers.**

At the meeting of the German Society for Surgery, Hr. Kraské continued his address on this subject. He said that the symptoms of hæmatemesis in the second case brought to mind the observation of v. Eiselsberg on hæmorrhage from the stomach after operation for hæmorrhage. Here there was a disturbance in the region of the superior mesenteric. Possibly the high position in fat subjects led to disturbance associated with hæmorrhage. Had v. Eiselsberg made use of the high position in these cases? The speaker summed up in conclusion: (1) The high pelvic position might under certain circumstances, in cases with degeneration of the heart and great vessels, be dangerous; (2) in very fat people the position might lead to displacement of intestine after closure of the wound, and so to stasis in the portal system and hæmorrhages. The position, therefore, in such people should be maintained as short a time as possible, the dressings should be applied whilst the patient was in the horizontal position, after the operator had satisfied himself that there was no displacement. At the same time the position was invaluable in pelvic and abdominal operations.

Hr. Trendelenburg, Leipsic, declared himself in agreement with Kraské. But the dangers described threatened only in very special cases. In patients with large diseased vessels it was better to abstain from putting them into the position. He had never seen a case of ileus, but it might occur in very fat-bodied people. In such individuals the intra-abdominal pressure in the high pelvic position was not negative, and for this reason he did not use it. In fat people the position should not be made use of. The operation table should be so constructed that the horizontal position could be reverted to at any moment. He himself never kept the patient long at a time in the high position—only from five to ten minutes—but he returned to it on and off if necessary from time to time.

Hr. v. Eiselsberg, Vienna, had made use of the position very extensively, and was highly pleased with it. Only in one case did a fat person die apoplexy occur, which was due to the position. In his cases of hemorrhage after herniotomy the position had only been made use of once.

Hr. König, Berlin, said that the position in regard to abdominal abscess had not been discussed. If he had found an abscess in the abdomen it was contra-indication for the position—it should be at once given up. In this way he had pulled through with a large number of cases, so that in all probability would otherwise have been lost.

Hr. Lavenstein, Hamburg, laid stress on the construction of the table. He used one of his own devising, in which the horizontal position could be resumed at once. He did not close the wound until after the horizontal had been returned. He once had a case of ileus of the sigmoid flexure after removal of a pelvic tumour, but it was doubtful whether the high position was the cause.

Hr. TRENDELENBURG observed that vomiting might occur in any position. The high position did not favour the aspiration of food into the trachea; on the contrary, he preferred it when there was any tendency to vomiting.

Hr. Heidenhain, Worms, had seen volvulus after total extirpation of the uterus, when the high position had not been employed. When it was used the head should not be allowed to hang straight down. He had the head-board placed almost horizontal; in that way blood stasis in the head was avoided.

Hr. Rotten, Berlin, had had a fatal case from aspiration of food into the trachea in a case of operation for diverticulum of the oesophagus, in which the high position was adopted.

Hr. Kümmell, Hamburg, had used the high position in many hundreds of cases without any accident. He allowed the patient to lie almost inverted. In approaching asphyxia he preferred the horizontal; atony of the bowel might come on after abdominal operation in any position.

Hr. Dührssen, Berlin, had seen only one death in the high position; it was from cerebral hæmorrhage, and the patient was a fat woman. The position should therefore be avoided in such people. He had also observed vomiting; this could be avoided by previous washing out of the stomach. Before closing the wound the horizontal should be restored.

At the Medical Society, Hr. Doenitz gave a short account of the recent unfortunate case of

**Plague,** to which a young medical man fell a victim. It was probable that Dr. Sachs, the unfortunate investigator, had aspirated some juice from the gland of an infected guinea-pig, that some air had also entered the syringe, and that in emptying the syringe on an agar plate some of the material had spurted and infected him in the mouth or fauces. Then plague pneumonia developed secondarily. It was remarkable that the first symptoms of the disease appeared five days after the deceased had last worked with plague material. What
possibly favoured the onset of infection was that he had worked too hard and neglected his food, and the autopsy showed that he had an old tuberculous patch in the apex of one lung.

For preventing the spread of the disease, the patient was at once isolated, as well as all who had been in contact with him, and all had anti-plague serum injection. Thanks to these precautions, only one person took the disease, and that in a remarkably mild form, apparently in consequence of the serum injection. He had been then quite well for some days.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, July 6th, 1903.

CHRONIC NEPHRITIS OR HEMATURIA.

Schuller showed to the Gesellschaft a patient of his who had been operated on for dangerous haemorrhage from the right kidney. After the nephrotomy, it proved to be a case of chronic nephritis, but, strange to relate, the haemorrhage immediately ceased after the operation.

In the urine no casts could be found, and all the known means employed to confirm the clinical diagnosis of simple persistent haemorrhage from the kidneys. No more albumin could be calculated than that present in the blood.

Teleky asked if any explanation could be given for this negative condition after the operation.

Schuller said that none could be offered, as the elimination of albumin was still very low for an inflammation of the kidneys.

ANEURYSM OF THE AORTA.

Pauli next brought forward a patient suffering from aneurysm of the aorta ascendens as well as the right carotis communis. If one hand is placed over the aneurysm on the right side of the neck, while the other is laid over the left, the latter, though synchronous with the right, will be found to retract rather than expand. This, he thought, was due to the large sac yielding more easily than the walls of the vessels and easily admitting the flow of blood.

OSTEOID CHONDROMA.

Lorenz interested the Gesellschaft by showing them a large osteo-chondromata which he had removed from a patient. The tumour was diagnosed twenty-two years ago by Professor Billroth, who, on account of its great softness, diagnosed it as a soft sarcoma. Three years after this the whole character of the growth changed and became rigidly hard, lying deep in the pelvis opposite the ischial bone. Recently the swelling became so large that the patient was unable to follow his work. In October last the tumour began to ulcerate and necrose, necessitating operation owing to peritonitis having set in from lymphatic poisoning.

TUBERCLOSIS OF THE ANKLE-JOINT.

Daminos presented three patients on whom he had operated for tubercle in the ankle-joint. After exteriorizing the talius he filled the cavity with Mosetiog's bone dressing with the best results. He related the history of thirteen other cases on whom he had operated in a similar manner with only one and a half centimetres shortening of the leg. The filling seems to induce a healthy condition and act as a support for the soft coverings, which do not shrink, and by the presence of this foreign body a neararthrosis is produced leaving excellent movability in the joint.

Eiselberg said that his results were equally good, and confirmed the use of the "plombe" as an excellent adjunct in surgery.

ACUTE INFLAMMATION OF THE MIDDLE EAR.

Kaufman gave the history of a female, aged 45, who after three weeks' acute inflammation of the middle ear was attacked with an abscess in the temporal lobe of the brain. After undertaking the operation, it was found that no connection existed between the ear and the abscess, as the bone and the dura mater were found perfectly healthy, but pus was present in the middle ear. He pointed out that many other cases of this nature existed and ought to guide us in our diagnosis. He especially recorded two other cases of abscess in the brain. The first was a boy, aged 15, who died with symptoms of meningitis, on whom he had previously operated for an abscess in the temporal lobe. At the operation another abscess was found in the cerebellum which had been the cause of the fatal mischief. The second was a man, aged 42, who died after a similar operation from meningitis, but the post-mortem revealed five other abscesses in the brain.

RADIUM LIGHT.

Holzknecht gave the Gesellschaft a history of his experiments conducted with Schwarz with radium light on patients suffering from nerve atrophy. In all their observations they cannot say that any good was obtained, although phosphorescent shadows were frequently observed. Practically speaking, they cannot support the notion that the rays of radium which are not refracted in any media will act beneficially on the diseased optic nerve, although Loudon affirms that he has obtained excellent results from its use by increasing the activity of an insensitive retina. Before further advance can be made it might be well to test the effects on animal tissue, as the light may possibly produce a nutritive action in the radioactive substance, thus producing phosphorescence in the media. From this it may be perceived that the action is not a direct stimulus of the retina but rather a radio-active condition of the surroundings that increases the nutritive action of the tissue.

Sachs was willing to accept the notion of a radioactive substance in the media of the eye, but doubted the beneficial effects that the light would produce upon the retina. Weiss said that he had seen equally good results by using the galvanic current for atrophy of the optic nerve, which he thought might account for many of Loudon's successes.

The Operating Theatres.

MIDDLESEX HOSPITAL.

APPENDICITIS.—Mr. A. CLARK operated on a man, aged 20, whose case presented some interest on account of the diagnosis. When first seen by Mr. Clark the patient had been under medical treatment some fifteen days: the history was that he had suffered abdominal pains with occasional diarrhoea and sickness. This condition continued for about a fortnight, nothing definite presenting itself. His temperature varied from just below 100° to 102°. On the fifteenth day the doctors in attendance discovered some induration in the right iliac region which seemed to point more definitely to appendix trouble, of which previously there had been suspicion. The patient was accordingly sent to the hospital and there the diagnosis of subacute appendicitis was confirmed. He was kept under observation a week, and there was no alteration in the symptoms from which he had previously been suffering, and there was a definite swelling in the right iliac region. Under these circumstances it was deemed wise to explore the appendix region. The usual incision was made and a number of adhesions having been broken down, the appendix curled up on itself with its tip adherent to
the cæcum was found. It was removed, and on opening it a nearly healed ulcer was found near the tip. There was a little trouble with bleeding from the adhesions, but pressure and patience completely controlled it. The wound was then sewn up layer by layer and the patient returned to bed. Mr. Clark remarked that until the induration in the iliac region pointed to the seat of the trouble there was no clue as to the cause of the symptoms, and the suggestion had been made of typhoid, more particularly as it was found that the drainage in the house in which the patient resided was not as it ought to be. As soon as the diagnosis was made it seemed desirable, he said, to wait for the attack to subside, but as this did not take place the operation above described was decided on. As regards the operation itself, the adhesions, he remarked, presented a little difficulty, more particularly as there was oozing from the bottom of the wound, which could not be controlled by ligature. This, however, as is usually the case, was stopped by pressure. The bleeding from the adhesions to the cæcum was easily controlled by ligature. It was quite clear, he thought, that operation was the right thing here. If the patient had been left it would either have gone on to suppuration and the patient’s chances of good recovery would have been less, or a very chronic convalescence with probable trouble from the adhesions would have resulted, whereas by the operation the patient was practically cured.

A week after the operation, he is satisfactorily convalescing.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

OPERATION FOR ECTOPIA VESICE.—Mr. Kellock operated on a boy, aged about 3½, the subject of complete ectopia vesice. The condition, which was, of course, a congenital one, showed little difference from other cases of this class. The posterior wall of the bladder was visible through an area as large as a five shilling piece, the mucous membrane covering it showed several pedunculated processes, but was otherwise in a healthy condition. The two pubic bones were separated by an interval of about two inches, each side carrying its own rectus abdominis muscle with it. There was a condition of complete epipadias, and by traction on the penis the openings of the lower ends of the ureters into the bladder could be distinctly seen. A finger passed into the lower part of the extroverted bladder was found to reach downwards and backwards, behind what should have been the symphysis pubis, so that the trigone and possibly the prostate gland were in their normal position. The scrotum was fairly developed and a testicle could be felt on either side just outside the external abdominal rings. The child’s general health was perfectly good, and he exhibited no other congenital malformation. Mr. Kellock said he proposed to divide the operation into two stages: First, to bring the penis and urethra into the perineum, and subsequently to attempt to remove the greater part of the mucous membrane of the bladder and close the opening in the abdominal wall. The child having been anaesthetised, incisions were made round the under surface of the penis and through the attachments of the bladder on either side as far back as the separated pubic bones. On deepening these incisions, the penis was thus more or less isolated from the surrounding tissues; an opening then having been made through the posterior part of the scrotum and anterior part of the perineum, the penis was drawn through this from below and fastened by horse-hair sutures in this position; the greater part of the median incision, which lay above the penis in its new position, was then closed. Three of the pedunculated processes of the mucous membrane of the bladder were then ligatured and removed by scissors. Mr. Kellock said that if the conditions remained satisfactory he proposed in about ten days or a fortnight to try and complete the operation of closure of the opening into the bladder.

[We hope to publish the second half of the operation in a future number.]

ERRATA.—June 24th. "Operating Theatres," p. 650, 2nd col.: Third line from bottom, for "ataxy" read "atony." Second line from bottom, for "detensor" read "detrusor."

HYGIENIC INSTRUCTION IN SCHOOLS.

One of the greatest hindrances to the diffusion of hygienic principles among the masses of to-day is their almost complete ignorance of elementary science as manifested by the tendency upon the part of some to regard all such endeavours towards the conservation of health merely as medical fads, while others of even a less enlightened degree treat them with absolute indifference or open contempt. It is, of course, a slow and difficult process to overcome the ingrained habits of a former generation, who argue that "what was good enough for them is good enough for their children." But it must be remembered that the conditions of life are not precisely the same as they were fifty years ago, and that the stress of toil is greater, and the competition far keener now than it was then. An altered set of circumstances demands a more careful and accurate adjustment of the human organism to its environment. Biological laws must be complied with unless the race is to suffer, and there can be no doubt but that the physical safety of the nation depends very closely upon the strict observance by its individuals of the laws of health. And how can these be kept unless they be known? Much has been and is being done by the lay Press to spread
and popularise the scientific principles of everyday life among the people, and the appointment of health visitors and lecturers in various districts is a most important step towards the systematic instruction in hygiene that is so urgently needed throughout the land. But it is to the rising generation that we must look in order to secure the greatest benefit for the country at large from the diffusion of knowledge of these matters. The systematic training of the young in understanding the more simple laws of health should not be regarded as superfluous, but as necessary for the school curriculum as the "three R's." The knowledge of the evils produced by dirt, of the rudiments of domestic economy, such as elementary facts with regards to infant feeding, clothing and ventilation, together with the principles of dietary and cooking, is quite capable of being presented in an attractive form to a child's mind. Many of these subjects are more suitable for study by girls just before leaving school, for it is in the home that their previous teaching can bear fruit, and the home-life is the touchstone of the nation's health. To supplement the class-instruction, practical experiments in the chemistry of respiration and of the common things of daily life would be of great value as serving to impress the drier facts upon the young mind. It is gratifying to note that the Board of Education includes in its syllabus for the higher grade schools a course of "Lessons on Common Things." Those medical officers of health who also happen to have seats on the local School Boards have used and are using their influence in endeavouring to procure a more systematic instruction in hygiene for the young. As an outcome of these efforts, the training of teachers in the necessary special subjects becomes a matter of importance. And here the various technical institutions have stepped to the front, so that there is now no difficulty whatever in the way of anyone desirous of taking up a course of theoretical and practical hygiene for the purpose of teaching its principles to others. The evening continuation schools also cater for the instruction of senior scholars and others who are engaged during the day, so that for a certain class there is ample provision for all who are willing to learn. The special need now is that children should receive lessons in the subject while they are yet at school, in order that their interests may be awakened and their intelligence quickened in these vital matters. Then when they leave school the science of hygiene will not be new to them and their minds will have been bent in the direction in which they will naturally incline, and habits will have been formed which cannot fail to exert a beneficial influence upon the lives and future offspring of the coming generation.

INFECTION ARTHRITIS.

The difficulties that surround the differential diagnosis of articular maladies are of a manifold nature. The secondary or symptomatic joint inflammation, for instance, may result from many causes, and the morbid process may involve structures not only within but also in the neighbourhood of the joint proper. Until comparatively recent years the wide and general term "rheumatism" has served the purpose of the practitioner called upon to deal with painful or tender articular troubles not obviously due to gout, rheumatic fever, tubercle, syphilis, injury, blood poisoning, or gonorrhoea. A rough classification of that kind clearly failed to include a large number of conditions that with greater care and increasing knowledge can nowadays be separated from the old-fashioned rubbish heap of "rheumatism." This important subject was dealt with in a valuable and suggestive manner by Mr. Howard Marsh before the Royal College of Surgeons towards the end of the year 1902. He pointed out that the modern views of infective arthritis in the first place started from the discovery by Weichelsbaum, in 1888, that the pneumococcus has the power of inducing an acute articular inflammation, which as a rule went on to suppuration, and in three-fourths of the cases ended in death. Other illustrations following specific fevers may be found in scarlatina, enteric fever, influenza, erysipelas, and glanders. Of the large number of unclassified septic arthritic diseases Mr. Marsh connected one case with toxins absorbed from a fritid bronchietasis. In another patient a diplococcus was isolated from the knee, and this organism injected into a rabbit produced a polyarticular affection. Other chronic articular inflammations, usually ending in fibrous or bony ankylosis, may be caused or complicated by one or more varieties of septic cocci. These observations are of the greatest importance to progressive medicine, and they will doubtless serve to stimulate other investigators, both medical and surgical, to further efforts in a similar direction. An interesting communication was published by Dr. William Murrell in the issue of the Medical Press and Circular for June 10th, 1903. The article was entitled "Diseases Commonly Mistaken for Rheumatism," and it would be hard to imagine a subject of more direct practical value to all practitioners of medicine. The author first passes in review the commoner morbid conditions, such as osteo-arthritis and influenzal articular inflammations, and the group of myalgias usually described under the name of "muscular rheumatism." He further reminds the reader that not infrequently pain in or about a joint may be the index in origin, as in the familiar example of pain in the knee due to tuberculous disease of the head of the femur, or perhaps symptomatic of renal or vesical calculus. The medical man who, in his everyday experience, bears in mind the existence of hysterical or mimetic joint affections will sooner or later find himself saved from a formidable pitfall of diagnosis. One point insisted upon by Dr. Murrell is worthy of especial attention, namely, the confusion of osteo-myelitis with rheumatism. As he rightly remarks, to make a mistake of that kind probably represents one of the greatest misfortunes that could happen to a man in practice,
but for all that the error, unfortunately, is not uncommon. It is important to remember, therefore, that acute suppurative osteo-myectesis occurs chiefly in young subjects, and is staphylococcic in origin. It attacks the bone in the immediate vicinity of the epiphysis, the common seats being the upper end of the tibia and the lower end of the femur. In addition to high fever and general constitutional disturbance there is pain on percussion over the affected parts. The treatment is to gouge out the diseased bone and administer antistaphylococcic serum internally. A typical case was published by Dr. Murrell in the issue of THE MEDICAL PRESS AND CIRCULAR for July 1st.

The two articles from his pen are worthy of being carefully read in conjunction with the Bradshaw lecture on infective arthritis.

THE COCAINE HABIT.

If we may judge from our exchanges, the abuse of cocaine in American cities has reached alarming proportions. Dr. Simonton, in a paper read before the Pittsburg Academy of Medicine, stated that three thousand ounces of cocaine is not an unusual amount to pass over one counter in the year. One druggist admitted that he sold from forty to fifty ounces a month. Large as is the direct sale of the alkaloid, as such it is small in comparison with the amount sold in proprietary preparations, which are vended as catarhhal snuff, consisting of tobacco, bismuth and cocaine, nerve tonics, stomach invigorators which are so freely advertised—the great American red blood corpuscle makers, that contain fully 50 per cent. of alcohol with cocaine, albuminoids, and so forth. In this way the habit is acquired, and in time the poor victim finds it is cheaper to buy the chemical separately. The habit has reached such proportions in many of the smaller towns that 50 per cent. of all the crime is credited to the use of the drug. Throughout many of the States the negroes are completely demoralised by its use. We refer to these things in order that some steps may be taken to ensure that in buying proprietary preparations the public may know what they are buying. Under a captivating title a purchaser may be buying a strong alcoholic preparation, with or without cocaine—a nerve invigorating wine, or mixture, a preparation that might under certain conditions be a very valuable medicine, but one which could not honestly be recommended for general use.

We think that it is necessary to take steps to prevent this demoralizing cocaine habit from spreading to this country, and we do not think that the public are sufficiently protected by the existing laws that regulate the sale of scheduled poisons. We should like to prohibit the sale of scheduled poisons in proprietary medicines, or their sale for internal use, except in a preparation prescribed by a registered medical practitioner, and that a prescription containing any such poison should not be repeated. As the law is, a prescription, no matter what poison it contains, may be repeated again and again, and is not infrequently lent from patient to patient. This calls for change, and the prescriber can do much to lessen this danger by stamping his prescription "not to be repeated." We would further desire that all proprietary preparations containing poisons have their exact formula written on the label, and that all those containing alcohol should have the quantity and strength of the spirit contained plainly marked both on the wrapper and label, so that a man may not unconsciously be bringing home to his sick child a cold punch and cocaine nerve restorer.

Notes on Current Topics.

The Requirements of the Science Schools in Trinity College, Dublin.

The appeal for funds issued on behalf of the scientific schools of the University, to which we have already referred, sets forth very clearly the amount of money required both for immediate capital outlay and for annual expenditure, and also shows the sums which ought to be placed at the disposal of the various schools. So far as medical science is concerned, seven schools are included in the list—viz., those of anatomy, chemistry, experimental physics, physiology, pathology and bacteriology, zoology, and botany. In the anatomical school an embryological laboratory is urgently required, and further teaching assistants. The estimated capital outlay amounts to £2,300, and the annual outlay to £150. The botany school requires a suitable building for teaching purposes and for the reception of the valuable herbarium and library, also additions to the teaching staff. The estimated capital outlay is £9,400 and the annual outlay £280. In the chemical school additional laboratory plant is required, and an additional assistant. The estimated capital outlay is £1,500 and the annual outlay £350. Experimental physics call for the greatest outlay, as the teaching accommodation is entirely insufficient, and there is also required almost new equipment. It is estimated that a capital outlay of £11,000 and an annual outlay of £350 are required. The pathological school does not call for such extensive outlay, in consequence of the sums which have been recently spent upon it. The estimated capital outlay is £1,000, and the annual outlay £150. The school of physiology does not require any capital outlay, as recent additions have been effected. The estimated additional annual outlay is estimated at £250. The school of zoology requires large additions both in respect of accommodation and of the teaching staff. It is estimated that capital outlay of £7,700 is required and an annual outlay of £546. The total capital outlay required amounts to £34,000, and the annual outlay to £2,730. If the latter sum is capitalised at 3½ per cent. we find that the total sum required is £112,000. This represents a large amount of money, and the graduates and supporters of Dublin University will have to respond to the appeal in a generous spirit. The munificent offer of Lord Iveagh has been already mentioned, and we sincerely trust that the University may be able
to collect the necessary amount to enable her to take advantage of it.

The Married Life of the Carlyles.

It is little less than sacrilege to draw aside the curtain which should ever veil the joys and sorrows of domestic life, and it is a relic of barbarism which allows the ruthless stripping of all-sacred draperies from the sanctity of marriage. But the sexual concerns of the Carlyles have become subject for common gossip, and the relations of Thomas Carlyle and Jane Welsh now afford matter for jest as well as for profound sorrow. We consider a very grave responsibility has been undertaken by those who, presumably in the interests of biographical truth, have dragged into the unprotected gaze of a selfish public physiological and psychological conditions which might well have been treated with such respect and reticence as has always characterised the procedure of the medical profession in regard to such matters. In a recent number we referred to Froude's contention that the only true explanation of the differences and misunderstandings which arose between these two exceptionally gifted souls was to be found in the impotence of the master man. Sir James Crichton Browne has now issued a peculiarly bitter and in many ways unfortunate and unsatisfactory reply to Froude's imputation, in which the charge is, as he calls it, "considered medically." He certainly succeeds in showing that there is strong circumstantial evidence that Carlyle was not the subject of any disability, as has been suggested. It is clear, however, that the childless state of the Carlyle home accounts for much in the wide separation of these two lives, wundered far though lived together. Sir James, in the introduction to the recent volume of letters of Mrs. Carlyle, and in his last effort to wipe all mud of slander and filth of false accusation from his much-beloved master, has hardly granted that charity which would protect Jane Welsh Carlyle from abuse. Indeed, much of his argument seems based upon a determined effort to glorify the man by despising and degrading the woman. The discussion is not creditable to the literary spirit of to-day. Such subjects must of necessity come within the scope of serious medical inquiry, and no physician desirous of serving his day and generation can afford to neglect a careful study of the psychological and physical states influencing or deranging sexual functions; but we think the reckless exposure of these matters in all their nudity to an ignorant and oftentimes lewd public opinion will be shown to be ill-advised and useless, and will bring shame and a measure of disgrace to all concerned in such exposure.

The Look Hospital and its Nursing Staff.

An awkward situation has, we learn, arisen at the Government Lock Hospital in Dublin in consequence of the resignation of three out of four staff nurses owing to the alleged impossibility of submitting any longer to the vexatious rule of the matron of the hospital. We are informed that the staff nurses in question have been in the hospital for many years, and have discharged their duties in every way to the satisfaction of the medical staff. The matron of the hospital is not a trained nurse, but a lady who has been advanced to that position from the post of housekeeper, and apparently the staff nurses consider she is unable to appreciate properly the relations which should exist between a lady superintendent of nurses and the nurses. Whatever may be the cause of the present state of affairs, it is a serious matter when in a hospital of the kind the staff nurses feel their position so keenly that three of their number resign and that the Board of Governors find it necessary to call upon the fourth to also resign, in consequence of a complaint brought forward by the matron. We regret to hear that the Board have refused by a majority vote to hold an inquiry into the causes which led to these resignations. Whatever they may be, the interests of the institution, and of all concerned, demand that such should be held, and the facts ascertained at first hand. We also learn that apart from the staff nurses other officials of the hospital find it difficult to discharge their duties without coming into conflict with the matron, and that in at least one instance a serious interference with the duties of the medical staff took place. This interference was at the time reported to the Board, and no effectual steps were taken to ascertain its cause. Should the facts of the case be as they are reported to us, it is incumbent on the Board to take steps to prevent the serious consequences which would arise from the sudden loss of all the staff nurses.

The Jenner Institute of Preventive Medicine.

The recently-organised antitoxin department of the Jenner Institute of Preventive Medicine, at Elstree, was visited on Friday last by a large number of distinguished scientific and other selected guests, who attended in response to an invitation issued by Lord Lister and the governing body. The resident staff, consisting of Dr. George Dean, Dr. Todd, and Dr. Petrie, received the party and conducted them over the laboratories, which are devoted to the preparation of antitoxins on a commercial scale as well as to investigations bearing on immunity. The place was formerly a breeding establishment for horses, and is admirably adapted for its present purpose, containing as it does accommodation for thirty-six horses. The horses, peering curiously from their boxes at the unusual influx of visitors, looked perfectly comfortable, although they bore sundry sinister labels—diphtheria, tetanus, streptococcus, and the like. Even the much-experienced guinea-pig looked the picture of happiness though inoculated with this or that toxin or virus. The arrangement of the laboratories, it is hardly necessary to add, leaves nothing to be desired in the actual state of our knowledge, with their papyrus floors, glazed adamant walls, white tiles and large windows. In the garden are small houses for the isolation of the smaller animals. Inter alia, some highly interesting preparations were shown of the results of the inoculation of animals with human tubercle, proving
clearly enough that the virus is capable of giving rise to disseminated tuberculosis. Along with Lord Lister were present Lord Ieavegh, Sir Michael Foster, Sir Henry Roscoe, and Dr. Macfadyen (the chief bacteriologist), Sir William Church, Surgeon-General Sir W. Wilson, Dr. Castellani, Sir Felix Semon, Dr. Collingridge, and Dr. Seaton. It was generally felt that this country is now in possession of an institution worthy of it, and of the important functions which it is intended to fulfil. Thanks to the munificence of Lord Ieavegh it has been possible to render available the most perfected apparatus and appliances, both for the preparation of sera and for further research.

A Judge’s Comments on Medical Charges.

The question of what constitutes a suitable charge for medical attendance is obviously one which can only be answered in view of the conditions under which the attendance was obtained. But some remarks which fell from the judge at the Winchester Assizes last week may be taken to formulate a principle likely to command general assent, quite apart from the merits of the particular case. A man, who thought he had been poisoned, consulted a local practitioner, complaining of collapse, nausea, &c., and was given a bismuth draught. He was visited at his house twice on the following day, but it was not thought necessary to give him any medicine. For these three attendances a bill of three guineas was presented, and formed part of a claim for heavy damages against the manufacturers of the incriminated drink. The judge elicited from the practitioner that he was not in the habit of charging a guinea a visit under ordinary circumstances, but did so on this occasion because it was an "emergency" case, whereupon the judge animadverted strongly on the impropriety of a professional man sending in an exaggerated bill on the chance, apparently, of its being recovered from the defendants. It was, of course, open to the practitioner to say that his charges were regulated by the social position of his patient, and it is difficult to see what objection the judge could have taken to the practice—which is universal. We do not, however, desire to discuss the merits of this particular case, but rather to point out that it is unquestionably undesirable and improper to charge in such cases on a special scale on the assumption that the defendants will have to pay.

The Surgery of Chronic Bright’s Disease.

Many morbid conditions which were at one time considered incurable, and therefore only to be mitigated by drugs, have yielded successfully to the rapid advances of modern operative surgery. Such regions as the interior of the cranium and certain of the internal viscera, hitherto deemed inaccessible to the knife, are now daily explored in every operating theatre in the land. The principles of asepsis have rendered this possible. Other diseased states there are which do not seem amenable by their very nature to surgical treatment. Chronic interstitial nephritis is one of these, and has been variously regarded as a slow degenerative process in which toxins play an important part. Since the discovery by Edelbohs, of New York, of the fact that persons affected with granular kidneys in whom nephropexy had been performed for mobility of one renal organ were improved with regard to their chronic nephritic symptoms, it occurred to that observer to perform nephropexy in granular kidney alone, with the result that many patients were benefited and some appeared to be even cured of their complaint. Thus it has come to pass that "renal decapsulation" or "decoration," as the new operation is termed, is likely to find a permanent place in the therapeutics of chronic Bright’s disease. The beneficial results in many cases of the operation, which was almost simultaneously performed by Ferguson, and has since been practised by surgeons in this country, are attributed to the increased circulation through the kidneys owing to the development in the peri-renal adhesions of new collateral channels. It is stated that these vessels have been observed in the lower animals, but it is very difficult to produce in them anything exactly corresponding to the true granular kidney found in the human subject.

Fireguards in Workmen’s Dwellings.

The number of children sacrificed yearly owing to the want or neglect of proper precautions is simply appalling. Thus, in England last year there were 1,684 inquests held upon children burnt to death, and in 1,425 of these the fact was elicited that there were no fireguards in the rooms where the accidents occurred. These articles are not expensive, and their absence in the living-rooms of the poor is negligible on the part of the parents, and is evidence of deplorable shortsightedness on the part of the authorities who have built or who own the tenements in question. It should be made compulsory that all the new workmen’s dwellings which are rapidly being run up in different parts of suburban London and other great cities should be supplied with properly constructed fireguards in all living-rooms. Cupboard room may be a most excellent thing, but the furnishing of these habitations with simple structures which are the means of preventing much loss of life is, surely, more to be desired.

The Anti-Tuberculous Properties of Muscle-Juice.

The mortality from the various forms of tuberculosis, general, pulmonary and meningeal, affecting young children is very considerable, particularly in the crowded areas of our great cities. The virulence of the infection is largely increased by unhealthy surroundings, bad air and insufficient or improper food. There are few remedies which seem to possess any influence at all upon the progress of the disease in its acuter forms, but much can be done in the early stages to check its hold upon the system, while still more, of course, can be achieved by preventive measures. MM. Alberti, Josias and Jean-Ch. Roux, in a communication read at the recent International Congress of Medicine at Madrid, have had some rather more hopeful results from the administration of muscle-juice
and raw meat in infantile tuberculosis. As was to be expected, the more acute forms were apparently uninfluenced, but in a series of sixteen cases of early meningeal and pulmonary tuberculosis six were cured, four were greatly relieved, four slightly improved, and two died. An increase in weight was one noticeable result of the treatment. It is often remarked how readily young infants will take meat-juice and what changes it is capable of producing in the character of the stools when these have been offensive owing to intestinal fermentation. In marasmic states the same substance may prove the one thing needful to cause a turning-point in an otherwise fatal illness. The abundance of nucleo-proteids and albumins in muscle-juice probably fortify the tissues so that they are more able to resist the invasion of the bacilli to a greater extent than milk is capable of doing. It is an easily obtained remedy, it can be home-made if necessary, while it should afford a good substitute for cod-liver oil, now that that drug is becoming scarce.

Mr. Allinson and the Coroner.

Mr. Allinson, ex-L.R.C.P., was severely criticised by the Kingston coroner on the occasion of an inquest on the body of a lady who had been attended by him and died of cancer. It transpired that no treatment had been adopted and no operation advised, and the coroner contrasted the curious latitude allowed by the law in respect of human beings with the strict way in which it controlled diseases in animals. Mr. Allinson, who boldly asserted that he was "an authority in himself," claimed to have a practice "second to none in the Kingdom," adding that registrars never made any difficulty in respect of his certificates of death, either in town or country. If this be the case it only emphasises the urgent necessity for reform in the registration of the cause of death. If the certificates of Mr. Allinson, a man whose name was removed from the Medical Register for infamous conduct in a professional respect, are really received with this unanimity, what guarantee have the public, and what measure of credence can be accorded to such documents?

Cryoscopy as a Clinical Test.

The knowledge of the exact manner in which the renal organs perform their duty is often the key to the diagnosis of certain systemic disorders. It not infrequently happens that the finding of a single granular cast in the urine is sufficient to alter completely the opinion of the physician or to confirm his suspicions, while on this sole microscopic evidence has rested the non-performance of many surgical operations. In order to estimate renal efficiency recourse must be had to certain clinical tests, in the application of which the sister sciences have come to the assistance of medicine in providing the various instruments of quantitative analysis with which every student of medicine is familiar. Dr. Tinker, of the Johns Hopkins Hospital, considers that cryoscopy is of great value as an index of renal insufficiency, especially in surgical affections of the organs. As applied to medicine, cryoscopy has been employed by Koranyi, Moritz, Senator, Kümmer, and others, who believe that the freezing-points of the urine and of the blood afford the most trustworthy indication of the condition of the kidneys. That of the blood is the more accurate, as being less influenced by physiological variations than urine. In the case of the latter, a freezing-point above 0° C., and for the blood, over 1°58° C., shows that renal insufficiency is present. In determining the relative working capacity of the two kidneys, as, for instance, previous to a nephrectomy, catheterisation of the ureters should be practised, and a separate cryoscopic examination made for each sample of urine. It is claimed that the method is not more time-consuming than many other clinical tests in everyday use, while it is more trustworthy and accurate than most of them.

The Ferments of the Amniotic Fluid.

Apart from the mere mechanical action of the liquor amnii in preventing shocks and jars to the fetus during its growth and its valuable function in acting as a fluid wedge in the first stage of labour, it has not been supposed to minister nourishment to the embryo or to exert any definite influence upon its metabolism. It is known to contain albumin, the proportion of which is larger in the earlier months of pregnancy, and also urea, which is generally found towards the later months: M. Biondi, of Vienna, in the course of some researches upon the composition of the amniotic fluid, claims to have discovered no less than five different ferment therein. One of these is allied to fibrin ferment, while the others are proteolytic, amylo-lytic, and lipolytic. These bodies are considered to be derived from the maternal blood and to be absorbed in the intestinal canal of the fetus, where they dissolve albuminous substances found therein. Though it would be of greater value if the relationship between the presence of the ferments and the age and general condition of the fetus was more fully investigated, yet this discovery in the chemical physiology of the liquor amnii is one of importance as tending to illustrate the predominance of the chemical and vital action of the fluids of the body over the purely physical.

Excision of the Urethra.

At the May meeting of the Société des Sciences Médicales, M. Cavillon exhibited for Professor Jaboulay a portion of a urethra, about five centimètres long, which he had excised from a man who was suffering from tuberculous disease of the kidney. The patient had for the past four years complained of urinary troubles, and some four months prior to his coming under the care of Professor Jaboulay a renal or peri-renal abscess was incised. On admission to hospital there were evidences of a collection of matter in the neighbourhood of the kidney; his urine was purulent, the bladder was suffering from cystitis, and his condition was such that he desired to have his kidney incised. This gave him considerable relief, but after a few days his temperature rose, his state indicated a fresh
collection of pus, and he became anxious that a radical operation be performed. After assuring himself by catheterisation of the ureters and use of the methyl blue test that the left kidney was normal, M. Jaboulay decided to operate. He, on exposing the gland, opened all the pockets of pus, both intra-renal and peri-renal; the ureter was next examined, and was found to be tuberculous; it was therefore ligatured above and below, and the portion between the ligatures was excised. This operation has been performed twice before by M. Jaboulay, the first time for a sarcoma of the kidney in a very cachetic patient, who did not long survive the operation; the second case was that of a woman who was suffering from pyonephrosis; in this case the operation was supplemented by a nephrotomy. This patient made a very good recovery, and there is evidence that the diseased kidney has undergone atrophy. The operation presents many advantages; it is a more simple operation and more quickly performed and less dangerous than nephrectomy. It isolates the urinary bladder from the diseased products of the infected kidney, and excludes infection from the healthy gland, hence M. Jaboulay designates the operation "isolation of the kidney." Ligature of the canal produces atrophy of the gland. This atrophy is gradual, and during its occurrence the healthy kidney is becoming hypertrophied and more capable of carrying out the increased work thrown on it. Exclusion of the kidney may be performed with or without nephrotomy. The operation stops the functional activity of the gland, it excludes it completely, and atrophy results as a consequence, just as it is found to occur in hydronephrosis. It is a physiological fact that glands atrophy when the excretory duct is completely closed. With Dr. Gauthier we conducted a series of experiments to learn the influence of occlusion of the ureters on the kidney affected and on the kidney whose ureter was not interfered with. We may, for the present, content ourselves with saying that in the case of rabbits and dogs in whom we ligatured and excised the ureters we have not found that reflex inhibition of the opposite side which some writers refer to; neither did any one of those animals suffer from urinary phenomena.

An Aseptic Operation Theatre.
The ideal operation theatre is an aseptic one; to obtain this many ingenious and useful mechanical devices have been adopted. The walls, ceiling and floors have been covered by impermeable material that admits of the room being flushed out regularly, and the replacing of the corners by curves has left no pockets for matter to collect. The use of furniture that can be made aseptic, and the separation of the spectators from the operator and the patient by a wall of glass, have all tended to approximate the condition of the theatre to the ideal. But M. Tuffier has, by some ingenious experiments demonstrated to the Société de Chirurgie, of Paris, that when all these precautions are taken the atmosphere is still rich in germs. He proposes that a vapour cloud of oxygenated water, generated at a high pressure, be passed into the room until the whole space is filled. After such a saturation of the air he finds the volatile germs have become too heavy to float, and that they have to a certain extent become less separate entities and more conglomerate masses. The whole air becomes washed, purified and practically aseptic. The scheme much resembles the antisepctic purification method by steam vapourisers that were used in the early days of Listerism, and were found so disagreeable by the operator and his assistants. At that time, however, the vapour was directed on the field of operation, with the object of keeping the atmosphere in the vicinity of the surgical wound sweet. By the method of M. Tuffier the vapour cloud is much finer than the Lister spray was, and the whole space of the room is purified without in any way interfering with the surgeon's comfort, for the process is completed before the patient is brought into the theatre. As an addendum to other methods of purification, especially in private houses, we think it worthy of a trial.

The Erythema as Disease Indicators.
The very intimate relationship in which dermatology stands to general medicine is one which is gradually becoming more recognised both by specialists and physicians. The cutaneous surface, like that of the tongue, affords a valuable index of the state of the blood and the internal organs. This connection was strongly insisted upon by Dr. James Galloway in the Annual Oration before the Dermatological Society of Great Britain and Ireland on June 24th. One of the commonest signs upon the skin of disease is, perhaps, an erythema, and erythematous eruptions form a group of great complexity and of no small insignificance. In vaso-motor disorders, a persistent erythema of the extremities is not infrequently seen, quite apart from the more familiar chilblains. Sometimes the rash is almost universal, in which case the prognosis is apt to be unfavourable. Considering the close relation between the renal and cutaneous excretions, it is not surprising to find that severe erythema, of an exudative type, is often present in the later stages of Bright's disease, and here again the outlook is very grave. Absorption of toxins from the alimentary tract is capable of giving rise to various eruptions of this nature. Regarded from this point of view, it does not seem improbable that erythematous lupus may be related to the erythema group by closer ties than would appear at first sight.

The Purity of Aerated Waters.
From time to time our attention has been called by correspondents to the apparent absence of sanitary control over the various brands of aerated waters on the market, and samples have been submitted to us which really seem to point to the lack of an efficient system of control. Several samples were decidedly turbid, and in some instances the appearance of the bottles or syphons suggested defective cleansing. In view of the confidence which the public place in such waters their manu-
facture ought to be closely investigated, more particularly in respect of the source of the water employed and the precautions taken to ensure its original purity and protection against subsequent contamination. The use of second-hand bottles is another point worthy of attention. A large proportion of the bottles pass through a chequered career before they find their way back to the manufactory, and they not infrequently serve as receptacles for paraffin, carbochloric acid and other poisonous or objectionable substances. Then, too, the popularity of the rubberised screw stopper for bottles is a possible source of contamination, since impurities may lurk behind the rubber band and so jeopardise the purity of the prepared water. There is no reason to suppose that carbonic acid gas possesses the property of sterilising impure water, and even were this the case it would afford no justification for the absence of the usual precautions. It is especially in regard to small manufacturers that suspicion arises, and there is no obvious reason why waters offered for sale should not be subjected to as stringent surveillance as milk, for instance. An official report on the results of a systematic inquiry into the quality of artificial drinking waters would assist the public in their choice, and we note en passant that Dr. Hamer has drawn up a report which to some extent covers the ground.

The Society for the Study of Inebriety.
At no previous time has the study of inebriety been approached in a more scientific spirit. The impulse of the age is being clearly revealed in the thoroughness with which moral and social problems are being attacked from their physical and psychological aspects. Alcoholism in its many forms is a danger which threatens much disorganisation to the State. Ignorance, apathy, prejudice have for long hindered the spread of sound scientific principles regarding the nature and management of inebriety. In 1884 a society was formed, mainly through the far-seeing enthusiasm of the late Dr. Norman Kerr, “to investigate the various causes of inebriety, and to educate the professional and public mind to a recognition of the physical aspect of habitual intemperance.” The publication of the “Proceedings of the Society for the Study and Cure of Inebriety,” has done much to develop the true spirit of investigation. The Council of the Society have now extended the range of their influence and are issuing under their direction “The British Journal of Inebriety.” The Society is fortunate in having the support and sympathy of many of the most distinguished members of the medical profession, and a large number of influential laymen co-operate as associates. The recently issued Journal contains a valuable Presidential Address by Dr. Harry Campbell, an important study on “Inebriety in Scotland,” by Mr. Arthur Sherwell; an essay on “Inebriety and Suicide” by Dr. W. C. Sullivan, “Notes on the Bremen Congress on Alcoholism” and much other material which should prove invaluable to all connected either directly or indirectly with work concerned in the restoration or alleviation of the unhappy victim of alcoholic excess.

The History of Medicine.
For the due appreciation of the present position of any science it is not enough merely to be acquainted with the discovery of the fundamental truths or even of more recent developments. It is of equal importance that the mind should travel back over the past centuries to the first glimmerings of knowledge in order to comprehend in the fullest degree the vastness of the subject and its gradual evolution from chaos. For graduation in theology, law, arts, science, and music, in most Universities, a knowledge of the history of the subject is considered essential, and questions thereon are included in the pass-papers. It is, therefore, somewhat strange that no such demands are made upon the student of medicine, for although this deficiency in the curriculum does not make him any the worse physician or surgeon, yet it must be acknowledged that it has a tendency to narrow his whole conception of medical science. The institution of the Hittor Lectureship by the Royal College of Physicians on “The History of Medicine” is a noble attempt to arouse interest among the profession in this little studied branch of the healing art. It would be a distinct gain if the Universities and their attached medical schools could see their way to establish a Chair of Historical Medicine in their midst, while the inclusion of the subject in the curriculum would then be only a matter of time.

The Prevalence of Actinomycosis.
The etiology of actinomycosis is still enveloped in some mystery, and although the disease is unquestionably transmissible from animals to man it appears highly probable that the principal source of infection derives from the vegetable kingdom. During the last five years no less than 86 cases of the kind have been reported in France, in 67 of which the disease affected the cervico-facial region. During the same period 189 cases were observed in Russia, 102 in the United States, 101 in Germany, 35 in England and 22 in Italy. Of 306 cases of cervico-facial distribution 10 died, 3 were reported to have improved, and 168 recovered, so that this distribution justifies a favourable prognosis. As might be expected, infection of the thoracic or abdominal walls is a graver form of the disease, only 16 having recovered out of 25. When one or other of the viscera is infected the prognosis is decidedly grave, death being the rule. The most remarkable point in respect of the treatment is the remarkable effects of iodide of potassium in some cases and its comparative uselessness in others, and this difference of results suggests the possibility of there being more than one variety of the disease. It has, in fact, been shown that a very similar affection in Brazil is due to a special bacillus, the actino bacillus, which is peculiarly amenable to the action of the iodide. It is therefore possible that, in some cases at any rate, other agents than the actinomycetes
may be concerned in its production, and the point is one which urgently calls for careful investigation.

Health and House-Boats.

With the coming of summer's heat the dusty and weary Londoner longs for the cooling shade and refreshing breeze of his much-loved river, and the rush of the lazy and leisured to the Thames has already begun in good earnest. It is not our purpose to dwell on the athletic and fashionable aspect of aquatic delights, but to focus attention on the peculiar benefits which life on a well-designed and suitably-conducted house-boat may afford to the innately delicate or constitutionally feeble individual. Such an outdoor existence is compatible with river residence for many susceptible to the various morbid influences peculiarly associated with town life—on the hot days of summer a means of avoiding derangement and securing prophylactic powers of the highest utility. Many asthmatics, consumptives and subjects of nervous instability now avail themselves of the restful and invigorating influences of river life. We venture to think medical men might well bear in mind the advantages of the house-boat as a therapeutic agent of the greatest utility when selected with judgment and residence is conducted with reason.

Sir Patrick Manson.

Among the recent Birthday honours, briefly recorded in our last issue, none were more deservedly awarded than the distinction granted to the medical adviser to the Colonial Office. The new Knight Commander of the Order of St. Michael and St. George occupies a high place among English pioneers in medical science. His researches into the pathology of tropical diseases have done much for the betterment of mankind, and his enthusiastic efforts to further the proper study of malaria and other tropical diseases are justly described as Empire-making. We offer Sir Patrick Manson our hearty congratulations.

The death is announced of Dr. William Morrison, medical officer in charge of plague patients at Kalyan, Bombay, as the result of a fall. It is surmised that he must have slipped in the dark and fallen over the banister. Dr. Morrison was a graduate of the University of Edinburgh and was sixty years of age.

PERSONAL.

Dr. H. A. ALFORD NICOLLS, C.M.G., Medical Officer of Dominica, has left that Colony for Canada on leave of absence.

SIR EDWARD CARSON will preside at the Distribution of Prizes to the students of the Dental Hospital of London on the 17th inst.

Dr. SEYMOUR TAYLOR, physician to the West London Hospital, has been elected President of the West London Medico-Chirurgical Society for the ensuing year.

The Hon. Dr. C. DENNEY, who has been connected with the Medical Staff of St. Lucia for thirty-two years, has been retired from the public service of the Colony under the age limit rule.

The governing body of the Jenner Institute of Preventive Medicine have appointed Professor C. J. Martin, F.R.S., of the University of Melbourne, to the post of Director of this Institute.

DR. A. R. URQUHART, Medical Superintendent of the James Murray's Royal Asylum, Perth, has been elected Chairman of the Parish Council of Kinnoull and appointed Justice of the Peace for the County of Perth.

Dr. G. V. POORE has been presented by his colleagues with a piece of plate and a testimonial, in recognition of his valuable services as Professor of Medicine at University College and as physician to University College Hospital.

LORD LISTER, in recognition of his "long and valuable services to the country, and particularly to surgery by the discovery and application of the antiseptic treatment," was admitted to the honorary freedom of the Merchant Taylors Company on Wednesday.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

[FROM OUR OWN CORRESPONDENTS.]

SCOTLAND.

INDIAN STUDENTS IN EDINBURGH.—An appeal for funds to provide permanent quarters for the Edinburgh Indian Association has recently been circulated both in this country and in India. Starting with a mere handful of members twenty years ago, with the object of assisting natives in India coming to Scotland for study or business purposes, promoting social intercourse among them, and holding debates on topics of interest, the Association has now on its roll about fifty members, and cannot, therefore, as was originally designed, meet in the private lodgings of its members. It is estimated that a sum of about £5,000 would meet the needs of the case, and donations should be sent to Professor Kirkpatrick, University of Edinburgh, the honorary treasurer, D. S. Rama Chandra Rao, M.A., President of the Association, or A. N. T. Vizarat, honorary secretary, the University House, Edinburgh. With the prosperity of the Australian and South Africa clubs before us, there can be little doubt that a similar institution for natives of India would prove a great boon to those coming from that part of our Empire, and would enhance the educational advantages which Edinburgh already affords them. It is to be hoped, therefore, that the appeal, which has the support of Sir William Muir, the Principal of the University, Sir Thomas H. Fraser, and the Dean of the Faculty of Medicine, will meet with all needed support, not only among wealthy natives of India, but among those interested in this country.

MILK PROSECUTIONS IN SCOTLAND.—The authorities have recently been unusually active in prosecuting sellers of milk which is not up to the average standard, and, considering the paramount importance to the health of the community of a plentiful supply of genuine milk, it is simply lamentable that it is so often impossible to secure convictions. Sheriff Gillespie gave judgment in three cases in Dunfermline last week, and in one a fine of £12 was inflicted on a dairymen for selling milk which was deficient in cream to an extent of no less than 44 per cent. In the other cases the defence was that the milk was sold as it came from the cow, and in one case the dairymen pleaded in addition that the milk-can bore a label with the words,
not guaranteed three per cent." In the first of these the milk contained only 2.72% of fat, and the Sheriff allowed this to pass, remarking that it must not be thought that milk of similar strength would be passed again. The case was removed from the court on the ground that the milk was not taken under the Act, and it was not to be proved to be adulterated. If the proposition of the magistrate in this case—namely, that until the Government issue a new circular that no milk should be sold if under 3% per cent. he cannot convict—is generally acted upon, it is to be feared that a legal standard of milk be set up. In fact, if the law cannot prevent the sale of adulterated milk, then, emphatically, it is a law is a bane.

Dundee Sanatorium for Consumption.—The annual meeting of the subscribers to this sanatorium, opened only a few months ago, was held on June 30th. A very large part of the cost of construction, which will ultimately amount to £35,000, has been met by the generosity of ex-Provost Moncur. About thirty patients are now under treatment, and the institution will in future accommodate forty, some of whom will be paying, and others non-paying cases. The cost of carrying on the work is expected to be about £4,000 per annum, of which about £2,000 will be derived from paying patients, about £1,000 from donations and gifts, and about £1,000 from annual subscriptions. Dr. Stalker, of Dundee, and Dr. Mitchell, of Edinburgh, were appointed as Sanitarists. The system so long in use in the sanatorium had not had a fair chance, since a number of patients had been waiting for admission, and it was therefore inestimable that many who had been ill for a long time were admitted. In future, however, only cases which offered fair prospect of cure would be treated. The sanatorium is situated on the Sledaw Hills, near Dundee.

BELFAST.
The Corporation and Consumption.—At the special meeting of the Cemetery and Parks Committee of the Corporation, held on the 30th ult., a deputation attended from the Public Health Committee to ask that the committee should be allowed to erect shelters in the walled-in enclosure of the Ormeau Park for the benefit of persons suffering from pulmonary tuberculosis. They referred to the recommendations made by Dr. Moritz, Medical Officer of Health, Manchester, in the memorandum submitted to the Institute of Public Health in Manchester last September. The author of the paper dwelt on the large number of phthisical patients who were either waiting to be admitted to sanatoriums treated but not quite cured, or were too ill for admission under the present circumstances, where such institutions only admit early cases. For all such cases he advocated the adoption of the plan now carried out in Berlin and various other Continental towns—a tract of ground being provided and fenced in, shelters built and furnished with cane couches, and offices and kitchens built where patients could be provided with milk, dinner and other food. For this purpose the city either pay cost price, or receive free tickets to obtain it. A medical man superintends the institution, but every patient remains under the care of his own medical man. The object is to have the whole institution in Berlin was about £350, and it shelters 150 patients daily, all returning to their own homes at night. The cost of milk, dinner and tea for these patients averages 9d. per day each. The members of the Cemetery and Parks Committee was opposed to this, but they would be prepared to consider the application. At a general meeting of the Corporation next day the whole matter came under discussion. Mr. Williamson, the chairman, referred to the scheme and said that the Corporation had no intention of adopting it. He reminded the members that when the Forster Green Hospital purchased land opposite to the park and proposed to build a new sanatorium there, there was a great outcry about the dangers it would involve, and they were compelled to move further out of the city. Certainly the general idea of such a shelter seems good, but it would be easy to find a better site than in the Ormeau Park, one further removed from the crowded streets surrounding that park, whose whole area is just one hundred acres.

Portrait of the late Professor Cuming.—An excellent portrait of the late Dr. Cuming, painted by Mr. Henry R. Douglas, has been presented to the new Royal Victoria Hospital, to be hung in the Cuming Ward. It bears the inscription: "James Cuming, M.A., M.D., Professor of Medicine, Queen's College, 1852-1889. Presented by F. R. and E. R. F. Cuming, in memory of a loving and deeply-valued friendship, June, 1903."

Correspondence.

PUBLIC SENTIMENT AND VENEREAL DISEASES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sir,—As one who was present at the International Prophylactic Conferences at Brussels in 1890 and 1902, may I append to your article of the 17th inst. on this subject a word of much-needed warning ?

The year 1868, the date of the Conferences, and the year in which the first Brussels Conference heard with amazement the passionate and despairing tones in which its most brilliant spokesman, Professor Fournier, of Paris, spoke of the prevalence of syphilis in that capital. All the means used had, he said, been unavailing to check the spread of the disease, nor did he anticipate that they would be any more useful in the future than in the past. Without going so far as some of his younger colleagues and proposing to do away with the system entirely, he considered that success must rather be looked for from other measures, i.e., the opening of State dispensaries on a large scale, free to all comers, the rigid exclusion of girl minors (who are the most dangerous) from the ranks of prostitution, and the enlightenment of the public as to the dangers of a false security. He stated at great length on the responsibility of the press, which, he observed, is the great instrument of public opinion. It was but the other day that he was present at a meeting of the medical profession at Brussels, at which the question of the prevalence of syphilis in that capital was discussed. It is certain that the greater part of the audience was composed of medical students, and the recent figures as to the prevalence of venereal disease in Belgium are published with the utmost frankness by the popular newspapers of the country. It is not to be wondered at that this does not prove an actual increase of disease, but only its being more commonly recognised.

I should like to draw your readers' attention to the report (Complete Record) of that Conference, which is full of the most instructive points. I learned to my surprise some time ago from Messrs. Williams and Norgate, the English agents, that they had not sold a single copy. Unfortunately, it is in French, and, so far as I know, the only English résumé of the debates is that given in a threepenny pamphlet published by Burfoot, Lewisham, entitled "Preventive Hygiene." With regard to notification, again, the difficulty is a practical one. There would probably be a wider difference between the actual and theoretical results of such a measure. Its first and most obvious consequence would be that no venereal patient would dare to go near a doctor. An experiment in the way of compulsory detention of patients was tried some years ago in Glasgow, but was discontinued, "as it only led to concealment of disease. The recommendation you quote from the American Medical Committee, namely, that the difficulty should be dealt with by "means not regulamentative, but social, economic, educative and sanitary," seems broad and sensible, and individual medical men can lend valuable aid, by popularising the knowledge of the various ways in which infection is incurred, and by urging immediate and prolonged treatment where such infection has actually taken place.

I am, Sir, yours truly,

R. LEPPINGTON.

(Member of the International Prophylactic Society, Brussels.)
THE LEGAL INTERPRETATION OF THE DENTISTS ACT.

To the Editor of The Medical Press and Circular.

SIR,—If the magisterial decision in the case reported under the above heading in your issue of June 17th is upheld by the High Court, it will be bad for the dental profession and worse for the public. Through the operation of the Dentists Act there has virtually been created a body of professional men highly qualified for the practice of their branch of surgery, and in numbers steadily increasing up to the requirements of the public. If the slight protection supposed to be afforded by the penal clauses of the Act can no longer be relied upon, and if the public will in future have little or no means of distinguishing between qualified and unqualified practitioners, the number of candidates for the profession will surely diminish, and the public will be left more and more in the hands of uneducated mechanics, whilst the fraudulent quack who finds so profitable a field for enterprise in dentistry will be enabled to carry on his trade with complete impunity. It is customary to make light of dental diseases because they do not commonly involve questions of life and death; but, as recently illustrated in your columns, these diseases do inflict a vast amount of suffering and give rise to many disorders of the general health. It is impossible to reduce the treatment of any case in dentistry to a merely mechanical process. Questions of surgery which must be dealt with are nearly always present, and, except in rare instances, even in the fitting in of a set of artificial teeth; and as ignorance is closely allied to cruelty it is impossible for an operator who ignores surgical considerations to avoid constantly inflicting unnecessary suffering or injury upon his patients. The mere mechanic ought not to be allowed to practise dentistry, or, at least, should not be allowed to assume any title implying that he is a qualified dental surgeon; and, there should be provided some means in dentistry, as in other branches of the medical profession, of enabling the public to perceive, at least, that the blatant advertising quack is not a legally qualified practitioner. The quack dentist is only less harmful than the quack doctor because his power is less extensive; and it is a painful, if not demoralising, spectacle to see many of these rascals amassing wealth mainly by the plunder of simple or foolish women, whilst the educated professional man struggles along in comparative poverty. It is open to complete proof that amendment of the Medical and Dentists Acts to prevent such abuses would prove far more beneficial to the public than to the vested interests of the profession, and it also seems to me that if the voice of the united professions could be made audible, loudly and persistently, the reforms so urgently called for must before long be conceded by the Legislature.

I am, Sir, yours truly,

June 23rd, 1903.

M.R.C.S., L.D.S.

THE FINANCES OF THE ROYAL COLLEGE OF SURGEONS, IRELAND.

To the Editor of The Medical Press and Circular.

SIR.—It is commonly reported that the Council of the Royal College of Surgeons, Ireland, are about to expend a large sum of money in the erection of a banqueting Hall, when funds are urgently required for more important purposes. Surely the Council could not think of thus allocating the college funds without consulting the general body of Fellows, many of whom certainly object to any such expenditure.

I am, Sir, yours truly,

An Old Fellow.

An inmate of the St. Andrew's Private Asylum, at Northampton, died a few days since as the result of the ingestion of a quantity of yew leaves. He fell suddenly ill, became unconscious, and died within an hour. An exonerating verdict was returned at the inquest.

THE ILLNESS OF THE POPE.

The news that His Holiness has developed what is described as senile pulmonary consolidation, news which is confirmed by our own correspondent, may excite regret without surprise. For some months past signs of reduced vitality have from time to time found an echo in the press, and we are now face to face with the usual consequence of cardiac inadequacy, viz., pulmonary stasis, a variety of pneumonia akin to the hypostatic pneumonia met with in the course of many debilitating affections of which old age may be classed as one. Dyspnoea, without marked febrile reaction, appears to have been the initial symptom; but, in spite of the guarded prognosis formulated by Dr. Lapponi, the affection is one which may be expected to run the usual downward course. Recent visitors to the Vatican were struck with the almost diaphanous emaciation of the illustrious occupant of the Chair of St. Peter. The intellect, it is true, resisted the process of physical decadence, and even now, with the calm and resignation begotten of a long and arduous life, His Holiness has been enabled to make the necessary arrangements with perfect lucidity of mind. The spectacle of this august ecclesiastic sinking painlessly and with dignity into the tomb recalls Goldsmith's lines:

"As some tall cliff that lifts its awful form
Swells from the vale and midway leaves the storm.
Though round its breast the rolling clouds are spread,
Eternal sunshine settles on its head."

SPECIAL ORIGINS. (a)

These two essays, in spite of a somewhat lengthy tediousness, afford evidences of much painstaking research and careful thought, and will be welcome to all human biologists as throwing light, although by no means clear and guiding, on a peculiarly difficult and perplexing problem.

The second essay, "Primal Law," the work of the late Mr. James Jasper Atkinson, should on all counts have been allowed first place in the order of this volume. Mr. Atkinson devoted the greater part of his life to a study of the principal doctrines of the divines of the New Caledonian Archipelago, from which he discovered what he conceived to be the "Primal Law" and origin of morality as regards the family. His monograph deals with sexual relations in the higher animals and man in the brutal stage. He looked upon the particular custom of "avoidance" in its inception, and as the earliest law to have been a vera causa of widest operation in primitive social evolution. The rigorous senility of this particular law in daily action is almost incredible. In New Caledonia, we are informed, all intercourse between a brother and sister by speech or sign is absolutely prohibited from a very early age. Mr. Lang, in acting the part of Editor of his cousin's MS., has not scrupled to take the rôle of severe critic. In the first 207 pages of this book Mr. Lang also presents an elaborate study of Totemism, and whilst attempting to elucidate and bring into uniformity the conflicting and confused terminology which has gathered round this "marriage" matter, and present the various views which have from time to time been put forward, he explains his own theory regarding totemism and exogamy with elaborate and almost wearsome detail, which to many minds will probably still be wanting in convincing force. The early history of the family as here portrayed, the evolution of the class system, the distribution of totems, phratries, etc. (a) "Social Origins." By Andrew Lang, M.A., LL.D. "Primal Law," By J. J. Atkinson. Pp. 311. London: Longmans, Green & Co. 1903.
and the origin of totem names and beliefs present many features of great interest and are certainly rich in suggestive thought. It is clear that these essays will take a prominent place alongside the works of McLennan, Keane, Crawley and others who have contributed to this difficult problem in the evolution of the human, and the numerous references given will render this volume of considerable service to the serious student of the subject.

MOORE’S FAMILY MEDICINE FOR INDIA. (a)

The manual under review is now so well known and so well received, that anything we can say regarding it seems somewhat superfluous. The volume opens with a chapter on domestic medicines and their modes of preparation and administration. This is followed by an alphabetical dictionary of diseases with their appropriate treatment. As this part of the volume is probably the one most referred to by the reader, we would point out that laymen can hardly be expected to treat cases of diptheria by “injections of antitoxin into the loose tissue of the chest,” nor in middle-earth dimness do we think anyone but a medical man should attempt puncture of the “drum.” In the valuable chapter on injuries and accidents we think no useful object is served by the table of distinctions between “convulsion,” “coma,” and “congestion,” nor can we agree with the author as to the wisdom of passing catheters by the laity. The chapters on pregnancy and labour, and on the management of infants, will prove most helpful, while that on the preservation of health should be read by everyone going to a warm climate. The appendix of prescriptions is very complete, but the formula are not always absolutely safe, if taken without medical supervision.

This edition, which has been carefully revised by Major Walsh, is rendered less bulky by an increase in the size of the page. We cannot, however, agree with the introduction of scientific terms which are scattered profusely throughout the volume. Even well-educated readers can derive no benefit from this widespread use of technical terms. These, however, are but minor flaws. As a whole, the work is one which has proved of great value to residents in India, and no one going to that country should fail to secure a copy of it. From previous acquaintance with this work, and from a fresh perusal of it, we can warmly commend the new edition to the notice of those whom it may more especially concern.

CLINICAL OBSTETRICS. (b)

We must congratulate Dr. Jardine on giving us such a readable volume as his “Clinical Obstetrics.” It owes its exegesis of illustration not to the scientific spirit displayed on almost every page of its contents. He has made good use of the exceptional opportunities which his position on the staff of the Glasgow Maternity for so many years has given him. He marks a new departure in writing a book on midwifery, inasmuch as he illustrates cases which, with few exceptions, were treated by himself the most important complications of pregnancy and labour. Special reference in this connection must be made to the chapters dealing with cardiac disease and with eclampsia. This new departure is a step in the right direction, and it fills a want which was long felt by the busy practitioner. The history of the cases is clearly given, and the treatment full in the important particulars.

The author’s enthusiasm in the cause of aseptic midwifery is not new, and he defends this volume to “those obstetricians who are endeavouring by aseptic methods to do for midwifery what has already been done for surgery.” Viewed from this standpoint, we would have expected at least one short chapter devoted to asepsis and to the steps necessary for controlling a labour on strict aseptic lines, considering the confusion that exists among qualified men as to what is really “asepsis,” a definition from the author as to his ideal, and how it could be obtained, would have been welcomed.

As to the treatment of eclampsia, he states “he has no hesitation in saying that the saline infusion method gave much better results than any other.” He claims that in the Glasgow Maternity Hospital the death-rate from eclampsia has been reduced nearly 50 per cent., taking cases just as they come. This is a remarkable statement, and it is interesting to see if it has been borne out by facts. He reports twenty-one cases, and we would naturally expect to find that the chief reliance was placed on the saline infusion. Yet what is the fact? In not a single case is the infusion the chief remedy. It is used in conjunction with other well-known remedies; this can best be shown by giving his treatment of a typical case. Case XI., p. 384—— “Epsom salts in large dose, tr. veratum viridi (10 min.) hypodermically; saline injection of 24 pints (acetate and chloride of sodium, 1 dr. each to the pint), hot pack, delivery accouchement force véloce, and of the saline infusion that cured the patient? The universal verdict would be “not proven.” The chapter on infant feeding is well done, and the instructions clearly given.

The Appendix consists of the statistics of thirty years’ work (1869 to 1898) in the outdoor and indoor departments of the Glasgow Maternity Hospital. It is very interesting reading. The tables might easily be left out; they are not models of clearness. On the use of the forceps its frequent application is remarkable (one in seven). It is, he states, applied much more frequently than formerly, and with the happiest results. “No woman is now allowed to linger in agony until she is exhausted. If, with good pains, the head is not making any progress after the second stage has lasted three hours in a multipara, or four in a primipara, we make it a rule to deliver.” The indications are clearly on humanitarian grounds. Dr. Jardine evidently thinks that this early application of the forceps, and, therefore, their more frequent use, is beneficial to the patient, and that it is abundantly justified by the results in the different decades, the first decade, of the 68 cases, 12 died (1 in 6), in the second, of the 307 cases, 8 died (1 in 38), and in the third, of the 650, 7 died (1 in 93). Is it not possible that aseptic methods might have something to say to these remarkable results? We think so.

LONDON IN THE EIGHTEENTH CENTURY. (a)

This fascinating work is a worthy monument to the patient industry and loving care of the late Sir Walter Besant. It will take a high place among the many and magnificent works already available which deal with the many-sided life and City features of our Metropolis, and it will become, we venture to prophesy, the authoritative work on the particular period of which it treats. Lady Besant tells us in an introductory Note that the work is issued “as my husband left it, and I am content to think that his labour has not been wholly in vain.” Besant undoubtedly knew the eighteenth century London as no other man of recent days, and in this attractive work there live and move before us the men and women of what we must now consider ancient days, in their work, pleasures, and occupations. It is impossible to do justice to this volume in the space to express adequately the wide extent of the research, the results of which are here so charmingly presented.

The work opens with a series of sketches of various important historical events, and here, perhaps, the

author shows to least advantage. But in his description of the City and its streets, and particularly of the manners and customs, society and amusements, Sir Walter Besant stands unrivalled.

Medical readers will find much of the greatest interest to them professionally, for a study of the past necessarily throws considerable light on the methods and manners of the present. A very interesting section deals with the discovery and art of medicine, of those far distant days. Bethlem Royal Hospital receives particular attention. Much of deep interest to the sanitarian and social reformer will be found in the pages devoted to a study of the daily life of the times, the habits of women, food and drink, coffee-houses and clubs, and the wells, spas, and pleasure gardens. Much new light is also thrown on matters connected with crime and the procedures of justice. Among the appendices a list of the unques-
ditions and casualties during 1770 are given, and we note 1,650 are the figures opposite small-pox.

This comprehensive work is one which is capable of affording an inexhaustible supply of material for thought and discussion. It should be kept within reach ready for reference, when the difficulties of the present throw us back on the problems of the past. It is a volume which not only every intelligent Londoner should study, but it should be within reach of every Englishman and Englishwoman who are desirous of knowing something of the men and women from whom they have sprung and into whose toils they have been privileged to enter. We particularly commend Sir Walter Besant's fascinating work to medical men.

GOULD'S BIOGRAPHIC CLINICS. (a)

The editor of "American Medicine" has written a truly strange book. He attempts to prove that the best course of the physical condition of the writer under review arose from some error of refraction. No doubt he brings forward evidence in support of the position he takes up, but we cannot allow the statement that "such diagnoses and such cures cannot be made by the methods in vogue in Europe" to pass unchallenged. He seems to think that only the "Philadelphia School of Ophthalmology" knows anything about the association of refractive errors with headaches and digestive diseases. Surely we do not require Americans to instruct us in a matter such as this.

Literary Notes and Gossip.

Mr. Heinemann is to publish in the autumn an English translation of Metchkoff's "Etudes sur la Nerveuse." The translation is to be edited and introduced by Dr. Chalmers Mitchell.

WANDERERS in search of mental recuperation and physical rejuvenescence would do well to consult The charming and elegantly illustrated new volume on "The Norfolk Broads," edited by Mr. William A. Dutt and published by Messrs. Methuen and Company.

The interesting Cavendish Lecture on "Disease of the Ascending Aorta," by Professor Clifford Allbutt, a part of which we publish this week in abstract, will be printed in full in the forthcoming July number of the West London Medical Journal.

The first number of the new quarterly, the British Journal of Inebriety, has just been printed and published by the Society for the Study of Inebriety by Messrs. Bailliere, Tindall and Cox. It contains much material of medical and sociological importance.

Dr. George H. R. Dabbs has just issued his interesting serial which has been appearing for some months in Vectis as an attractive book, "Down Grange." It is a fascinating story rich in medical interest. Dr. Dabbs is also contributing articles to the London Argus on matters relating to health and hygiene.

The ways of the astute American advertiser are past finding out. The Antikamnia Chemical Company have, however, adopted a useful method of drawing attention to their preparations. Dr. E. Curtis Hill, of the University of Denver, has prepared a most useful reference chart of "Diseases of the Nervous System," which affords in a condensed and convenient form a vast amount of information which cannot readily be obtained elsewhere. It has been the object of the editors to supply the necessary reference. A copy of this chart will be sent to any medical man on application to the English agents.

Medical News.

Typhoid Fever in Pisichire.

A formidable epidemic of typhoid fever is raging in the Lichore district, and the area of infection is still extending. So far upwards of 120 persons have been attacked, and considerable difficulty is being experienced in providing hospital accommodation for the victims. The outbreak is clearly traceable to the water supply, which had previously been in use, but nothing short of a drastic measure of this kind was required to stir up the authorities to their duty.

Compulsory notification of Pithitis.

The Sheffield Corporation have asked their powers to render the notification of consumption compulsory on medical practitioners, but as the Local Government Board are still hostile to the plan, the decision has been deferred until later.

A Luridious Mistake.

An ex-patient of the Bristol Royal Infirmary, dissatisfied with the treatment he had received at that institution, adopted the plan of cutting off one of his ears and sending it to the medical officer, with a covering letter couched in abusive terms. He was subsequently taken before a magistrate with a view to ascertaining his mental condition, but the result was a verdict of apparent sanity, and he was handed over to his relatives to be taken care of. Under ordinary circumstances self-mutilation would be accepted as prima facie evidence of insanity, but the Forest-of-Dean magistrates are apparently extra-particular.

Another Friendly Society Daybook.

The representatives of twenty-one friendly societies in the Hesn, Marpool and Langley districts had a meeting a few days ago to discuss the advance of four shillings per head claimed by the medical officers, and after a prolonged debate the question was adjourned in order that the medical side of the question might be brought forward.

The Barker Anatomical Price for 1904.

A Prize of £21 is offered for competition for "Dissection from behind of the Pneumogastric Nerves in the Thorax," by the Council of the Royal College of Surgeons, Ireland, and is open to any student whose name is on the anatomical class list of any school in the United Kingdom. The conditions under which the competition is to be carried out are:—(1) The preparation must be sent to the Curator of the Museums, Royal College of Surgeons, before March 31st, 1904, each being marked with a fictitious signature, and accompanied by a sealed envelope bearing outside the same signature and containing within (a) the full name of the competitor; (b) a declaration to the effect that the work of the preparation has been carried out by himself. The printed form of declaration can be obtained on application to the Curator. (2) The dissections are to be mounted in vessels fitted with glass covers, but the covers must not be sealed down. Earthenware basins and plaster of Paris settings are not compulsory if the specimens are better displayed and preserved by other means. (3) No
prize will be awarded unless sufficient merit be shown.

(4) Those competitors who enter dissections for which prizes are not awarded, but which show sufficient merit, may be refunded such amount of the cost of production as the examiners deem fit.

**Dublin Death Rate.**

The deaths registered during the week ending Saturday, June 29th, 1903, represent an annual rate of mortality of 23.4 in every 1,000 of the population. Twenty-seven deaths were caused by tuberculosis, 28 deaths were caused by diseases of the circulatory system, 32 deaths by diseases of the respiratory system, and 21 deaths from diseases of the nervous system; 47 infants died during the week, of whom 28 were under one year old. In 13 cases the deaths were uncertified, there having been no medical attendant during the last illness. Within the city the death rate was in the Summerhill district, 26.5 per 1,000; in the Lisburn street district, 36.4 per 1,000; in the South Earl Street district, 27.2 per 1,000; and in the Castle Street district 28.5 per 1,000.

**The Rontgen Society.**

**London County Council Epileptic Colony.**

The Duke of Fife, Lord Lieutenant of the County of London, who was accompanied by Princess Louise, Duchess of Fife, visited Epsom last week for the purpose of opening the epileptic colony which has been built on the Horton estate by the London County Council. The colony has been erected by the London County Council with the idea of the better housing, treatment and employment of the insane epileptics from the London County asylums. The plans of the buildings, which are estimated to cost £68,000, were made by Mr. W. C. Clifford Smith (engineer to the Asylums Committee) and Dr. C. H. Bond (who has been appointed medical superintendent at the colony). The colony stands on 112 acres of the Horton estate, on which the Manor Asylum with 700 females and the Horton Asylum with 2,000 patients have been erected by the County Council. The buildings comprise an administrative block and eight villas, in which provision is made for 262 males and 60 females.

**The North-East London Clinical Society.**

The annual general meeting of this society was held at the Tottenham Hospital, on July 2nd. At the conclusion of the purely business proceedings the meeting resolved itself into a garden party which assembled in the picturesque grounds of the hospital and which was well attended by the members and their lady friends.

**Medical Sickness and Accident Society.**

The usual meeting of the Executive Committee of the Medical Sickness Annuity and Life Assurance Society was held on the 26th ult at 429, Strand. London. A present Dr. de Havilland Hall, in the chair; Dr. St. Clair B. Shadwell, Dr. J. W. Hunt, Dr. F. S. Palmer, Mr. P. H. Symonds, Dr. F. J. Allan, Mr. F. S. Edwards, Dr. W. Knowles Shaw, Dr. J. Brierley James, Dr. Alfred S. Gubb, and Dr. J. B. Bell. The accounts presented showed the sickness experience of the society for this year was so far more favourable than in the first half of 1902.

The claims have been numerous, but for the most part of short duration, and the amount expended is less than in the same period of last year. The quinquennial valuation of the business of the society will be made at the end of the current year. The funds now amount to over £160,000, and a large portion of this will be found to be the necessary reserve for the future claims. The great economy however, with which the society has been conducted has led to a large saving and there is no reason to doubt that when every liability has been rigidly provided for a handsome surplus will be left to be applied as the members may determine. Prospectuses and all information on application to Mr. F. Addiscott, Secretary Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

**Poor-Law Matters in Parliament.**

Mr. Delany on Monday last called the attention of the Chief Secretary to the resolution of the Irish Medical Association declaring that no qualified practitioner should apply for or accept a dispensary appointment vacated by a doctor who had not received suitable superannuation, or at a lesser salary than £200 per annum, and declining to do duty for or meet in consultation any colleague who contravened the proposals contained in the resolution. And in a second question he asked whether, in case the salaries were raised, the Treasury recoupment would be proportionately increased. Mr. Wyndham said he was aware that such a resolution had been adopted, but the subject could not be discussed within the limits of a reply to a question. With reference to the second question, he said it was hypothetical, and that no definite reply could be given. The limits within which recoupment could be made were defined by Section VIII. of the Local Government Act, 1898, and Section vii. of the amending Act of last year.

**PASS LISTS.**

**Society of Apothecaries of London.**

The following candidates passed in surgery:—C. E. Adams (Sections I. and II.), W. E. Denniston (Sections I. and II.), H. B. Drake (Section II.), A. H. Faimer (Section I.), W. F. Jones (Section II.), W. Lovell (Sections I. and II.), W. A. Sugden, S. H. R. Welch (Section I.).

Medicine.—W. E. Denniston (Section II.), H. B. Drake (Section II.), N. S. Finzi (Sections I. and II.), W. F. Jones (Section II.), A. Wharton (Sections I. and II.).

Forensic Medicine.—T. E. Amyot, W. M. Emmer son, N. S. Finzi, W. F. Jones, A. Wharton.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—W. E. Denniston, H. B. Drake, W. M. Emmerson, N. S. Finzi, W. F. Jones, and W. A. Sugden.

The following candidates passed the Primary Examination, part I., July 1st and 2nd, 1903.

Chemistry.—J. M. Burke, C. J. Evans, J. N. Turner.

Materia Medica and Pharmacy.—L. W. Bradshaw, E. G. Brisco-Owen, R. P. Wylde.

The following passed the Primary Examination, Part II., June 29th, July 1st and 2nd, 1903.

Trinity College, Dublin.

NOTICES TO CORRESPONDENTS.

JULY 8, 1903.

Wigman, William Harper, M.B., B.S., M.R.C.S., Medical Officer for the Nos. 1 and 2 Districts by the South Molton (Devon) Board of Guardians.

Vacancies.

Royal College of Surgeons of England.—Examiner in Dental Surgery. Applications to the Secretary. (See adv.)

Bedford Hospital, Barnstable, Devon.—Resident House Surgeon. Salary £100, with board, lodging, and laundry. Applications, Ralph P. Pawsey, Hon. Secretary.

Royal Surrey County Hospital, Guildford.—Resident House Surgeon. Salary £100, board, residence, and laundry. Applications to the Hon. Secretary.

West Riding Asylum, Wadley, near Sheffield.—Fifth Assistant Medical Officer. Salary £100 per annum, with board, &c., Applications to the Medical Superintendent.

Brecon and Borough Infirmary.—Resident House Surgeon Salary £120 per annum, with furnished apartments, board, attendance, fire, and gas. Applications immediately to W. Powell Price, Secretary, & The Royal, Brecon, South Wales.

Willesden Urban District Council.—Medical Officer of Health. Salary £500 per annum. Applications to W. S. Ball, Clerk to the Council, Public Offices, Dyne Road, Kilburn, N.W.

Owens College, Manchester.—Junior Demonstrator in Physiology. Salary £100 per annum.

Ludlow, Hereford and Worcestershire.—Resident Surgeon. Salary £80, with board, lodging, and washing. Applications to the Hon. Secretary.

Camden District Lunatic Asylum.—Resident Medical Superintendent. Salary £300 per annum, and allowances valued at £150 per annum. Applications to John Keenan, Secretary Joint Committee, Stockport Infirmary.

Walthamstow Urban District Council.—Resident Medical Officer at their Isolation Hospital at Chingford. Salary £120 per annum, with board and lodging. Applications to C. Hudson Watson, Clerk of the Council, Town Hall, Walthamstow.

Ballinasloe Union.—Medical Officer for Ballinasloe Dispensary District. Salary £120 per annum, with registration and vaccination fees, &c. Applications to R. J. Gillen, Clerk, and Trinity College, Dublin.—Professorship of Chemistry. Applications to Benjamin Williamson, Registrar. (See adv.)

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JULY 8TH.

DERMATOLOGICAL SOCIETY OF LONDON (11, Chandos Street, Cavendish Square, W.,) 3.15 p.m. Mr. E. W. Roughton: Clinique. (Surgical.) 5.15 p.m. Mr. J. Berry: Hair-clip and Capel-palate.

THURSDAY, JULY 9TH.

BRITISH GYNECOLOGICAL SOCIETY (23, Albemarle Street, W.,) 8-9 a.m. Dr. H. D. Purefoy (Master of the Rotunda Hospital, Dublin): Notes on the Treatment of Cervical Ulcers. Discussion on the Lacerations of the Cervix Uteri and their Consequences (open by Prof. C. Taylor of Birmingham). The following, among others, are expected to take part: Dr. W. A. Angell, Dr. F. B. Staveley, Dr. Helme, Dr. Jellett, Mr. B. Jessett, Dr. G. K. Smith, Mr. B. Keith, Dr. Harper, Dr. Miller, Dr. D. W. McRae, Dr. J. A. Smith, Dr. Purvessey.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chorley Street, W.C.), 4-5 p.m. Mr. F. L. Winchcomb: Clinic. (Surgical.) 5.15 p.m. Mr. P. Stewart: Hyperia and its Diagnosis. MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASE OF THE LUNGS, Fitzroy Square, W., 3-4 p.m. Mr. J. Berry: The Surgical Treatment of Empyema. (Post-Graduate Course.)

FRIDAY, JULY 10TH.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chorley Street, W.C.), 4-5 p.m. Mr. J. Horne: Clinique (Thorax). 5.15 p.m. Mr. F. L. Wallis: Preparations, Methods, and After-Treatment in Operations.

Appointments.

Branigan, John, L.R.C.P., L.R.C.S.Edin., L.F.P.S.Eng., Coroner to North Kent.

Groves, Ernest William Hey, M.D., B.Sc., Lond., M.R.C.S., L.R.C.P. Lond., Assistant Surgeon to the Bristol General Hospital.

Kaye, Joseph, to the Superintendence of a new Asylum to be erected at Bangor, near Edinburgh.

Martin, C. F. R.S., of the University of Melbourne, Director of the Women's Medical Practitioner, Melbourne, Lady Gaitskell, S.W.

Robertson, John, M.D., M.R.C.S., Medical Officer of Health for Birming

Thornto, A. R. S., B.S., and Justice of the Peace.

Rowell, Thos., M.B., B.S., and Assistant Medical Officer at the Brentham Demonstration of Diseases of the Skin.

Ryle, Henry Greaville, B.A., M.B., Ch.B., and Honorary Surgeon to the British General Hospital.

Smyth, Henry James, L.R.C.P. Lond., M.R.C.S., Medical Officer for the No. 6 District, by the South Molton (Devon) Board of Guardians.

Smyth, Henry James, L.R.C.P. Lond., M.R.C.S., Medical Officer for the No. 16 District, by the South Molton (Devon) Board of Guardians.

Deaths.

Coates.—On July 5th, at Brocket House, Charles Henry Coates, M.R.C.S., L.R.C.P., Oxford Terrace, Middlesbrough, aged 82.

Manor.—On July 1st, at Cumberland House, Goldhawk Road, Shepherd’s Bush, Mary Drew, wife of Mr. J. A. Manor, aged 67.

Morrison.—On June 6th, at Bombay, suddenly, William Morrison, M.D., Ph.D., B.S., aged 80 years.

Barnes.—On July 2nd at Beauchamp Avenue, Leamington Spa, suddenly, Sarah, widow of Thomas Thurman, M.R.C.S., of Kidderminster, aged 84 years.

Original Communications.

A CASE OF "GRAPE-LIKE" SARCOMA OF THE CERVIX UTERI, FUNKATING INTO, AND INFLITRATING, THE WALLS OF THE Vagina, IN A CHILD TWELVE MONTHS OLD: EXTRIPATION OF UTERUS AND VAGINA. (a)

By J. H. CURTIS, B.S.Lond., F.R.C.S.Eng., Assistant Surgeon to the Royal Hospital for Women and Children, Waterloo Bridge Road, S.E.; Surgeon to the North-Eastern Hospital for Children, Hackney Road, N.E.

The child, aged 12 months, was brought to the Out-patient Department of the Royal Hospital for Children and Women, Waterloo Bridge Road, S.E., on January 28th, 1903, for "a large swelling in the abdomen and a discharge from the vagina, of about five or six weeks' duration."

Two months previous to being brought to the hospital she had had bronchitis. She had not seemed well since this time, when headache began to be suffered from, and the abdomen became swollen. The mother now noticed when the child cried that a "fump projected from the left side," and there was a good deal of discharge from the vagina.

The child "was always very white, and had never had a colour since birth."

Family History.—The patient was the second child, the first, a boy, dying when three weeks old. One miscarriage occurred after the birth of the patient. The labour in each case had been normal in every respect. No instruments were used. There were no other children. The parents, each aged 39, and married for two and a half years, were quite healthy. No family history of malignancy.

The condition of the child when seen in the Out-patient Department on the day of admission (January 28th, 1903) was as follows:—

She was well nourished, but pale and anaemic-looking.

There was a dirty-grey, purulent-looking vaginal discharge escaping from above the hymen, which, like the other parts bounding the vaginal outlet, was swollen, congested, and dusky grey in tint.

The discharge coming from above the hymen appeared as if escaping from an elongated cervix uteri, but subsequent observation makes it evident that the vaginal outlet must have been nearly occluded with fungating growths arising from the vaginal walls, the discharge issuing from between these little masses, to appear at the vulva.

Before this, however, as the child lay waiting for examination, the vaginal discharge was noticed to have formed quite a pool on the couch, so as to be obviously much more profuse than in the ordinary, so-called "strumous" vulvo-vaginitis.

The abdomen was seen to be distended and felt to be very tense, the girth at the most prominent part being seventeen inches. When disturbed for examination purposes the child cried, but did not otherwise seem to be in pain.

The abdomen was found to be occupied with a smooth, rounded, tense swelling arising from the pelvis, and extending from the symphysis pubis to midway between the umbilicus and xiphisternum, and then passing rather more towards the left than the right side. The fingers could just be inserted between the top of the swelling and the left costal margin. On the right side the tumour reached nearly to the right linea semilunaris.

The right flank was resonant on percussion, and free from swelling. The tumour in the middle line, and extending well into the left flank, was dull on percussion.

The constant crying of the child during attempts at examination greatly interfering with accurate investigation, it was admitted for further observation, with a temperature of 99.7° F.

On the day after admission (January 29th) the abdomen became more tense, and the child cried a good deal through the day. The bowels acted, the stools being natural.

The temperature fell from 99.7° to 97°. The child looked somewhat livid and dusky; there was evidently some respiratory embarrassment, which increased during the evening, the pulse being rapid and rather feeble.

The condition of collapse appearing to demand exploration, the writer was sent for, and at midnight, January 29th, median laparotomy was performed.

Operation, January 29th, 1903 (midnight).—The peritoneal cavity was entered through a median incision extending from the umbilicus to a point one inch above the symphysis pubis, and subsequently enlarged in an upward direction.

The tumour, where exposed, was almost spherical, covered for the most part with smooth peritoneum, and seen to be arising from the pelvis. Sprunging from the anterior surface, a short distance below its rounded upper extremity, were seen the congested fundus uteri and uterine appendages, below which was a firm band of adhesions passing forward to the anterior parietes.

Below this the bladder was visible, bound down to the front of the swelling. With some difficulty the two ureters, firmly incorporated with the antero-lateral aspects of the tumour, were discovered passing forward to enter the base of the bladder. A circular, raised, button-like swelling, flattened and congested on its surface, crowned the summit of the main swelling, i.e., behind the uterus itself, and slightly to the right of the middle line. This appears to have resulted from the growth beginning to fungate outwards, through the investing peristium, with formation of adhesions to the neighbouring structures. At this stage, and, indeed, until closer examination of the tumour after removal, its exact origin was not clear, but the condition appeared to be due to malignant disease of the uterus—probably sarcoma.

Complete removal of the tumour, wherever originating, was obviously the only possible treatment.

Holding aside the intestines, the bladder was first

(a) A Paper read before the Obstetrical Society of London, July 1st, 1903.
carefully isolated from the front of the tumour, to which it was firmly adherent; the ureters were then, with considerable difficulty, enucleated from their position at the junction of the smooth peritoneal-covered upper rounded part of the tumour with the roughened, somewhat indistinctly rounded, slightly lobulated, surface described above.

The bladder and ureters being thus freed, the connections of the uterine appendages and the lateral aspects of the tumour below these, with the sides of the pelvis, were severed, securing the vessels as they came into view, the haemorrhage being unimportant.

At its lower extremity the thin-walled, stretched vagina proved to be very friable, giving way with very little traction when the tumour was completely isolated in other directions.

The child's collapsed condition by this time prevented very close examination of the pelvis, but so far as could be ascertained, all obvious disease had been removed. The laparotomy wound was rapidly closed, and the usual restoratives administered (hot water and brandy enema, strychnine, &c.). Brandy, ½, was ordered with each of the three-hourly feeds of milk and barley-water. Small doses of opium were also ordered.

When seen on the following morning (January 30th) the general condition had greatly improved. The pulse was stronger, the frequency being 148-152 per minute, the respiration rate being 32-36. The temperature, F. on the day of admission (January 28th), was 97° F. on the day of the operation, and 99-100° F. during the succeeding day. The child was quite quiet, but free from any discomfort, and active, playing with toys; but its passive conditionings of varying size. Some of the "cysts" are rather less translucent than others, and some show areas of dirty chocolate tint, which, from microscopic evidence, appear to be the result of haemorrhages. The resemblance of this mass of "cysts" to a bunch of grapes, or a hydatidiform mole, is obvious.

The "cysts," on section, are of semi-solid consistence, the appearance presented being closely comparable with a myxomatous tumour. The "cysts" measured as much as 3 centimetres (1½ inches) in diameter.

**Measurements.**—The length of the exposed portion of the uterus was: Posteriorly, 2 cms. (⅛ inch); anteriorly, ½ cm. (⅛ inch); omitting the uterus itself, the length of the tumour from its apex along its posterior wall to the line of reflection of the peritoneum of the vesical reflection of the bladder is 2½ cm. (⅛ inch); and anteriorly from below the insertion of the uterus, to the line of reflected peritoneum was 6 cms. (2½ inches); the greatest girth of the mass, 294 cms. (11½ inches).

**Microscopic Report.**

1. In a portion of one of the cysts of the cervix uteri and adjacent form of the vagina, removed for examination, the changes appear to be confined almost entirely to the stroma. There are about the usual number of cervical glands, lined by a single layer of epithelial cells. Apart from considerable dilatation, the glands present a normal appearance. Their presence affords no justification for the title of adenoma (myxoma)-sarcoma adopted by some writers (Mundé, Wincze).

2. Sections of the "grape-like" growths presented the following striking features:—(4.) Large columnar
epithelial cells with large oval nuclei form the outer layer, which was readily detached, unfortunately, during the handling incidental to fixation, &c. The layer beneath consists of small flattened cells arranged regularly, almost end to end. Still deeper are seen other cells, with large round or ovoid nuclei, scattered irregularly in the stroma. (ii.) A remarkable number of cells, flattened and engorged blood-vessels are seen throughout the section, lying in (iii.) an obviously oedematous, finely reticular stroma, containing large and medium-sized spindle, round, and ovoid cells, the spindle cells containing large ovoid-shaped nuclei, and the nuclei in the round and polygonal cells being in a very active state of proliferation. No myxomatous tissue is evident. The "grape-like" growth may therefore be briefly described as an oedematous, mixed spindle and round-celled sarcoma.

3. Sections of vaginal wall infiltrated with growth, forming a projection on its inner surface.—The growth is seen to be arranged infinger-like processes, covered with stratified epithelium. The appearance of round and spindle cells seen elsewhere is reproduced here, the oedematous infiltration separating the cells being, however, less marked. Giant-cells are present here and there in the papillae.

4. Sections of the secondary deposit in, or near, the left iliac lymphatic gland.—The common iliac artery near its division lies embedded in this mass of growth. Secondary deposits, artery fillets, being mass of cells as large and very numerous leucocytes are seen entangled in the fibrin. The growth itself, around, consists of spindle cells and round cells, the bodies of the round cells being very degenerate, the delicate reticulum forming the stroma being thereby rendered very obvious.

Cases of cervical sarcoma, according to Whitridge Williams, may be divided into two groups, one including only several varieties; the other, easily distinguishable, being known as "grape-like" sarcoma (das trauhige Sarcoma), a non-committal term first applied in 1862 by Pfannenstiel, though Spiegelberg, in 1879, was the first to draw attention to this group, recording one case in 1877, another in 1880, and referring to one such case of his own which had been reported by Kunert as far back as 1874.

Numerous descriptive titles have been applied to this group, and are indicated in the literature quoted at the end of this paper. For these references and much information I must express my great indebtedness to J. Whitridge Williams's exhaustive monograph, entitled "Contributions to the Pathology and Histo-genesis of Sarcoma of the Uterus." (a)

Up to 1804, eleven cases of "grape-like" sarcoma appear to have been recorded, the twelfth, Klein-Wachs's case, alluded to by Pfannenstiel in 1862, being probably an angio-sarcoma, and not really forming a member of this group. Emmet's case, in a girl, at 15, reported (b) in 1902, was thought to be the sixteenth on record. The present case, therefore, appears to be the seventeenth reported.

Lewers (c) says he has not met with such a case himself.

Spiegelberg's description of his first case, macroscopically and microscopically (given in Williams' monograph), corresponds so closely with what was found in the present case that its reproduction here may therefore be pardoned.

Spiegelberg in 1867 described a case in a seventeen-year old girl in whom he found the anterior lip of the cervix thickened and enlarged. It was covered on its margin as well as on its surface by a group of oval, yellowish-brown outgrowths, one or two centimetres long, which looked like transparent cysts. These were readily crushed when touched, and contained a thick, sticky fluid. The anterior lip of the cervix was removed with scissors. The vagina later returned with the entire vagina filled by a growth, which resembled a hydatidiform mole in appearance, and also arose from the anterior lip by numerous strong thread-like pedicles. The mass was again removed, and rapidly recurred, eventually the entire uterus was removed, and the patient died later from cachexia.

The tumours were examined by Weigert, who found that the cyst-like masses were covered by a single layer of cylindrical epithelium, and their interior composed of large, round, spindle-shaped, and fibroblastic cells, which were separated from one another by clear spaces traversed by fine threads. In these spaces lymph corpuscles were found, and between the cells and within the spaces. In the more compact portions of the growth, and in the pedicles of the cysts, large cells without the clear ground substance were seen. The growth at first suggested a myxomatous sarcoma, but fresh specimens failed to give the characteristic mucin reaction with acetic acid. Spiegelberg accordingly concluded that the appearance was due to oedema, the result of stasis in the numerous lymph sinuses of the cervix, and suggested for it the above-mentioned name.

"Pfannenstiel, in 1892, agreed with the majority of observers that the growths in question were not myxomatous or myxo-sarcomata, and believed with Spiegelberg and Weigert that they were infiltrated with lymph, and could be designated with propriety as 'sarcoma lymphangiecisticum et hydro-picum. He showed conclusively that the growth in his case arose from superficial papillary processes, and that the cervical mucous membrane, to whose papillary structure it owed its peculiar form; and in all probability that it was connected in its origin with proliferative changes, which he observed about the lymphatics and blood-vessels." (Williams.)

Bland-Sutton and Giles (a) refer to Perrin's well-known case, and reproduce two illustrations. They say, "Perrin describes a very remarkable example of sarcoma which involved the vaginal portion of the cervix.

It had a racemose appearance, the grape-like bodies being composed of cells, some of which were ovoid shaped; others were typical epidermises, many of them presenting a cross striation indistinguishable from that of a striped muscle. In the basal parts of the tumour gland-like spaces existed lined with cylindrical or with cubical epithelium. (These were derived from the glands in the cervical endometrium.)

"After removal this tumour quickly recurred. It was removed a second time, but reappeared, and rapidly infiltrated the uterus, forming a large mass. Death was speedy.

"On microscopic examination of the recurrent tumour no striated spindles were found, and the tumour had the characters of a simple spindle-celled sarcoma."

The great majority of the cases collected by Whitridge Williams occurred in persons under twenty years of age, or past the menopause, and only three in the intermediate period. Smith's case occurred at three and a half years of age, Ashfield's at fifteen years; so that it would appear that the case now reported, at 1 year, is the youngest so far met with.

"This age distribution enables one to distinguish 'grape-like' sarcoma of the cervix from the simple-celled carcinoma of the cervix, exceedingly rare before the twentieth year, and occurring most frequently just before the menopause. A positive diagnosis between squamous carcinoma of the cervix and the other groups of cervical sarcomata referred to cannot be made, according to Cullen (b) without a microscopic examination, records of cases showing that even then it is at times impossible to reach a clear diagnosis.

Williams adds the interesting information that in all the cases he collected, death occurred from regionary metastases, with the exception of Byford's patient, of whom it is only stated that she recovered from the operation. True metastases were rare, however, only in the cases of Kunert and Kuntz.

Emmet's patient died a year after the first operation,

(a) Amer. Jour. of Obst., Vol. XXIX, 1904.
(b) Jour. of Obst., March, 1902.
(c) '* Cancer of the Uterus,* 1902.
at which a deep wedge-shaped piece of the posterior lip of the cervix, including the growth, was cut away with scissors. At the second operation, seven months later, high amputation of the cervix was performed, and the mass now encircling the cervix, and filling up the vagina with "grape-like" growths, removed. Death occurred in four months, and death a month later, the growth being described as a spindle-celled sarcoma.

It is clear that the only hope lies in early diagnosis and complete hysterectomy.

The Cavendish Lecture on **DISEASE OF THE ASCENDING AORTA.**

By T. Clifford Allbutt, M.D., LL.D., F.R.S., F.R.C.P.

Regius Professor of Physic in the University of Cambridge.

(ABSTRACT.)

(Concluded from page 23.)

All diseases of the aorta, if they pass into chronic states, tend to atheroma. Syphilitic arteritis, if occasionally to be recognized, its earliest manifestations, becomes ultimately atheromatous, but leads even more decidedly to altered diameter, bossing, scarring, wrinkling and puckering of the vessel. This may happen at a very considerable degree of degeneration of the intima and adventitia, with some increasing degeneration of the media, so that proper suggest a syphilitic process. The age of the patient may also be significant. A rarely recorded but definite kind of syphilitic aortitis is a quite distinct mesenteric, favouring the occurrence of aneurysm.

The chemical changes of atheroma, according to Gueret, consist of a fall in nitrogen and a large rise in ash. Fat is most abundant in the intermedia phases, as we might expect. The increase in ash depends upon the lime; if the ash of dried atheromatous aortic substance rise, as it may, even to six-fold of the normal standard, the lime of this ash would rise to twenty-fold.

The coronary arteries, or at any rate their orifices, rarely escape in atheroma of the ascending aorta; if the process be slow, complete obliteration of these orifices is consistent with a thoroughly sound and powerful heart muscle, one which may make up by increased velocity for the narrowest constriction of the aortic orifice.

If the symptoms some are, as I have said, equivocal, and of these are headache—of various meaning, no doubt—vertigo and dyspnea of a kind. Of the cause of the vertigo, an early symptom which is often notable and even alarming, I must leave myself to surmise of a reflex mechanism. Concerning the dyspnea, which is to be discriminated from that directly to heart or lung affection, or to pressure effects, there can only be the surmise of the symptoms independently of the pain, of which I shall presently speak, and in its mode and caprice nearly resembles spasmodic asthma; but it is without the critical relief by expektoration, without the spirals of Curschmann, and, if a surmise, without the "eosinophilia." It is a light and retarded breathing, independent of exertion—the panting of a dilated heart. These three symptoms are significant of acute phases of aortitis. Pressure symptoms are my first consideration in syncope, as of the arch than is usually supposed, and by no means dictate aneurysm or other tumour.

In the later stages of Hodgson's disease pressure symptoms are usually perceptible, and in some cases quite dominant. Among such symptoms I have witnessed spasmodic closure of the glottis, in attacks so persistent and terrific as to call for chloroform, or even for tracheotomy; minor degrees of distortion of some branches of the lower vena cava has been noticed; and though this last is mere dilatation, and is rarely perceptible. Here it is convenient to allude, for I can do no more, to acute pulmonary redema, which is said to occur in disease of the aorta. It may be said, it occurs after its fashion under other obscure conditions; but more often it appears in moderate degrees, which if perilous, may be transient. A sudden distress leads to examination of the back of the chest, where in a larger or smaller gathering of crepitations is discernible for a few hours, or for a day or two, then gradually disappears. I have never witnessed this event in aortic disease as distinguished from general arterio-sclerosis, and I am not convinced of its occurrence apart from the latter condition. I may remark by the way that emphysema of the lungs is a well-known accompaniment of atheroma of the aorta, and may even take some place among its characteristics in aural atheroma.

That pain, and pain having peculiar and even appalling features, arises in disease of the aortic area, that is, of the first portion of the ascending aorta. Perhaps of the aortic orifice, is in one sense, and in another sense, however, it is misconceived. In the examination of cases of angina pectoris our eyes are too exclusively fixed upon the coronary arteries; the orifices and the tunics of these vessels are scanned for atheroma, and if atheroma be found—in such disease of this area they hardly escape—the pain is held to be explained, and no fresh thought is given to the matter. Yet the truth is that this pain, which in a smaller or less intense degree are caused in this portion of the artery, is due neither to coronary artery nor to heart, but to the disease of the base of the aorta, with
which coronary atheroma is commonly associated. Nor is it the ascending arch, even when acute, is often unattended with pain; in the aortitis of the exanthema, pain is frequently, in some of them generally, absent. In the aortitis of small-pox, or of typhoid fever, we detect the signs of its existence by physical signs. In the aortitis of influenza, of rheumatism, of syphilis, pain occurs: but probably in a small minority of cases. In atheroma of the area, again, pain occurs in a small—minuscule—very small—microscopical— very small—minute—very minute—case, it is then, no direct relation between the cause, the acuteness or the range of the aortitis and severity of pain; the intensity of the pain in certain cases must be explicable by some other element, by some other precursory thing, by the depth of its penetration, or possibly of its pressure on some adjacent organ or tissue. We may guess that the relation of the fibrous to the nervous tissues of and about the ascending aorta may be the determining factor of pain in inflammation, acute or chronic, of these parts. Suffice it now to repeat that pain, and pain having peculiar and even appalling features, arises in disease of the root of the aorta. The features are: operation or fracture of the sternum at the junction of the first and second thirds of the bone, and sense of constriction or oppression, as if the chest were in a vice, or the breast-bone crushed inwards by an iron bar; I speak, of course, of the patient's subjective sense. Pain may come in any degree, from a momentary sense of tightness about the upper sternum, aroused by exertion and stopped at once by rest, to sheer torture. And, in a case of aortic aneurysm, the pain proceeds from the visceral origin into sections of the brachial plexus, in the first instance, of the left side, but occasionally of the right also—very rarely of the right alone; and not of the brachial plexus only, but in lesser nerves, of the intercostal nerves of the left side also. I am accustomed to divide the courses of this aortic pain by the terms I apply to spreading zones of other pains, spasms and perturbations—namely, into the primitive area and into the secondary areas. The latter disease is rare; the area being for the most part of compound reference, which are invaded successively as the irritation, or the instability of the system, increases. As in a child, a cutting tooth may have a primitive area of pain in the parts about it, and thence may force a sphere after sphere of inhibition to vomiting and even to general convulsions, so a corrosive action at the root of the aorta may cause a pain in the stomach only, or, forcing successive spheres of inhibition, may drive it to the shoulder, to the inner condyle of the humerus, to the ring and little finger, and yet again to the third, the fifth and other intercostal nerves. And this, it seems, is the case in the majority of cases. We are apt to attribute its origin to the heart.

Of a particular kind of dyspnoea in the primitive reflex zone of aortitis I have already spoken; in angina pectoris a dyspnoea may arise; but if infrequently this feature occurs, it is not characteristic, usually the patient is held in a deathly stillness. When dyspnoea accompanies angina pectoris either the heart is diseased already and is gravely depressed by the effects of the pain, as it violates yet another sphere of inhibition, that, namely, of the heart. As irritation of the central end of a divided sciatic nerve in an animal, as the torture of a gall-stone driven through the duct in man, forcing the inhibition of the heart, may slow auricle and ventricle, or even arrest them in death; so the pain of a diseased aorta—angina pectoris—having invaded the outer and inner bailey, may force the very keep of life, and may arrest the heart in fatal syncope. Herein lies the perilousness of aortic pain to him whose heart is frail; to him, let us say, whose coronary arteries are occluded, and which by the consequence—those cardiac muscle is in decay. To one thus unstable at the centre angina pectoris is often a mortal agony; to one whose heart is sound and perfect, or relatively sound and perfect, such pain is of no account. In dilated, in acute aortitis, as in other agoniising visceral pains, even a sound may be arrested in death. Perhaps if the heart be frail the vagus steps in sooner to protect it, perhaps it is forced more blindly into excessive function as we now know is the case in death under chloroform. In the two instances the causes differ, but the mechanism of death is identical, and artificial respiration should be applied in aortic cases in the same way.

As a prophylactic bromide of ethyl might be useful, as suggested by Waller in the administration of chloroform.

In not a few cases, however, the heart does not quail, and the sense and apprehension of death are less frequent, less terrible, or often, indeed, absent. Elderly patients, the subjects of angina pectoris, do, indeed, die suddenly of cardiac failure, in an attack as it is said, of angina, an anginal attack; no doubt of disease of the perishing organ stops—as we say—of itself. Some stir of flatulence, some nervous hitch—such as that which makes us twitch or bound in our sleep—and the worn-out heart answers to time no more. Such a death is apt to occur likewise in the case of aortic insufficiency in a heart whose muscle may not be gravely unsound. That the apprehension of death is not due to mere cerebral anaemia, but to some secret omen within the cardiac mechanism, seems by the experience of the patients of "Stokes-Adams disease," in whom the approach of insensibility and convulsion is a moment, as I have been told by one of them, of no unpleasant lethargy.

When a chronic aortitis, pursuing for the greater part a painless course, is broken by terms of acute activity, angina pectoris may come and go with such vicissitudes as to have seemed to the patient the eruption of angina, even in acuter phases of chronic disease, which departed for good. In acuter aortitis its departure is perhaps the rule, the condition being that the heart is soon in keener cases along the lines of physical signs in aortitis there is no great lack, if we will but look for them; unfortunately they are for the most part signs of the fully established disease, of chronic aortitis and atheroma. The earliest stage of the disease is one of indistinctness, to say the least, except in its acutest modes. It is understood that in this address I confine myself to disease of the ascending arch, without aneurysm, without polyarteritis, and without regard to general arteriosclerosis.

To sight and touch acute aortitis scarcely betrays itself; some throbbing in the neck—if such there be—may be due to some far less grievous cause. In chronic aortitis we have a somewhat more practical kind of evidence. Even in the aspect of persons between twenty-five and forty years of age a quality of deterioration is to be noted; especially if, as is the outcome in such cases, it lies at the root of the disease. At all ages, then, signs of premature senility are prone to appear; in some persons the face is pinched, worn, and perhaps furrowed by the anxieties of pain or other disablement, and the complexion, whether the case be syphilitic or not, is white or sallow, and the hair thin and grey. In other persons—stout, elderly men of full habit, long subject to high arterial pressures—the rubicund face takes a venous hue; and under its rather dewy, dark surface a bilious tint is to be noted, especially about the temples and cheek-bones. On closer approach the veins of the neck may appear too prominent, and even pulsate. The superficial veins about the face, neck and chest may be dilated, and the neck and face puffy. Arterial pulsation also may be conspicuous in the same region, although aortic insufficiency, Graves' disease and chlorosis be out of the question. The hand, now laid upon the upper chest, may perceive a thrill, as if the walls of the arteries had become unduly and irregularly rigid, or as if eddies were formed in dilated channels. The arch is often to be felt by the finger-tip in the supra-sternal notch, especially if the patient be thin, and will bend his head forwards. Sometimes, however, this pulsation is remarkable by its absence. In an advanced case a quick observer may even estimate some diminution of the pressure of the carotids; and if so he will note the point as possibly significant of some incrustation about the
orifice of one of them. The dome of the innominate may be visible, or palpable; and, if the patient be made to depress the point of the right shoulder, the right subclavian, as M. Faure has told us, may be palpable, or even visible above the collar-bone. This sign I had observed for myself, and in some cases have seen the subclavian rising even an inch above the bone; so that at one time I was too sanguine of the value of the test, and could not know whether I was observing some reason or another, even in an advanced case. The sign has a positive but not a negative value. The orifices of the arteries which take their rise from the thoracic arches, are, as we remember, especially noxious to the stresses of the blood current; they incur minute lesions upon which atheromatous patches may so gather as to narrow them; a quick eye may not consequent differences in the diastolic volume of pairs of arteries, and one may find the radial pulses to be an unequal pair. Or, again, if atheroma have invaded a pair of orifices, the pulses of the corresponding arteries may be judged as falling alike under the general standard of pressure. Of such a bilateral defect I have felt assured in more than one patient; I am thinking of one case of equal defect in the carotids, and of another of equal defect in the brachials. That the failure, by the way, that I exclude from consideration all cases in which peripheral arterial disease obviously interfered.

More trustworthy evidence of elongation of the ascending aorta than may be afforded by the subclavians was pointed out by Traube, and verified by Edgren and myself; namely, mobility of the heart's apex. Undue and even extreme mobility of the heart is seen in other maladies, as, for example, in neurasthenia; but by other features this and such maladies can be excluded. We turn the patient, who is lying upon his back, on the left side, and, as he turns, we find the heart's apex swinging outwards also, until it may make itself perceptible far outside its pre-existent position—the time the left parasternal line of absolute dulness moves to the left, but not to the same degree. Assuming, as for the moment I must, that the heart's apex occupies its normal place, it may fall away even to the anterior axillary line. We may be satisfied of undue mobility even in a large heart; or again, we may attribute some extrusion of the apex to elongation of the aorta rather than to ventricular hypertrophy. But such nice points as these in individual cases, cannot be reduced to rule. As in aortic aneurism, cardiac hypertrophy has no necessary association with atheroma of the aorta. Under the head of inspection I should include radioscopic; by its means dilatation of the aorta can be seen in larger degrees. The test is useful rather to exclude atheroma of the arch; or possibly to betray the presence of one of the small aneurysms which are apt to arise at the root of the aorta, and occasionally give rise to angina pectoris and to some of the other symptoms I have considered with it.

Percussion is the most valuable single method we have of detecting dilatation of the aorta, whether the dilatation is a temporary and occult variable, as in acute aortitis, or static, as in chronic cases. According to the degree of dilatation, a dull area may be delineated occupying an area including the manubrium sterni, and extending thence towards the second space and the third cartilage on the left. As the upper part of this dull area extends from the base of the breastbone in a segment of a circle to the right, it has been likened to the crest of a fireman's helmet, a comparison made, I believe, by Pottain, who did much to verify and to affirm this change, and, as far as my experience goes, with good reason. The sign is invariable, and is generally trustworthy, if we bear in mind the common occurrence of emphysema in these atheromatous persons. The area, however, is not distinct all the time, but is in a auricular, which lies below it. Pottain warns us, and his warning is good for all cardiovascular percussions, to delineate the area of dulness not by advancing outwards from the body of it, but approaching all segments of its circumference on convergent lines from the surrounding resonance.

The signs of auscultation are inconstant and equivocal; moreover, in my paper it is difficult to divide the evidence of mere aortic from that of cardiac disease. In mere aortic disease, for example, we may hear no systolic murmur, even in an advanced case we may not; on the other hand, a systolic murmur may be audible, but whether it be of aortic or one of the fluid veins in a dilated arch it may be difficult to say. In the latter case it may be widely propagated into the arteries, and loud over the descending arch behind; in the former case it is confined especially to the left subclavian, and may present the roulement presystolique de Lemoine, a phenomenon which always reminds me of Quain and Morison's experiments on the generation of the first sound in such a case.

A certain quality of the second sound may be of cardinal value; unfortunately it is often far from constant. This quality may be reinforced by high arterial pressure, but is not by any means dependent upon it. It is a clang, which has been so aptly compared by Pottain to the tap of the tabourka—a drum made of a skin tightly stretched upon an earthen pot—that I hope this word will be imported into England also. This may occur in mere aortic stenosis I cannot say—these cases are not frequent; but it was not present in four such cases of my own experience. And it tells us not exactly the state of the aorta, but of a state of the valve often associated with disease of the aorta. The message from the aorta to us; indeed, the aorta remaining the same, it often vanes or alters, not with variation of blood pressure, but as the valve by some pathological change alters its thickness, or in relation to the other parts of the instrument. Yet in spite of all these contingencies, the tabourka sound tells an unmistakable tale. And, assuredly, even its alterations may often enliven rather than obscure our knowledge of a particular case. That a murmur of it might suggest progressive disease at the base I have said; if, on the other hand, to the stethoscope placed in the jugular fossa it persists, while pressure is falling, with perhaps some arhythmia, some acceleration, or some retardation of the pulse rate; or, again, if, while the aorta is heaving and carotids are throbbing, yet the distal pulses of the dorsales pedis or the anterior tibials are feeble, we shall apprehend coronary disease and cardiac default.

A murmur, even if systolic only, in my opinion generally means valvular disease, spreading, it may flow from above. Relative aortic insufficiency I still think is clinically rare, in spite of museum samples. When it occurs, however, I admit that the regurgitant murmur is often so faint, so distant, so inconstant, that, unless while the patient holds his breath all accessible areas of such a sound may be sought, it may well escape the physician who is not on his guard. That a murmur may be caused during cardiac diastole by recurrent fluid veins within the dilated arch itself I will not deny, but am not ready to admit. Of one more physical sign, one sometimes of cardinal importance, I have yet to speak—the chafing sound of a dry, basic pericarditis, occasionally associated with aorticaneurism. Percardioscopy the aorta may arise, I suspect, in two modes: first from the outside, invading the circumference of the aorta embraced by it; secondly, from within, whence aortitis penetrates to the investing pericardium. The former cases are usually rheumatic; but they may come of other infections, of Bright's disease and some other maladies. Now, whether the pericarditis be of inner or outer origin, it is so frequently attended by angina pectoris that a proper appreciation of her conditions may be, I repeat, of cardinal importance. That the angina pectoris in these cases is independent of coronary disease has been demonstrated by Pawinski. Let it not be supposed that pericardial angina is alien from a suppositious coronary angina in respect of fatalitly, it is mere to put a sound than a diseased heart in check is true; but I have seen in more than one such case, and more than once in a single case, the pathologische sim-
The administration of anaesthetics in operations performed for the cure or relief of rectal diseases, of which the more commonly seen requiring operation are piles, prolapse, ischio-rectal abscess, fistula, fissure, polypi, stricture and malignant growths, vary in conditions sufficiently from those for the ordinary run of operations to justify their special consideration. First, the majority of the patients are of one or two types, being either strong, full-blooded, and free living, or weak or sickly, and must be operated on at a very sensitive, necessitating a depth of anaesthesia that will prevent spasm or movement of the limbs during the painful operative proceedings began in some cases by forcible and paralyzing dilatation of the sphincter and the rectum being the seat of the disease. The patient is always of necessity placed for operation in one or other of several positions, differing from the ordinary or dorsal position, during operation. At St. Mark's Hospital for Rectal Diseases it is customary in pile cases to have the patient lying on the right side and slightly inclined towards the prone position, with the thighs and knees somewhat flexed. This position is also used for right fistula, right ischio-rectal abscess, and for fissure. For left fistula, the corresponding position with the patient on the left side. For horse-shoe fistula, one or other of the above positions or the lithotomy position maintained by the use of Clover's pouch. Actually, this position is chosen as the most suitable for operation for piles. The side and prone positions may appear awkward for the anæsthesiologist, but the tongue does not fail back, and the secretions tend to flow towards the air-way, which can be excluded by self or assistant. In the various operations, including Kraske's, for excision of the rectum, one of the above positions is adopted, or the patient may be prone, with the thighs hanging from the end of the table, the knees supported on a chair. The trussed-up position, with the use of Clover's crutch, especially with stout and short-necked people, may cause embarrassment owing to congestion of the head and neck, swelling of the mucous membrane of the nose and pharynx, and accumulation of secretion. A low pillow, or none at all, is needed, and the head should be kept on one side. Possibly the pressure of the band on the nerves of the neck may sometimes adversely influence the respiration and circulation. Fourth, in the preparation of the patient, the fact that the bowels are advantageously confined for three days after the operation will suggest that special attention should be directed to clearing them out before. After describing the preparatory, as followed at St. Mark's Hospital, he said sickness in the theatre or in the ward associated with the anaesthetic very seldom occurred. In different types of operations complications in the lower abdomen are far more serious than in the upper. The dangers of special kinds are likely to arise, and these may be anticipated and met more easily, generally speaking, when ether is administered than when chloroform is given. In fact, the patient is in no danger of extreme congestion, swelling of the mucous membrane, and excessive secretion, a change from ether to chloroform will lead to a disappearance of those conditions, and anaesthesia may be easily established and maintained, much less chloroform being necessary after the preliminary ether than would otherwise be required. It is easier to administer that sequence than chloroform throughout to such a patient. In his Introductory Address, entitled "The Field of View of the Anæsthesiologist," Mr. Lloyd entered into the physiology of the nervous, the respiratory, and the circulatory systems in various conditions associated with the administration of anaesthetics. During an operation the quantity of blood in the patient varies for practical purposes, not only by reason of the haemorrhage that is taking place, but also with the situation of the remaining blood and consequent supply of blood to the vital organs. Though, as already remarked, some patients are strong and full-blooded, and in them limited hemorrhage facilitates the administration, complications such as congestion, swelling, excessive secretion, &c., being relieved and a smaller supply of anaesthetic, yet if the hemorrhage is excessive the circulation and respiration become feeble, even alarming; and on one occasion a big, flabby woman, about 65 years, who had uncontrollable intra-abdominal hemorrhage

It is easier to administer that sequence than chloroform throughout to such a patient. In his Introductory Address, entitled "The Field of View of the Anæsthesiologist," Mr. Lloyd entered into the physiology of the nervous, the respiratory, and the circulatory systems in various conditions associated with the administration of anaesthetics. During an operation the quantity of blood in the patient varies for practical purposes, not only by reason of the haemorrhage that is taking place, but also with the situation of the remaining blood and consequent supply of blood to the vital organs. Though, as already remarked, some patients are strong and full-blooded, and in them limited hemorrhage facilitates the administration, complications such as congestion, swelling, excessive secretion, &c., being relieved and a smaller supply of anaesthetic, yet if the hemorrhage is excessive the circulation and respiration become feeble, even alarming; and on one occasion a big, flabby woman, about 65 years, who had uncontrollable intra-abdominal hemorrhage
during an operation, gradually failed in that way and died on the table forty minutes after the discontinuance of the ether, although the hemorrhage had been stopped, saline solution injected, brandy administered, and strychnine hypodermically introduced. After referring to ordinary agreements the patient, the administration of an anesthetic, he said, in the absence of any contra-indication he generally administered gas and ether, using a Clover's inhaler with a tap in the single-mouth apparatus attached to the respirator bag. To that tap a tube may be applied through which N₂O gas may be allowed to pass from a gas cylinder until the bag is distended. This is generally sufficient, and the inhalation of the ether inhaler having been kept at "O" until the patient has had several respirations of gas, it (the indicator) may be moved one-third towards "1" and so on by thirds, allowing several respirations at each stage, until the "1" is passed and the "2" reached. When, or soon after, that is at the expiration of two to four minutes, the patient will be anaesthetised and ready for operation. So far it is often unnecessary and inadvisable to allow respirations of fresh air. Now and henceforward during the operation the complication, respiration, state of the pupil, or moisture of the skin will suggest the necessity or not of raising the face-piece and allowing respirations of fresh air, as well as the number of fresh respirations called for. Generally cases mentioned gas and ether, or ether alone, are the anaesthetics to be preferred. When gas and ether are employed the gas should be used sparingly or the stage of anesthesia will be too long; exceptionally it will be found that excessive nervousness or fear, the excitement of an unusual amount of cough, congestion, cyanosis, or too abundant secretion, is induced by ether, so that it may appear that the continuation of that agent was prove unsatisfactory, and then a change to chloroform will be advisable, and this agent being substituted for the ether it will be found that the previous effect of the ether renders a much smaller amount of chloroform necessary, so that when it has been administered first it is advisable not to be too precipitate in making the change, as often a little patience is all that is necessary under the circumstances. These remarks apply to most cases except some ischio-rectal abscesses and fistulae that are associated with tuberculous disease of the lungs. Whitehead's operation for piles takes so much longer than the operation by ligature, and by reason of the uncertainty, always attendant, hemorrhage, as well as the trussed-up condition of the patient, with its attendant complications, that the question arises, Are the advantages of Whitehead's operation over that of the ligature, if there be any, worth the extra risk that is undoubtedly incurred by the patient at the time of the operation, to say nothing of, in some cases, at least, prolonged convalescence that must be involved by the comparatively very great loss of blood that takes place?

For anal fissure and fistula, gas and ether prove an excellent anaesthetic in most cases, but fistula in ano is so frequently associated with tubercle of the lung that it is not uncommon to have to decide what anaesthetic or anaesthetics will be best for a particular case. When there is little or no irritability of the respiratory tract, gas or ether may answer well. If necessary, a change may be made to chloroform with less hesitation than in patients whose lungs are sound. The sensibility of the skin in the region of the fistula in such cases is often so impaired from inflammation that the patient may suffer least in the long run if the undermined skin is cut away and the sinus is scraped without an anaesthetic, or only a local one, especially when there is great irritability of the lung and tendency to hemoptysis and the general condition bad. In some cases chloroform should be used throughout. In numbers of operations for excision of the rectum lasting from thirty minutes to about two hours, in various positions, the anxieties he called to mind, with one exception, arose on account of hemorrhage from time to time during an operation, circulatory failure, which always improved as soon as the hemorrhage was controlled. The exception was a case in which occasion for artificial respiration arose at the outset of the operation, and on the restoration of the patient, the operation, a long one, was continued and concluded. The subsequent progress of the case showed the patient to be of exceptionally low vitality. Any of the positions of the patient adopted for the operation, favouring as they did the flow of secretions from the mouth, and being antagonistic to the falling back of the tongue, led to an absence of the troubles commonly met with. The hemorrhage in such operations, rendered the amount of anaesthetic necessary less than under ordinary circumstances. He then read notes of half a dozen consecutive cases in which ether was used, the procedure of administering an anesthetic by inhalation in two to four minutes and the fact that there was slight or no sickness at all afterwards. In regard to the administration of somnoform, his experience led him to conclude that it was unsuitable for rectal cases, although if used as a preliminary to the administration of chloroform he was remarkably struck by its effect, as, in the course of half a minute's administration of chloroform following the somnoform, suitable anesthesia was obtained which could be easily and favourably maintained by chloroform. If his further experience confirms this, he considers that somnoform or some such agent as a preliminary to chloroform is a very valuable thing in the art of inducing and maintaining anesthesia. In using local anaesthetics for these operations it is perhaps advisable to limit them to patients of strong will and who are especially desirous of avoiding general anesthesia, and in cases that the surgeon knows at the outset exactly how much he may have to do; and he should bear in mind that the patient, by instinctively shrinking from the operation, and by drawing in the anal region, prevents the surgeon from obtaining full access to the part to be operated upon, and in the end the patient may not be grateful for having suffered a greater amount of mental or physical pain than was anticipated and which may readily be avoided, the operations being more likely to be needed when local anaesthetics have been used than when general anaesthetics have been employed. The surgeon's reason for employing a local anaesthetic may depend upon the general condition of the patient, the nature of, and the time necessary, for the operation. The possible absorption of cocaine should be limited to about a grain. Eucaine may be used more freely, opening an considerable, whether it is preferable to use a local or general anaesthetic will be best determined by considering all the circumstances of any particular case. There are many things to be considered, and when not used in rectal cases not the least of them is, that surgery may not have fair play, and the operator's reputation may come in for more than its share of the consequences.

Vienna Clinical Lectures.

BLUE LIGHT IN LUPUS.

By Dr. Gustav Kaiser.
Professor of Dermatology in the University of Vienna:

[From our own Correspondent.]

It is generally admitted that the blue rays are the most potent factor in the therapeutic treatment where deep structures are to be acted on. How these results are brought about is a question that is at present engaging serious attention, as none can yet say with any degree of safety that the morbid germ is actually killed, nor will the dogmas of a physiological change in the tissue by the rays be accepted as a final settlement of the enigma. If an opinion were to be given I should be inclined to espouse the latter theory of a physiological condition being produced that
leads to a healthy result; at the same time I should not go so far as to deny the possibility of the rays penetrating the morbid germ. I need not enter into an elaborate analysis of the rays peculiar to the treatment of disease, as the chemical rays are now believed to be the principal ones in therapy, and apparently those in the violet band of the spectrum, and a few of the ultra-violet with very narrow undulations. As these rays are largely in electric light it is needless to add that this is the best source for obtaining such chemical rays. I shall first give three examples of my own results as a proof of the efficacy of these rays, and afterwards offer my opinion for finding my belief in the efficacy of the blue rays alone.

Frau Maria E. suffered for two years from lupus vulgaris of the nose and one cheek. After seventeen sittings under the blue rays a distinct reddening set in, followed by a pale, blanched desquamation. After forty sittings there was still a smooth cicatrix with considerable reddening, but by the seventeenth sitting the cicatrix harmonised perfectly with the surrounding tissue. The patient was not treated with a lens, but simply by rays passed through plain blue glass, with results that may be seen in Figs. 1 and 2.

My reason for believing in this special ray as a therapeutic agent is founded on the conviction that it penetrates deeper and imparts its energy at a deeper plane than the other constituents of light. If expressed seriatim, the following advantages might be enumerated:

1. Blue light, when good glass, or a combination of lenses, are used, may have an intensity of 5,000 to 10,000 candle-power without injuring the tissues, as the heat rays are quite absorbed by the glass, leaving the resulting effects quite cool. Hitherto the glass of the different instruments have been fitted with common window glass, which is not effectual in a therapeutic sense. If, however, a good glass be used from a good factory nothing new will be obtained by Sterkel's device.

2. By this treatment, when the light is reflected and then concentrated by means of lenses, no loss of light takes place, and thus a weaker light can be economically used. It may be contended, and has even been affirmed, that this method is only a feeble sun-bath and many hundred times less than Finsen's lamp or the electric light, but it must be remembered that the principle of those lights depend on the ultra-violet rays and not the blue light, as in my own method. Recently Finsen's lamp has been reduced to twenty amperes without the rays being reflected or contracted, which must reduce the intensity of the light.

3. By using the "Magnalium Spiegel" in my own method none of the chemical rays are absorbed, but reflected unaffected on to the patient without any loss of intensity, while the heat rays are separated.

4. It may be contended that the blue rays are not entirely free from the ultra-violet ones, but it is proved by experiment that the blue light contains no ultra-violet rays with a wave vibration of 3,500, as all below that are absorbed by the glass. This can be simply measured on the tissues, which has on occasion been by the author confirmed by others, if a healthy man be placed in a dark room where all rays are carefully excluded except the blue light, which can be done by passing through a dark screen and testing with the spectroscope. If this procedure be followed by
attaching to the back of the patient a bromide or silver film it will be found that the blue rays are in direct proportion to the distance and intensity of the source, although they pass more easily through anaemic bones than those loaded with blood. The shortest time on record by which the film is affected after washing away the movements of breathing is twenty-five minutes to produce a good diagnostic film.

5. These rays are gradually absorbed by the different structures through which they pass, but without that burning effect on the cutis common to the red rays, which do not penetrate vascular tissue so easily as the blue light; therefore, if blue rays pass out of the body on to a negative plate there must be a loss, but certainly not so great as in another former light. My own opponents have been good enough to make a presumptive calculation which I do not find fault with. If 25 per cent. is lost in the first layer of tissue, and therefore absorbed, 75 per cent. is left. They go further, and give a fourth of this to the next layer, or 18 per cent., leaving 57 per cent. again one-fourth of this, or 29 per cent. passing out of the body, or 96:4 per cent. retained in the body. This is surely no great loss, as many drugs have a far greater reduction in the alimentary canal. Another proof of their efficacy is found in the fact of relieving pain and even producing anesthesia, notwithstanding the supposed loss in their application.

6. A reflected arc light is only sunlight greatly intensified, and when applied directly may produce severe scorching. It is difficult, therefore, to reason that the rays have lost their efficacy by removing the red and yellow rays. The therapeutic value of Finsen's rays must be attributed to the blue rays and the ultraviolet fraction of a lamp of sixty-five to eighty amperes, which is made quite cool in a concentrator fitted with a current of cold distilled water. It must be conceded that the real virtue of Finsen's treatment lies in the use of the chemical rays of light.

More concisely stated, we may conclude that blue rays stimulate the metamorphosis of the body, that ultraviolet rays are more efficacious; that the chemical rays are the principal therapeutic agent; that blue light has results in direct proportion to the distance and intensity of the source; that these penetrate vascular tissue so easily as to operate effectively on the deeper structures, which is proved by the calming and anæsthetising results obtained from their use.

BRITISH SANATORIA FOR CONSUMPTION.—III.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

WOODBURN SANATORIUM, MORNINGSIDES, EDINBURGH.

It seems to be the fashion now to establish sanatoria in districts far removed from the dwellings of the ordinary phthisical sufferers, often, it is true, peculiarly fitted by Nature for the advantageous treatment of the consumptive, but remote and not readily accessible, and frequently necessitating much discomfort for the patient and inconvenience to the friends.

There is certainly a great need for suitable sanatoria in close touch with our large centres of population, to which cases can be speedily and easily removed and carefully watched and adequately treated before attempting the sometimes somewhat risky experiment of sending them a long journey to a far-distant sanatorium.

Woodburn Sanatorium, Morningside, Edinburgh, admirably illustrates how satisfactorily such an institution for the tuberculous may be conducted with town and, indeed, in a climate not characterised by perpetual summer.

Woodburn is an excellent type of the comparatively small private sanatorium. It is situated in the suburbs of Edinburgh and on the confines of the country. The main building of the sanatorium consists of a well-adapted old mansion house. The grounds, some six acres in extent, are well wooded, protected on all sides, abundantly provided with paths of various gradients, and peculiarly suited for the carrying out of a carefully graduated pedestrianism. The south outlook from the sanatorium is charming, with the Blackford, Braid, and Pentland Hills forming a background which not only protects the body but powerfully attracts the mind.

The accommodation in the main building, although limited, is excellently planned. The bedrooms are well situated, opening on large corridors, and thoroughly ventilated. The drawing-room is a large and handsome room 40 ft. long by 30 ft. broad and 22 ft. high, and opening on three sides. The large dining-room is also well placed.

The special feature of the sanatorium, however, is the admirable plan of the two rooms on the first floor, each being 15 ft. long by 11 ft. broad and 11½ ft. high. Each room is ventilated by a large open window on the south side, a large louvre over the door opening into a corridor which runs the whole length of the pavilion, and open fireplaces. The structure is raised on piles, the whole being four feet above the ground. It is built of wood, covered with oak shingles, and is lined with felt and faced with matchboarding. The floors are waxed and polished and the walls varnished.

Woodburn Sanatorium can accommodate twenty patients. Treatment is carried on in accordance with the best principles of hygienic management. Dr. Isabella Mears, who is assisted by another resident physician, devotes her whole time to the personal care of the patients. Dr. Mears has recently issued an interesting brochure on "Open-Air Treatment."

Considerable attention is devoted to the dietetic direction of the cases, and an abundant meat diet is provided. Dr. J. J. Calbraith, the recent resident physician, has presented his conclusions on this matter in a recent article on "The Dietetic Treatment of Pulmonary Tuberculosis from the Point of View of its Haematology", and shows that cases treated by the open-air method and on a diet rich in animal nitrogen present a moderate constant leucocytosis, a large absorption leucocytosis, and an almost constant eosinophilia.

Woodburn is well placed in sandy soil overlying sandstone rock. It is also provided with both natural and artificial shelters, and there are sleeping huts for specially selected cases. Dr. R. W. Philip attends as the consulting physician. The inclusive charge is five guineas weekly. The sanatorium can be quickly reached from Edinburgh by ordinary cab, and there is telephonic connection (34, Morningside, Edinburgh).

THE GRAMPIAN SANATORIUM.

Upper Speyside has for long proved a highly favoured and favourite resort of invalids and those in search of mental invigoration and physical recreation; and a now extensive experience has abundantly proved its suitability for the hygienic treatment of many cases of pulmonary tuberculosis. In the spring of 1890, when no private sanatorium for the open-air treatment existed in Scotland, Dr. de Watteville, in a private house slightly modified for the purpose, began the hygienic treatment of these cases in accordance with the principles which had already achieved led to the building of the Grampian Sanatorium, which was completed in 1901.

It is situated near Kingussie, in the Badenoch or Upper Speyside district of Perthshire, It stands in the valley on the right bank of the Gynack, a small tributary of the Spey, at an elevation of 860 feet above sea-level. It is surrounded by woods of Scotch pine, larch and birch. Immediately behind it and protecting
it from the north winds, are the Monaliddah Hills, while on the south-east, at a distance of seven miles, rise the main Grampian range.

The soil is well adapted for the purposes of a sanatorium; it is of glacial drift or till superficially, with mica schist beneath, and being porous, is free from dampness. Numerous foot-paths at varying gradients exist in the grounds, which extend to ten acres, but numerous walks in the immediate neighbourhood are available for cases fitted for more energetic exercise.

The building has been specially constructed with a view to the efficient conduct of treatment in accordance with modern principles. There are two storeys, and twenty patients can be accommodated in the rooms on the south side. Most of the rooms are 13 ft. by 11 ft. and 11 ft. high. The corridors are 80 ft. by 7 ft. All lavatories and other sanitary arrangements are on the side of the corridor furthest removed from the patients’ quarters.

There are several open-air shelters, revolving and stationary, within easy reach of the main building. The sanatorium is lighted by electricity, obtained by a water-power installation from the neighbouring burn. The rooms are heated when necessary by open coal fires.

Treatment is carried on in accordance with the customary methods of procedure. Dr. Walter de Watteville, although he does not reside at the sanatorium, acts as Medical Director, and Mrs. de Watteville occupies the position of matron, but a junior physician resides at the sanatorium.

The Grampian Sanatorium is only three-quarters of a mile from Kingsussie railway station, which is on the main Highland line, four hours’ journey from Edinburgh, five from Glasgow, and thirteen from London. The mail trains which have through carriages from London, Edinburgh, and Glasgow all stop at Kingsussie.

The terms are four guineas per week.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, July 12th, 1903.

ACUTE PULMONARY EDEMA.

At the meeting of the Medical Society, M. Mercklen said that pulmonary edema was common enough in the course of grave pneumonia. Sometimes it constituted a fatal symptom, but in persons affected with pronounced heart disease or in subjects with latent cardiac trouble (the aged, persons suffering from obesity, or habitual drunkards) it could supervene as an early complication of pneumonia. It was thus in a very fat woman, 57, in whom he had observed general edema and hemoglobinuria, which was the first symptoms of pneumonia of the right apex. The patient having succumbed six days afterwards, the autopsy revealed considerable edema of the lungs and a heart loaded with fat. That case, with many others, tended to show that pneumonia in cardiac patients could develop in the same way as the edematosous pneumonia of diphtheria, or the serous pneumonia of Leube. The signs of congestion and edema are noticed before those of hepatisation, which sometimes even passes unperceived. In treating such cases, cardiac tonics were necessary as an adjunct to the anti-infective treatment.

MATERNAL IMPRESSION.

A curious case of maternal impression is reported in the newspaper. A young woman kept company for several months with a man whose body was covered with tattoo marks of every description. Tired of being ill-treated by him, she decided on leaving him, and shortly afterwards married. During her pregnancy she often spoke to her husband of her paramour, whose vengeance she dreaded for having left him. She expressed also her fears that the child would be marked like him. She was delivered recently, and the child was tattooed in several places with the same designs as those of her first lover.

TREATMENT OF RINGWORM OF THE SCALP.

Professor Hallopeau recommends the following treatment for this troublesome affection:—

Wash the head every morning with soap and water; remove with a pin-cers the broken hairs, apply once a week a layer of tincture of cantharides, and rub the whole head morning and evening where the patches are numerous with—

Glycine, 5 j.
Ext. of turpentine, 5 j.
Camphor, 5 j.
Proof spirit 5 x.

But the blistering liquid cannot be employed in conjunction with this.

Apply every morning the following ointment:—

Iodine, x grs.
Vaseline, 3 iss.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, July 11th, 1903.

At the Society of Charity Physicians, Dr. Hübner discussed the SERUM TREATMENT OF SCARLATINA.

In introducing the subject he disclaimed the pronouncement of any judgment, but professed only to report the observations made in his clinic. The chief thing, in his opinion, was the preparation of a real streptococcic serum, as streptococci were very often the cause of the fatal termination.

He had made use of several preparations of serum. First, four cases were treated with Aronson’s serum. In Case 1 the temperature fell the first day, rose again the second, then slowly declined. Upon the whole, very little different from cases treated without injection.

Case 2.—Very severe scarlatina with diphtheroid symptoms; jactitations; 80 grs. were injected; no result. Death on the sixth day.

Case 3.—Temperature variable, the rise due to endocarditis. He drew attention to the endocarditis that rather frequently followed injections.

Case 4.—Very severe and fatal.

Four cases were treated with Moser’s serum.

Case 1.—One hundred and fifty grs. of the Vienna serum were injected. Reduction of temperature could not be denied, but no improvement of the general condition was observed. Death.

Case 2.—No influence, death under symptoms of sepsis; there was also latent tuberculosis of the mesenteric glands.

Case 3.—Decline of the fever, but no special influence of the course of the disease.

Case 4.—Case with destruction of palate; course favourable, but no specialities.

Menzel’s serum, six cases. The speaker considered this to be the best of the preparations.

Case 1.—Rather rapid fall of temperature.

Case 2.—The same, although there were some slight rises.

Case 3.—Effect on the general condition very striking, after semi-consciousness and collapse. Distinct improvement.

Case 4.—Unfavourable case. Taken in on the eighth day of the disease. There was much enlargement of glands and suppurations. After the injections the child seemed quite well, but died suddenly. The autopsy showed marked sepsis of the blood. He
believed the sepsis was present before the injections were given, and that the rise of temperature might be concealed by the reducing action of the serum.

Cases: 1 and 6.—Smooth recovery.

He then reported a case of very severe scarlatina with nerve symptoms, where 70 grs. were injected. The temperature fell on the third day, but the delirium continued in spite of the lower temperature. Some improvement only took place after large doses of chloral hydrate. Then two further cases of recovery, and another very severe septic case with death on the eighth day. Convalescence serum had been injected in the first Med. Klinik, but no results were observed.

Hr. Menzer had had no experience of his own serum in scarlatina; he was of opinion, however, that the sudden death was a result of the injection, as the injection of serum in cases of purulent collections could set up a pus intoxication. He therefore advised the earliest possible injection; later on, the pus was a danger in itself. Serum complications could not be avoided, for as the streptococci were driven everywhere, so the serum itself could be brought into the joints.

Hr. Davidsohn spoke on the post-mortem appearances in the fatal case. The kidneys were like tensely filled sacs. The sudden death probably was due to idiocy sepsis.

Hr. Heubner denied general suppuration in his case. It was of interest to himself that Menzer did not use his serum when suppuration was present. Its employment would then be reduced to a very few cases, and as complications could not be avoided, there was little inducement to use the serum.

Hr. Menzer held that the complication would be slighter. Whoever injected with the object of avoiding complications would be undeceived.

Hr. Lesser made some observations on the Finsen light treatment of lupus.

He said that operative treatment had given some good results, but the cosmetic result had been bad generally—patients were disfigured for life. The light treatment had given excellent results, and was any disadvantage worth mentioning. Some of his cases had now been well for five and six years. Moreover, slight relapses could easily be overcome. The explanation of the action of the light was that the rays excited inflammation; this action was due to the ultraviolet rays and that they had a bactericide action.

The latter had been demonstrated by Nagelschmidt's experiments on guine-pigs. Of nine animals with scarified wounds on which tubercle bacilli were rubbed in, all died of tuberculosis, whilst of nine others treated in the same way, but subsequently being submitted to the light treatment, only one died. One difficulty in the way of the treatment was presented by the cicatrices due to earlier attempts at treatment; another was participation on the side of the mucous membranes. Then there was the obstacle of maintenance during the prolonged treatment and want of means. Gangrene as a result of the treatment was very rare; a tumour-like epithelial growth was seen twice on the parts affected.

Hr. Senator called to mind a case of lupus cured by tuberculin injection that had remained well for thirteen years.

Hr. Schaper had seen a similar case.

Hr. Lesser remarked on the numerous exacerbations that were observed under the tuberculin treatment.

Mr. Edmund Owen, F.R.C.S., Chief Surgeon to the French Hospital in Shaftesbury Avenue, was made Chevalier de la Légion d'Honneur on the occasion of the recent visit of the President to that Institution.

Austria.

At the Gesellschaft Knöpfelmacher showed an eight months child which he considered suffered from the morbid condition described by Barlow. Three weeks ago the child seemed to suffer from severe pains in the legs when touched or moved, which was speedily followed by large swellings, particularly large over the upper part of the femur and lower ends of the tibia. These swellings appeared to affect the muscles and diaphysis of the bones. On the inner surface of the tibia there was distinct fluctuation, which was aspirated, but only blood was drawn from it. The needle, when inserted, came suddenly against the hard, bare bone. Besides these swellings there were a great number of bleeding points about the gums and mucous membrane. The child had been nourished with Bießlert's artificial milk, but for the last seven days it has been fed with raw fresh milk with decided improvement.

Extraction of Foreign Bodies from the Brain.

Holzkneth reported a method which he had recently adopted for extracting foreign bodies from the brain substance by means of a fine pair of forceps and the assistance of the Röntgen rays. His procedure is to get a clear shadow of the object with one lamp, then a second lamp is applied in such a manner as not to admit of a moving of the first till the forceps are inserted and the object extracted. By this method he has been able to remove minute shot of one millimetre from the hypophysis of the brain.

Morbis Basedowii.

Hofbauer showed the meeting a number of graphic results taken from the respiration of patients suffering from morbus Basedowii. He considers these tracings are characteristic of the disease which makes a flatter curve in the respirations and wider intervals between the inspirations and expirations, irregular in form and height. He considers these as very different from the tracings obtained after compression of the trachea in the case of simple struma, cardiac failure, or bronchitis with emphysema. He considers the disturbing cause to be due to other form of irritation than compression.

He referred to Fengel's experiments on animals which had been fed with glandular substance where similar tracings were obtained in the respiration. He also thought our clinical teaching pointed in this direction, and that the cause might be attributed to hypersecretion of the thyroid gland, which thus acted adversely on the respiration, and in many cases resulted in death. Pauli thought that in slight irrtations of Basedowii this curve might be obtained, but he could hardly admit that it is a constant factor. Grossmann held that it was not proved that the struma of Basedowii irritated the superior laryngeal nerve, therefore the increase of pressure and congestion of the lung in the shorter circuit could not be set down as the cause.

Braun objected to the testimony of Hofbauer that the pulse curve during the interval of respiration was not disturbed, while in dyspnoea it was altered.

Königstein quoted from the publication of Hans Königstein, that the action of the bronchial muscles was a notable factor in the distribution of air in the lung. In Basedowii the non-striated muscles are affected, which would, according to his reasoning, explain the present anomalous respiration. Hofbauer
in reply, said that the respiration curve would remain the same for ten minutes, and therefore any disturbance after that could hardly be calculated. He thought Grossmann's theory incorrect, as the respiration curve in cardiac affections is very different.

That the curve, in spite of suspended respiration, produces no change has been amply proved by Pierre Marie. In conclusion, Königstein's theory that the bronchial muscles are the chief factors in the altered curve has not yet been confirmed. Grossmann still contended that the irritatory of the respiratory centre through the vagus must be regarded as the cause of the flattened curve.

DEATH OF PROF. GÜSSENBAUER.

Again the University of Vienna has lost its Rector Magnificus by the death of Professor Güssenbauer, who may be better known as Bilroth's successor in surgery in Vienna. Born in 1842, in Ober Vell Kärten, the son of a surgeon, he came to Vienna, and there studied under Billroth, where he qualified as doctor of medicine in 1866. From this time he was the close confidant of Bilroth, whose assistant he became and continued until 1875, when appointed Professor in Surgery in Liege. On the death of Billroth he returned to Vienna, where he was appointed to the first Chair in Surgery, and latterly Rector of the University. His works are numerous, including "Epithelial Cancer of the Glands, "Pyæmia and Pyosepsia,", &c., &c.

The Operating Theatres.

TOTTENHAM HOSPITAL.

Abdominal Myomectomy.—Dr. Arthur Giles operated on a single woman, aged 34, who had been admitted with the following history:—For twelve months before admission she had suffered great pain in the lower part of the abdomen, which was felt more acutely after standing or walking and also during menstruation. It had become worse for five months and interfered seriously with her work of sick nursing. She complained of a feeling of pressure on the bladder with frequency of micturition. Menstruation was more profuse than formerly. On examination a hard, rounded swelling the size of a billiard ball was felt low down to the right of the uterus and rather behind it, this was believed to be a small ovarian tumour, as the ovary could not be felt independently of it. The left appendages were normal. In view of the disability caused by the tumour, operation was advised and readily agreed to. When the abdomen was opened the tumour was found to be a fibro-myoma which formed an elongated swelling three inches in length by one and a half transversely, springing from the right uterine cornu just behind the Fallopian tube, the attachment being by a loose pedicle at one pole of the tumour. The capsule was cut round close to the uterus and the tumour shelled out, and the wound in the uterus closed by a couple of mattress sutures and a continuous suture of fine silk uniting the peritoneal edges. The appendages on both sides were found to be normal and were left behind. Dr. Giles said that the case presented some interest from the point of view of diagnosis, for it was impossible to distinguish with any certainty between an outlying myoma with a distinct pedicle and a hard ovarian tumour; myoma of this kind, unlike the interstitial and submucous forms, caused no alteration in menstruation; it was true that in this case menstruation had been more profuse, but that was clearly the product of the tumour. The physical examination also was inconclusive, because, as felt bimanually, a subperitoneal myoma situated laterally would convey the same impression as a solid ovarian. The only clue that could be obtained would be the discovery of the ovary apart from the tumour. In this case where the ovary lay behind the tumour such a distinction was not possible. The precise diagnosis was not, however, essential to treatment, because, although in the abstract a subperitoneal myoma did not so urgently call for intervention as an ovarian tumour, the patient in this case required relief, whatever the nature of the tumour might be. Subperitoneal myomectomy, he remarked, was one of the most satisfactory of abdominal operations, because the patient was left with all her organs intact, and the mortality of the operation was so slight as to be almost negligible, quantity, at any rate when dealing with isolated tumours. When subperitoneal myomata were multiple the indication for myomectomy was not so clear, because hysterectomy was sometimes a preferable operation. The ovoid shape of the tumour in this case, he pointed out, was unusual, because myomata tended to a spherical shape, especially when pedunculated. The ovoid shape was accounted for on finding, by cutting the tumour across, that several spherical tumours were contained within one capsule.

The patient made a satisfactory recovery and left the hospital on the nineteenth day after operation.

CANCER HOSPITAL.

Operation for Appendicitis.—Mr. Bowreman Jessett operated on an unmarried woman, aged 44, who had suffered from occasional vomiting for some months with intermittent pain in the right iliac fossa. The bowels were sometimes constipated and sometimes diarrhoea; flatulence also was present, and on one or two occasions pus was discharged from the vagina. On examination he had found a great deal of tenderness in the right iliac fossa, especially on deep pressure; there was distinct fulness over the region of the appendix. Rectiulm.—On bimanual examination, fulness and tenderness were found on pressing the finger in the fornix. Operation was recommended. On opening the abdomen in the usual position the appendix was discovered to be bound down and adherent to the right Fallopian tube. With some difficulty the appendix was separated from the tube and removed by a simple ligature being passed round its base and tied firmly. The mucous membrane was cut out and a drop of pure carbolic acid applied, the divided end being then carefully stitched over and covered with peritoneum. The Fallopian tube was then examined, and it was deemed desirable to remove it. Mr. Jessett said that the case was of considerable interest from the fact of the appendix being adherent to the Fallopian tube, and the discharge of pus escaping through the vagina, presumably through the uterus, as no other opening into the vagina could be discovered. He preferred ligatur- ing the appendix with a fine silk ligature, as he had found by experience that if these were tied firmly the mucous coat of the appendix was absolutely divided through and the piece between the ligature and the divided end was readily removed, after which the divided end was sutured over with catgut and covered with peritoneum.

The patient made excellent recovery.

The Southport meeting of the British Association opens on Wednesday, September 9th, and promises to be one of particular interest.

This summer the number of matriculated students in the German Universities amounts to 37,813, and of these 6,204 are returned as belonging to the Faculty of Medicine.
THE HYGIENE OF THE PEOPLE.

The Presidential Address, delivered by the Earl of Stamford at the recent Congress of the Sanitary Institute, deals with certain aspects of public health well deserving of attention by those interested in the progress of hygiene. In discussing the question of over-crowding and slum dwellings the blame is usually thrown upon unscrupulous landlords, no doubt with ample justification. Nevertheless, it must be admitted that much of the ill-health experienced by slum-dwellers is directly due to their ignorance of, and indifference to, matters concerning personal and general hygiene. It is a common complaint that certain classes of the population will make pig-styes of model dwellings in a very short space of time, and we are invited to base our hopes of reform upon the education of these classes in the principles and practice of cleanliness. The causes of this neglect, however, lie much lower down. Personal cleanliness may be taken as a measure of self-respect, and self-respect, as we understand it, is well-nigh impossible under conditions of life which tend to reduce the human being to the level of the brute. Nevertheless, much may be done under the present system of elementary education to inculcate the principles of hygiene, but to be efficacious the instruction must be made part and parcel of the scheme of national education, and, to begin with, the teachers themselves must be invited to become proficient therein. The community at large is deeply interested in the dissemination of sanitary principles among the very poor, for, as Dr. Ferrier once remarked, the safety of the rich is intimately connected with the welfare of the poor. So long as we allow our slums to remain the breeding-spots of disease, so long will all classes of society suffer the penalty thereof. In spite of the numerous legislative attempts to grapple with the sanitation of workshops and factories, much still remains to be achieved. One of the great obstacles is the apathy of the local authorities, and their indisposition to recognise their responsibility. Nor can this excite surprise, seeing that these local authorities are in such large measure composed of men who are directly interested, or believe themselves to be interested, in perpetuating existing conditions. We are assured that, owing to careless draughtsmanship and want of careful definition, the majority of workshops are in very much the same condition as that of the cotton factories in the early part of the nineteenth century, when the law, from its indefinite nature and the absence of specific requirements, remained a dead letter. The campaign which has been inaugurated against consumption will, if actively prosecuted, aid powerfully in disseminating a knowledge of hygiene among those most affected by insanitary methods of life. Just as antiseptic principles taught us the primary value of cleanliness, so the war against tuberculosis will serve to educate the people in a knowledge of the importance of fresh air, which, after all, is only another form of personal cleanliness. The all important principle enunciated by the orator is that sanitary administration necessarily depends for its success on the voluntary co-operation of all and sundry. No administration, however ornate and well organised, can oblige people to "live clean and avoid sack." That can only be attained by convincing the individual of his personal interest in the matter.

THE PATHOLOGY OF HAY FEVER.

It is a notorious fact that many of the minor ills of life have not, as yet, been found to possess a sound or constant pathological basis. Some of them are inflammatory, such as the common cold, while others, like the so-called "hay-fever," appear to be of a more complex nature. This troublesome affection, which is at present exciting a good deal of comment in the public Press, has many points in common with functional nerve disease, so that it is considered by not a few accurate clinical observers as a vaso-motor nasal neurosis. The periodicity of the attacks, the well-marked neurotic character of the majority of the sufferers therefrom, its analogy with other neuroses, such as paroxysmal sneezing, and the fact that it is apt to be excited in predisposed individuals by olfactory and optical stimuli, apart from the proximity to hay-fields, tend strongly to support this view. The psychical factor cannot, therefore, be totally ignored. Exposure to strong sunlight and the emanations from certain animals are well-known exciting causes of a symptom-complex indistinguishable from hay-fever. B. Fränkel has described similar attacks, induced by railway travelling, under the name "eisenbahn Schnupfen." The contact of the nasal mucous membrane has, naturally, received a good deal of attention, and various absor-
maliities have been discovered, such as hyper-
trophic rhinitis, persistent nasal spurs, and polypi, 
which have been thought to be connected with 
the disease. On the other hand, these local 
affections are common enough in those who have 
ever suffered from hay-fever, or any acute 
paroxysmal nasal catarrh, and the mucous mem-
brane is frequently seen to be perfectly normal in 
many cases of this peculiar disease. The recent 
work of Professor Dunbar, of Hamburg, in ex-
tracting from the pollen of certain grasses (notably 
the Anthoxanthum odoratum, the Agropyrum 
repens, maize, wheat and rye) a toxin which, when 
instilled into the eyes or nostrils of individuals 
predisposed to hay-fever, gives rise to the charac-
teristic symptoms of the disease, is a distinct 
advance in the elucidation of this mysterious 
malady. Dr. Dunbar was able to reproduce the 
disorder in winter by hypodermic injection of the 
toxin, which appears to be of the nature of an 
alkaloid. After careful experiment, it was found 
that an antitoxin could be produced which, when 
mixed with equal parts of the toxin of a known 
dilution, neutralised its specific effects. Thus the 
way was prepared for the therapeutic application 
of the new serum, and in several instances relief 
or disappearance of the symptoms was procured. 
Most of the experiments have been confirmed by 
Sir Felix Semon, and Dr. M'Bridge in this country, 
and although the whole matter was still to be con-
sidered sub judice, yet the possibilities of being 
able to do more than has hitherto been accom-
plished for the treatment of this troublesome 
affection seem more than likely. A special 
vaso-motor susceptibility may be all that is 
required for the toxin to produce its effect, though 
at the same time, the patients upon whom the 
experiments were made do not appear to have 
been in the least neurotic. We are, then, driven 
back to the local theory which, in the light of 
recent research affords the best explanation of 
the pathology of hay-fever.

THE PHYSIOLOGY OF THE MODERN 
CORSET.

The ways of women, so far as dress and fashion 
are concerned, are calculated to bring despair of 
the deepest and most melancholy type to the 
scientific investigator of medical problems. To 
put the matter briefly, their methods are so constit-
tuted as to set at defiance the plain and obvious 
teachings alike of the physiologist, the anatomist 
and the physician. Their ideal is to reduce the 
universal female form to one abnormal shape, and 
to retain the lines of that position by a rigid appar-
atus that would be condemned at sight by any 
jury of orthopaedic surgeons. It seems unlikely, 
however, that women will relinquish the corset on 
merely rational grounds. The only chance is that 
some leader of society will set the fashion of 
abstention from that much-prized article of attire, 
and thereby invoke the aid of a more powerful 
deity than that of reason. The bodily evils 
consequent upon the prolonged use of corsets— 
apart from the question of "tight lacing"—have 
long been recognised by the medical profession.

Notwithstanding that fact, however, it seems likely 
judging from recently published articles, that this 
fertile field of inquiry is by no means exhausted 
from the scientific point of view. Two interesting 
original communications, for example, bearing 
upon this subject have recently appeared in the 
columns of THE MEDICAL PRESS AND CIRCULAR, 
one by Dr. William Williams and the other by 
Dr. W. E. Fothergill. The first-mentioned author 
attributed the frequency of chlorosis in young 
females to the effect of their peculiar dress, whereby 
girls suffered more or less serious damage until 
their shapes were permanently altered and the 
abdominal organs became acclimatised to the 
change of locality. The facts that the general 
condition of the patient as regards flesh is not 
materially affected and that recovery is rapid 
under suitable treatment, he explains by the 
suggestion that the altered state of the blood 
cannot have been of very long duration. With 
these general conclusions Dr. Fothergill agrees, 
and adds thereto several valuable observations of 
his own. Some years ago he published his opinion 
that some forms of anaemia are closely related to 
hepatic toxæmia. "They resist," he continues, 
"all treatment until the liver is relieved from 
pressure by loosening the corset." A systematic 
examination of female hospital patients suffering 
from anaemia has revealed the astonishing fact 
that the waists of young women of the working 
classes measure on an average three inches more 
without the corset than with it. That variation, 
however, disappears after a few weeks' rest in bed, 
and we are thus led to the remarkable conclusion 
that the benefit of rest in bed in the case of female 
patients is due to the fact that relief from the 
pressure of corsets is therein connoted. Dr. 
Fothergill points out that the labouring man throws 
off coat, waistcoat, and braces when at work and 
supports his trousers with a strap which is fastened 
not around his soft abdomen, but over his hard 
pelvis, where it can interfere neither with muscle 
nor with internal organs. The Eastern dancer 
wears divided skirts suspended by a strap similarly 
placed. This method contrasts sharply with the 
course adopted by civilised woman, who wears 
heavy skirts supported by bands round her waist, 
that soft portion of the body which is protected by 
no bony walls. The real object of the corset is to 
protect the waist against the pressure arising from 
the weight of the skirts. The abuse of the corset 
consists in employing it as a means of compres-
sing what it was meant to protect from pressure. 
These and kindred points are well worthy of the 
attention of medical men. Indeed, the question of 
rational dress has an important bearing upon 
both sexes, and might well form a subject of instruc-
tion both before and after medical qualification. 
In the case of women the articles above quoted 
show clearly enough that the abuse of the corset 
may exercise a profound influence upon the well-
being of the individual.

Royal Society of New South Wales.
Notes on Current Topics.

Health and the Twopenny Tube.

The authorities of the Central London Railway during the past year have sought to enhance the attractiveness of their "Tube" by declaring it to be "the coolest place in London." Without discussing the point we are anxious that this popular line should be rendered less inimical to health, for in spite of improvements and promises, there is much which still remains as a serious menace to the health of travellers. The London County Council, with true wisdom, have subjected the important matter of the atmospheric conditions which prevail in the Tube to experts, and the reports recently published afford much food for thought, and will, we trust, be effectual in securing immediate reform. Dr. Frederick Andrews's conclusions are of particular interest. Micro-organisms exist in the air of the Central London Railway in greater proportion than in the fresh air outside. The number is high in proportion to the concentration of human traffic. No pathogenic organisms, other than those commonly present as saprophytes upon the normal body, were detected in such small volumes of the air as could be submitted to analysis, but we fear the tubercle bacillus and other enemies of man must lurk in these subterranean vehicles. Whatever may be said for the coolness of the Tube just at present, it must not be forgotten that the number of organisms capable of growing at the temperature of the human body is considerably greater in the air of the Central London Railway than in fresh air. It is interesting also to note that the number of micro-organisms is generally proportional to the degree of chemical contamination. It would be folly to minimise the advantages of the new means of transit; it has proved a veritable boon to many workers, and medical men have not been slow to avail themselves of its many advantages, but we are particularly concerned that the success which has crowned the enterprise should not be allowed to serve as an argument for resting satisfied with present conditions. The "Tube" offers much that is of lasting benefit to the life of London's workers, but much-needed reforms are urgently required if hygienic righteousness is to prevail, and no effort must be spared to procure the establishment and maintenance of rational measures for the safe-guarding of the health of "Tuppenny Tubers."

Colonial Universities and Post-Graduate Study.

The Imperial spirit is all-pervading. The recent Colonial Universities Conference at Burlington House has clearly demonstrated the need for a closer alliance of British University life with University interests in the Greater Britain beyond the seas. And this is particularly desirable in regard to matters medical. For the maintenance of a high level of efficiency in the practice of the healing art it is most necessary that the best results of the latest research, the most fruitful studies of the most reliable workers, and the highest skill of the ablest teachers should, at least as far as natural circumstances will allow, be freely open to every serious graduate in our wide Empire. The homeland, with its proud and ancient seats of learning, is too apt to forget that medicine is necessarily a progressive science, and an art which is ultimately best tested by utilitarian standards. Our Colonies have founded excellent Universities and are rearing men of great ability, and training students with much aptitude for research work. For the sake of the Old Country, as well as in the interests of the new bloods, it is well that all unnecessary restrictions and every artificial barrier which tends to obstruct the growth of a wide Imperial spirit in medical education should be ruthlessly swept aside. We hope, as the result of the recent Conference, that greater facilities will be afforded by the homeland Universities to our Colonial medics, and that it will become a firmly established custom for our sons from beyond the seas to return to the Motherland and engage in postgraduate study and medical research work, and we further hope the statutes of our British Universities will be so moulded and, if necessary, modified, as to allow of the bestowal of well-deserved academic distinction on those who prove themselves worthy of the same.

Death by Misadventure.

A recent inquest on the body of a man who died from strychnine poisoning throws a sidelight on a custom of pharmaceutical chemists that should be stopped. We refer to the repetition for years of a prescription containing such a lethal drug as morphia. The man, according to the evidence, asked for three ounces of a solution of morphia mixed with one ounce of water, and it seems he had no difficulty in getting the prescription compounded, although it was a very old one. As the law stands the pharmaceutical chemist was within his rights in preparing the mixture and selling it. But it cannot be seriously contended that a physician intends that a patient shall continue taking morphia year after year. Some stop should be put to this pernicious custom that has in many cases made patients opium-eaters. The simplest plan is for the prescriber to write across his prescription "Not to be repeated," and if this is not found to be sufficient to stay the evil, a short Act should be passed regulating the sale of poisons in physicians' prescriptions, and making it illegal to repeat a prescription containing certain drugs when it was marked "Not to be repeated." Further, a general prohibition should be put on the repetition of any prescription containing an hypnotic three months after date, and against it being compounded for any person other than the individual for whom it was written. A publican cannot supply drink to any person whose name is on the Black List as a confirmed drunkard. Why should a pharmaceutical chemist be permitted to go on year after year supplying a confirmed opium-eater with the crude drug or its alkaloids?
Pharyngeal Tubage in Oral Operations.

The difficulties attendant upon certain operations upon the mouth, nose and jaws are chiefly those concerned with the prevention of the inhalation of blood, and the uniform administration of the anesthetic without interfering with the field of the operation. Special skill on the part of the anæsthetist is required, as he often is compelled to stand some distance away, and he may even sometimes have to ascertain the condition of the patient through the medium of the operator, a most undesirable procedure. Deaths from septic pneumonia form a not inconsiderable proportion of those occurring after operations in this region, owing to the decomposition of blood inhaled into the air-passages, even in small quantity. If the head be allowed to hang well over the end of the table, as in operations for cleft palate, the blood will not trickle down into the larynx, but such a position will often be impossible for the surgeon. Dr. Crile, of Cleveland, Ohio, has sought to overcome both these difficulties by employing two rubber tubes, as long as possible, which are passed through the nares to the level of the epiglottis, after full anesthesia and coagulation of the pharynx. The mouth is opened widely, the tongue drawn out, and the entire pharynx is well packed with pieces of gauze. The anæsthetic can be administered entirely away from the area of operation, and the gauze acts as an efficient absorptive plug for blood and mucus. Like many useful appliances in surgery, this is very simple, and allows of the head being placed in any desired position without risk to the patient.

The Mechanical Treatment of Pertussis.

There are few more piteous sights in medical practice than a young child in the throes of a severe paroxysm of whooping-cough. The infant's utter helplessness, the intense straining, the venous congestion, the threatened asphyxia, and the after-vomiting go to make up a clinical picture which, when once seen, can never be forgotten. Some of the complications of the paroxysm may be very serious, such as rupture of the membrana tympani, or even hemiplegia from cerebral hemorrhage, which has been observed by Dr. Samuel West. A specific for pertussis has yet to be found, though there are many drugs which are of great service in controlling the severity of the cough. Believing that mechanical support might prove helpful in the vomiting, which is so frequently an accompaniment of the paroxysm, Dr. Wendell Kilmer, of New York, has devised an electric belt which envelopes the child's thorax or abdomen, or both, as occasion may require, fastened with shoulder-straps to prevent it from slipping down, somewhat analogous to the old sea-sickness belt. He found that the aggravated vomiting in infants was greatly relieved by wearing this simple appliance, that the paroxysmal stage was often aborted, and that the paroxysms themselves were of a milder nature. Drug treatment is, of course, adopted at the same time. A slight irritation of the skin is occasionally produced, but this is stated to be a very trifling disadvantage compared with the great relief caused by wearing the belt.

Laceration of the Bowel.

The diagnosis of the condition of the bowel or stomach immediately after an abdominal injury is of the utmost importance. If laceration of the bowel has occurred and is not diagnosed until six or eight hours have elapsed, the prospect of recovery would be very slight. The most extensive injuries may occur without leaving any evidence, as in Dr. Claybrook's patient (Virginia Semi-monthly), who was caught between a railway engine and a wagon during automatic coupling, and yet when released he walked fifty yards and was then placed on a stretcher. He neither suffered from shock nor vomiting, but was slightly pale and complained of pain in the belly. There was not the slightest bruise or abrasion of the skin on the abdomen, yet there was a rupture of the small bowel at the duodenaljejunal junction, and two branches of the superior mesenteric artery were found spouting five hours after the accident. How are such lesions to be diagnosed? In almost all such cases the rigidity of the abdominal muscles is present and is by many surgeons considered as pathognomonic of a laceration; but in some instances the symptom is not well marked, or even to be recognised until the patient's chance of recovery has been reduced to the vanishing point. Much importance is also placed on the absence of peristalsis, but the symptom is not always present; very free laceration may be found with normal or almost normal peristaltic movements. So difficult is the diagnosis that some surgeons lay down the rule that all abdominal bruises should be operated on, even for diagnostic purposes. And this view receives much support from a case published in the Railway Surgeon of a boy who lifted a small derrick from a railway wagon. It tipped and fell across his abdomen. This happened at 4 p.m. He did not complain of pain or shock, but the next morning he was found dead in his bed, and the autopsy showed complete rupture of the small bowel at the duodenaljejunal junction with free hemorrhage. A late diagnosis in such cases is valueless. If it cannot be made whilst there is still time to operate with a prospect of success its interest is simply academical. Dr. Claybrook from his experience has found that the most constant symptom of laceration is transmission of the heart and respiratory sounds, so as to be audible over the whole abdomen, "at a times even as low as the hypogastrum." He says he never found this condition present unless there was rupture of some hollow organ.

Homes for the Hopeless Consumptive.

In the enthusiasm for the establishment of sanatoria for the arrest of consumption there is some danger that attention may be diverted from an urgent and hitherto altogether inadequately met need. Fortunately, the long prevalent pessimism in regard to the restoration of the subject of consumption has become a thing of the past, and
there is even some risk that a too insistent optimism may hinder progress by its very helpfulness. For it is necessary that the public must learn that pulmonary tuberculosis is a serious disease and medical practitioners will do well to inculcate the necessity for vigorous attention, systematic care, prolonged watching, thorough discipline, and, it may be, a complete re-arrangement of life’s duties if the consumptive patient is to secure and maintain such a degree of restorat on as shall fit him for a useful place in the world of workers. But even at best many a case must be grouped in the melancholy class of “incurable.” The hopeless and comparatively helpless consumptive we shall have among us for long. A burden to himself, and a danger to the community, his state needs immediate attention on both humanitarian and selfish grounds. There can be no doubt that much of the perpetuation of the disease is directly dependent on the uncontrolled phthisical who, in the most advanced stages of his complaint, may now mingle without restraint with those who should be protected from all risks of tuberculous infection. There is the most urgent need for an extension of suitable institutions where advanced and dying consumptives may have their latter days lightened, and where the journey along the dark valley may be brightened by human sympathy and trustworthy assistance, while at the same time a real prophylactic mission is being effected which shall go far to arrest the deplorable spread of the disease which is, under present circumstances, so pathetic an accompaniment of treatment of a hopeless consumptive in his own house, especially when that home is overcrowded, airless, and so situated as to afford all conditions for perpetuation and propagation of a disease which rational measures should be able to almost eliminate in the next two generations. To all interested in the extinction of this bane of civilized life we commend the good work of establishing homes for dying consumptives.

The Ligature in Surgery.

That it is desirable to do away with the use of the ligature in operative surgery hardly admits of question. The subject was discussed at the recent International Medical Congress at Madrid, and there appeared to be a consensus of opinion that the ligature should, as far as possible, be eliminated. It was suggested that compression by a clamp such as Baker Brown used in his earlier ovariotomies might be substituted for them with advantage. Even prior to the Madrid meeting the idea of compression, plus heat, had been put in practice by our American brethren, and the practical value of the method and its facility of application had been demonstrated by one operator, Dr. Keefe, who successfully used it in forty-five coeliotomies, thirteen abdominal hysterectomies, two salpingo-oophorectomies, twenty-eight appendectomies, two ovarian cysts, one resection of intestine, one nephrectomy, one amputation of the thigh, one amputation of the leg, one varicocele, two cases of hemorrhooids, one incision of Meckel’s diverticulum, one case of tubal pregnancy, and two vaginal hysterectomies. The method is not a new one, it is the same in principle as that which Pare displaced when he copied the practice of ligaturing arteries of the Moslem surgeons. It is on the same lines as the heated clamp of 1862. But to-day the clamp is heated by electricity, the instrument is better adapted to the requirements of the surgeon. A perfect instrument has still, however, to be designed.

Deciduoma Malignum.

The existence of a malignant neoplasm, taking origin in decidual remains, has for some years past been a periodical subject of discussion in the obstetrical world. The microscopical appearances which led certain observers to assert that certain malignant growths involving the uterus were of decidual origin long failed to command general assent; indeed, as recently as 1896,1 a specially-appointed committee of the Obstetrical Society of London, after careful investigation, formally denied that the histological features of the specimens submitted to them justified the assumption of a decidual origin. Nevertheless, this view secured the support of an influential minority, and we note that in the last edition of Dr. Jellett’s “Practice of Gynaecology,” the decidual origin of such growths is laid down as fully-established, an assertion to which we thought it necessary to take exception. A paper recently brought before the Obstetrical Society of London by Dr. John Teacher, of Glasgow, affords very conclusive evidence of the validity of the view formerly expressed by Dr. Jellett. Under the title of chorion epithelioma, Dr. Teacher described and demonstrated certain epitheliomatous and hydatidi-form, mole-like structures met with in teratomata. Obviously the committee could not go beyond the material at their disposal, and the fact that their negation must now undergo revision merely shows that patient research has been the means of throwing more light on this obscure subject. As matters stand, however, the term deciduoma malignum is misleading, and should be discarded, since the evidence points strongly to the tumours being of fetal and not of maternal origin.

The Illegitimate Use of the Title “Doctor.”

To check unqualified medical practice is to secure to the medical profession its legitimate birthright. Anything, therefore, that tends to suppress quackery should be welcomed by medical practitioners as a protection to which they are lawfully entitled. Long experience has shown, however, that the blatant charlatan escapes in the vast majority of instances, while the whole machinery of the law is readily set in action by the General Medical Council in the case of disqualified medical men. Now, the man who has been struck off the Register is precisely on the same footing as regards the unqualified quack if either answers any title implying he is a qualified medical practitioner. Yet the General Medical Council will prosecute the disfrocked offender, but leave the other severely alone. Recently, for example, a disregistered man, convicted formerly of a criminal offence, was prosecuted for putting up his title as “Dr.”
So-and-so, with an announcement that he kept a “dispensary and liver pill depot,” and sold “appendicitis pills.” He was fined £10, and will probably have to seek again the shelter of the workhouse. It is, of course, impossible to defend such conduct. At the same time it is curious to reflect that had he never been legally qualified he might have sold appendicitis and liver pills with impunity, and called himself by any title he liked. A glance at the advertising columns of the daily papers will confirm the truth of this assertion. If the Medical Defence Union and General Medical Council can prosecute successfully disregistered men who assume the title of “doctor” and sell pills, why should they not, with equal justice and fulfilment of their duty to the public and the medical profession, prosecute other unqualified persons who do a precisely similar thing?

The Increasing Consumption of Sedatives.

One of the most striking results of the stress and strain of modern life is seen in the increasing desire on every hand for some soothing agent which shall not only lull the hard-working toiler into a sweet sense of bien être and render the clamourings of dull care less audible for a while, but which shall even procure for him the few hours of well-earned slumber of which he would be deprived without such assistance. Every nation, it is true, has its national drug, whether it be opium, haschisch, or alcohol, which produces some or all these effects, but the fact remains that dwellers in cities consume great quantities of sedative nostrums, upon the sale of which there is little or no restriction. The ready accessibility and portability of powerful specifics, the rage for novelty, and the ill-advised recommendation of perfectly well-meaning friends, all conspire to bring about this very undesirable state of affairs. The plea on the part of many is that they can do better mental work with such aid, or that hypnotics are meant for use. The reality of the former excuse is only apparent, for all work undertaken through the unnatural assistance of stimulants which afterwards have a sedative action slowly tends to degenerate in quality. The latter statement is quite true, and hypnotic drugs should never be taken at haphazard without medical supervision. The danger of so doing is constantly being revealed by the painful disclosures in the coroners’ courts. Artificiality, though brilliant at times, can never be so conducive to the mens sana, in corpore sano as the careful and conscientious observance of the simple laws of health.

The Oral Factor in Diagnosis.

There is a great tendency on the part of the physician or surgeon to neglect the condition of the mouth in the course of medical examination. It need hardly be emphasised that an examination of the tongue alone is not sufficient, as very valuable information is often yielded by the teeth, gums, and buccal mucous membrane. In a recent paper by Dr. Harry Campbell, read before the North Midland Branch of the British Dental Association, the necessity for a more thorough and systematic examination of the oral cavity in general diseases was strongly urged. Many cases of obscure facial and cephalic neuralgia can be cleared up by the discovery and timely removal of curious stumps. Oral sepsis, as a factor in the causation of disease, especially of pernicious anaemia, as has been so ably elucidated by Dr. William Hunter, should be ever watched for, and, if necessary, the advice of a skilled dentist might be called into requisition. The presence of even an imperfect “blue-line” upon the gums will clinch the diagnosis where plumbsim is suspected. The teeth of young children and adults often present very characteristic appearances in congenital syphilis, rickets, or scrofula. Similarly, in older patients, the ground down condition of the teeth, as seen in gout, or the pigmentation on the gums met with in Addison’s disease, is worthy of the attention of the physician.

The Employment of Children in Theatres.

The soul of Sir Henry Irving has been much perturbed by the suggestion that theatres do not offer an altogether desirable occupation for the young developing body and evolving mind of our coming generation. We do not deny that great consideration is often shown by the management of theatres in arranging for the comfort and protection of children taking part in the work of the stage, but we do contend, on hygienic and medical grounds, that for most children of tender years the conditions of life inseparable from theatre existence are peculiarly unsuitable. The strain on mind and stress on body are so great that but few should be exposed to the risks. The long hours of rehearsals, the late performances, the irregular life, neglect of dietetic attentions, night work and lack of sleep, combined with environment and numberless influences which necessarily stimulate emotions and sometimes precipitate physiological conditions which should only be manifest when maturity is being approached, mark the theatre to all experienced, unprejudiced and thoughtful minds as being a peculiarly unsuitable sphere for the regular occupation of children.

Fulminating Cholera.

The outbreak of cholera in the Philippine Islands is of singularly sudden onset, and very lethal in its character. In Manila the death-rate has been very high. Out of thirty cases which have occurred during ten days, twenty-eight died, and the two remaining patients are not expected to recover. Of ten consecutive cases, four were already dead when discovered, two died in the ambulance on the way to the hospital, two died within two hours after admission, and the remaining two died within four hours after entrance. The disease carries off the patient so quickly that there is not time to observe symptoms and no indication for treatment or opportunity to establish medication. Medical officers on the spot are of opinion that the sudden deaths are due to paralysis of the cardiac muscle, probably due to the cholera toxin absorbed being so large in amount. There are none of the usual
symptoms of purging or vomiting, the patient in some instances feels a little sick and falls forward dead. The diagnosis is really made from the post-mortem examination. The lethal character of the present epidemic is probably due to the hardships the inhabitants have suffered during the Hispano-American and the present civil war.

The Local Application of Antitoxic Serum.

Although the introduction of the specific antitoxic serum has succeeded in considerably reducing the mortality of diphtheria, yet there are few who would be so bold as to rely upon its hypodermic injection alone without paying any attention to the condition of the fauces, and seeking to apply local remedies at the same time. The diphtheritic membrane acts as a veritable poison factory, which should serve to remind the physician that the disease is primarily a local one. Various agents have been employed with a view to causing the dispersion of the false membrane, some of them acting apparently as direct solvents, and others simply as antiseptics. Dr. Louis Martin, in a recent communication to the Société de Biologie, has found that touching the membrane with the serum not only relieved the pain, but ultimately caused its more rapid disappearance. He at first used ordinary normal serum and afterward employed antitoxin. The serum can be incorporated with a gum basis in the form of a lozenge which can be sucked by the patient, so that gradual continuous action is exerted. The hypodermic injections are used at the same time. The false membrane can be seen to swell up, become more yellow, and finally to disintegrate, but the most noteworthy effect was the diminution of the faecal pain and distress.

Neuralgia Paresthetica.

A condition in which a numbness of the front, and especially the outer side, of the thigh is felt, together with a certain amount of pain on pressure over the area supplied by the external cutaneous nerve was first described by Bernhardt in 1805. The name of "neuralgia paresthetica" was given to it by Roth a few months later. A case of this nature is reported by Dr. Edwin Bramwell, in the Edinburgh Medical Journal for the current month. The patient was a miner, aged 43, who was admitted into hospital for pain in the front of the right thigh on walking and a feeling of coldness in the same region which he had experienced for eighteen months. There was no history of syphilis or rheumatism. No shortening or wasting of the limb was observed, and the reflexes were normal. There was tenderness on pressure over the point of emergence of the external cutaneous nerve through the fascia. Other modes of treatment having failed, resection of a portion of the nerve was performed, and was followed by immediate relief of the symptoms. No pathological changes were found in the excised portion. The symptoms of this curious condition seem to point to the conclusion that it is a definite clinical entity, while the absence of any microscopic changes would indicate that it may be allied to a neurosis.

The prognosis, apart from operation, is very unsatisfactory for complete recovery.

"Thymus Death."

Many cases of fatal asphyxia in infants possess a very obscure origin. Conditions of laryngospasm, paralysis of the respiratory centre, convulsions, morbus cordis, asthma, and other morbid states have been considered to be the cause in some instances. There can be no doubt, as Dr. Crozier Griffith pointed out at the annual meeting of the Association of American Physicians, that a certain proportion of such deaths is directly attributable to the actual pressure of an enlarged thymus gland upon the trachea or great vessels. Others believe that the so-called "thymus death" is due to syncope, dependent upon the disturbance of certain nervous centres, which are in some way influenced by the glandular hypertrophy. Closely associated with this is the condition known as the "status lymphaticus," in which the lymphatic glands are enlarged throughout the body. In all probability, some toxic substance is formed, which, failing to be properly excreted, acts fatally upon the nervous tissues. Whether the hypothetical toxin arises from atrophy of thymus-tissues proper is unknown, but it is certain that the gland plays an important part in metabolism during the first few months of infancy. It is possible that a deficiency in its internal secretion may be responsible for the fatal result.

The Amalgamation Scheme of the Royal and National Orthopedic Hospitals.

A special meeting of the governors of the Royal Orthopedic Hospital was convened for Wednesday last, July 8th, to discuss the scheme of amalgamation with the National Orthopedic Hospital, but representatives of the press were excluded, so that we are only enabled to give a brief report of the proceedings. Objection was taken by Mr. Reeves to the meeting being held in private, but his protest was overruled by the Chairman, Mr. H. H. Marks. We understand that the scheme was sanctioned in principle, and a proposal by Mr. Reeves that the matter should be referred for further consideration to a joint committee was rejected.

The General Medical Council.

The special session of the Council opens to-day (Wednesday), and will probably extend over the following day or days. It will be devoted to the consideration of the Visitors' and Inspectors reports on the examinations of the Universities of Oxford and London, and of the Joint Board in England, as well as to the reports of the Examinations and Education Committees thereon.

The late Mr. W. Cadge, of Norwich, the East Anglian surgeon whose death we recently announced, has left a legacy of five thousand pounds to the Norfolk and Norwich Hospital. During his lifetime Mr. Cadge presented the Institution with two donations of ten thousand pounds each.
Toxicity of Rat Bites.

Practically all we know of the toxic effects of rat bites is due to the diligence and industry of a Japanese physician, Dr. Miyake, who reports thirty cases. The results are in some cases lethal, one case being followed by tetanus and others by secondary infections, due, probably, to septic conditions during treatment. Dr. Miyake divides the disease into three forms—(1) the febrile; (2) the afebrile; and (3) the abortive. The symptoms of the first form are pain at the seat of the bite, fears, tired feeling, headache, dyspnoea, small pulse, cold extremities, delirium, sensory and motor paralysis, collapse, and death. The afebrile form has a well-marked inoculation period, and in most of the cases a rash appears. Dr. Evans has succeeded in finding twenty-six cases in American literature, and since then Dr. F. Sherwood has reported a case in which a boy, eight years old, was bitten over the inner malleus. The teeth of rodents are so clean that it is difficult to understand how a bite from one of them should be followed by such severe symptoms. In Dr. Sherwood's case the incubation period lasted three weeks, and the pyrexia for nine weeks longer, rising at times to 105° F., accompanied by headache, loss of appetite, and pains in the limbs.

A Good Example.

A recent number of the Official Gazette of Spain published the Royal decree announcing, over the signature of the Director-General of Health, the conferring of a pension on all medical health officers who may be incapacitated from work by any epidemic. And in case of death resulting from disease contracted in discharge of their duty their widows and orphans are to receive a pension. If Spain of her necessities is prepared to deal thus with medical officers engaged in public duties, it is not too much to expect a wealthy country like England to follow such a good example.

PERSONAL.

Dr. H. E. Scowcroft has been appointed a District Surgeon in Pahang, Federated Malay States.

Mr. John Tweedy has been elected President of the Ophthalmological Society of Great Britain.

Dr. W. G. Joynt, of the Medical Department of the Gold Coast Colony, has been transferred from Accra to Kumassi for service.

Mr. Jonathan Hutchinson, F.R.S., is to be entertained at dinner on July 23rd at the Trocadero Restaurant, this date coinciding with his seventy-fifth birthday.

H.R.H. Princess Louise, Duchess of Argyll, after opening the Home and Hospital for Jewish Incurables, South Tottenham, on the afternoon of July 3rd, paid a strictly private visit to the Tottenham Hospital, of which institution her Royal Highness is President.

Dr. Frederick Turner, of Buxton, on Saturday received an intimation that his son, Mr. Reginald Turner, D.S.O., who went through the South African War, and won honours for swimming the Tugela River whilst under heavy fire, has been appointed Magistrate for the whole of the Orange River Colony.

Mr. W. S. Lazarus-Barlow, M.D., F.R.C.P., has been appointed Director of Cancer Research Laboratories of the Middlesex Hospital; Mr. W. S. Handley, M.S., Lond., F.R.C.S., has been awarded the Richard Hollins Cancer Research Scholarship, and Mr. W. F. Victor Bonney, M.D., M.S. (London), F.R.C.S. (England), M.R.C.P. (London), has been appointed Obstetric Registrar and Obstetric Tutor.

Special Correspondence.

We do not hold ourselves responsible for the opinions of our correspondents.

[FROM OUR OWN CORRESPONDENTS.]

SCOTLAND.

Memorial Statue to a Medical Man.—A statue in bronze has just been erected of the late Dr. Gorman at Rutherglen, near Glasgow. It occupies a prominent site at the south-east corner of Queen Street, in front of the new Parish Church. It stands on a grey granite pedestal rising ten feet from the street level. The statue itself is about 5 ft. 6 ins. in height. It was unveiled by Colonel J. R. G. Buchan a few days ago in the presence of a large number of spectators. The Town Council attended in their official capacity, Provost Rodger wearing his robes of office. Colonel Buchanan referred to the philanthropic character of the late doctor, and spoke in very warm terms of his qualifications as a surgeon. The inscription on the granite base is: "Dr. James Gorman. Born 1832. Died 1899. Erected by public subscription."

The Ballachulish Dispute.—Dr. Grant has not appealed to the House of Lords in this unfortunate dispute. Meantime, the pursuers, who are the proprietors of the quarries, have asked in the Court of Session, pending the appeal, for execution of the decree granted by their lordships recently. The Court decided that the pursuers were entitled to have the decree of interdict put into execution, but that it should not be carried into effect until the respondent had had reasonable time to get settled elsewhere. In their lordships' opinion, two months would be ample time, and accordingly they ordained that the execution should proceed at the expiry of that time in the district where Dr. Grant is so popular, as well as his professional brethren generally, will look forward with more than the ordinary degree of interest for the final decision of the House of Lords in this apparently oppressive action.

Proposed Increase of Fees in Glasgow University.—We understand it is proposed to raise the class fees from £3 3s. to £4 4s., the amount charged in the majority of the medical classes in Edinburgh University. Already the matter has been before the University Court, and at a meeting recently it was suggested that the fees for clinical teaching should be raised. The total increase, if the proposal should be adopted, would amount to a sum, for hospital ticket and clinical teaching, of ten guineas. Dr. D. C. McVail, a member of the University Court, has strongly protested against the proposed increase, and in doing so has certainly the sympathy and support of the students and their friends. Already a large number of students avail themselves of the Carnegie Fund, and this contemplated raising of the fees on the part of the University authorities is calculated to increase the number of students who would require to take advantage of the Carnegie Fund. This, we think, for various reasons, is quite undesirable, and would be a matter for regret on the part of many students.

BELFAST.

The New Royal Victoria Hospital.—The new Royal Victoria Hospital is now ready for the formal opening by His Majesty the King on the 27th inst., and Professor Sinclair, F.R.C.S., President of the Ulster Branch of the British Medical Association, took
The opportunity of the meeting of that branch in Belfast on Friday, the 10th inst., to invite the medical men of Ulster to luncheon at the hospital and to have a private view of the building. About 350 were present, including some dozen laymen closely associated with the institution. After a sumptuous luncheon served in the large waiting-room of the external department, which easily accommodated all present, Professor Sinclair said he wished to propose two toasts — the King and the Queen, and this having been enthusiastically honoured, he proposed "Success to the Royal Victoria Hospital." Mrs. Pirrie, to whose efforts the success of the scheme is largely due, replied to the toast and showed how all the energy which she devoted to the work for six years, and the financial help she and her husband had been able to give, were really due to the enthusiasm inspired in them by their dear friend the late Professor Cuming. Mr. Crawford, Chairman of the Hospital Committee, having also replied, the Right Hon. W. H. Pirrie proposed the health of Professor Sinclair. After his brief reply, those present proceeded to inspect the building, as far as it is ready for occupation. The work of furnishing is progressing rapidly, and the wards will be ready for use in a few weeks. A detailed description of the hospital will appear in our columns shortly.

Correspondence.

TUBERCULOSIS.
To the Editor of THE MEDICAL PRESS AND CIRCULAR.
SIR,—The Blue Book just published by the Irish Local Government Board tells that forty-seven per cent. of all the deaths during the year 1901 in Ireland were due to tuberculosis. It is to be hoped that the rules now formulated and the instruction given to the public for the prevention and cure of the disease will bear fruit, and that the percentage of deaths will, in time, show a marked fall. It is a fact that when the death-rate from the disease fails the people may become careless and forget the lessons of the past. I would, therefore, that the preventive principles of sunlight and fresh air were taught to every child, that the subject be made compulsory in all our schools. The grounds of my fear are briefly stated, and are as follows:—When Philip V. of Spain died on July 11th, 1746, he was succeeded by his son, Ferdinand VI., the peacemaker, and the well-beloved, whose life was spent in promoting the peaceful arts and industries, and in acts of benevolence. He established the Academy of Saint Ferdinando for the study of painting, sculpture, architecture and so forth. In 1752 he established the botanical gardens of Madrid, and in connection with them founded university chairs for the study of the natural sciences. And, ably seconded by Don Henon, Somodevilla, Marquis of Ensenada, he did much to advance medicine. To him may be traced the division of the whole country into medical districts, in each of which is a medical officer, an arrangement which was closely followed in the Irish Medical Charities Act. To each of the medical officers Ensenada issued the following instructions, and to each of them he sent word that the people were to be taught the precepts laid down: They are as follows:—"Experience having shown how dangerous is the use of linen, furniture and articles which have been used by persons afflicted with, or who have died of hectic, phthisical, or other contagious diseases, we enjoin on all physicians to give notice of those persons who are sick with, or who have died of phthisis, so that the Alcaide may cause the linen, clothing, furniture and other objects used personally by which have been in his department to be burned. So that the Alcaide may also order the apartment in which the patient died to be plastered and whitewashed, and the flooring or flagging of the room or alcove in which the patient's bed was placed to be changed. Besides, a registration must be kept of places from which clothing found in the shops of second-hand clothes dealers comes, with information as to the names and residences of the vendors, as well as the persons who have used the linen and garments, and dealers in old clothes ordinarily doing business in infected clothes. The Alcaide shall issue a paper attesting that the said goods are free from contagion; this paper shall be the sole authorisation by which dealers in second-hand goods shall be allowed to sell such goods. Any physician who will not give notice of consumptive patients, or those who have died of consumption, to the Alcaide of his quarter, shall incur, for the non-fulfilment of 200 ducats and suspension from the practise of his profession for one year; and for repetition of the offence a fine of 400 ducats and the punishment of exile for four years. All other persons (infirmaries, etc.) who make no mention of such cases who will not report the case shall incur a penalty of thirty days in prison for the first offence, and four years in the galleys for the second offence. Civil, religious, and military authorities shall cause to be burned in civil and military hospitals all linen which shall have been used by phthisical civilians or soldiers."

In time these excellent sanitary laws were neglected, and the unhygienic conditions of life reached the awful state described in 1800 by Dr. E. O. Shakespeare in his "Report on Cholera," which he published as United States Commissioner by Order of President Cleveland.

I am, Sir, yours truly,

GEORGE FOY.

REFORM OF THE MEDICAL AND DENTAL ACTS.
To the Editor of THE MEDICAL PRESS AND CIRCULAR.
SIR,—Your correspondent, "M.R.C.S., L.D.S.," is quite right when he points out that amendment of the Medical and Dental Acts would prove far more beneficial to the public than to the professions; and it is impossible to doubt, as he suggests, that if the voice of the united professions could be made audible, loudly and persistently, the reforms so urgently called for would be conceded by the Legislature. As in the case of quack medicines. Such an enquiry would establish the fact that quackery—including the trade in quack medicines—forms ultimately a source of as much profit as injury to the legitimate practitioner. Quackery forms a potent factor in the deterioration of the public health. Vast numbers of invalids are to be found in every class of society with simple maladies rendered chronic and serious diseases rendered hopeless through delay whilst relying upon quack treatment or fraudulently panaceas. Of these classes of invalids with ailments manufactured or aggravated by quackery, the vast majority gravitate into the hands of qualified men; and thus money which would not otherwise be earned is put into the pockets of untrained men. In dental surgery, of which I am a practitioner, a large number of cases, mostly among weak and foolish women, constantly return to their family dentist after having had their teeth decayed and needings set of artificial substitutes which proper treatment might have rendered unnecessary for years.

I am, Sir, yours truly,
A CONSULTING DENTAL SURGEON.
London, July 11th, 1903.
THE CARLYLE-FRousse CONTROVERSY.

To the Editor of The Medical Press and Circular.

Sir,—The recent taking up of this painful subject by certain writers, and referred to in your admirable editorial note, seems the more gratuitous in view of the fact that both Froude and Carlyle as writers, if not dead, are rapidly dying, and are already less noticed by any class of reader or student as may turn to their pages to gratify a merely literary curiosity. The matrimonial troubles of Carlyle are of not the smallest importance to a generation placed by the advance of science, including historical science, far in advance of the erroneous premises and generalisations advanced in his writings. By his enthusiasm for honesty, his hatred of sham, and his demonstration of the true source of contentment to be gained by hard work and self-sacrifice alone, Carlyle, like Ruskin and Froude, exercised a powerful influence for good upon his generation. But his writings were for a day, not for all time, and, I repeat, he, as an author, virtually disowned. I see no advantage to besmirch the memory of an honest writer by dragging into view the story of his miserable human frailties when the exposure can have no other result than to gratify the prurient curiosity of the frivolous portion of society.

I am, Sir, yours truly,

H. S.

July 10th, 1903.

GORDON BLACKMAILING CASE.

The following letter has been sent to us for publication. We trust that it may obtain a speedy response from the medical profession:

Sir,—Recognising the serious issues to the profession involved in the recent blackmailing proceedings taken against Dr. Alex. Gordon, Dublin, and the courageous way in which he resisted the attack on his character, a subscription list has been opened in connection with the fund started by The Medical Press and Circular to assist in defraying the heavy legal expenses incurred by Dr. Gordon in bringing about a result which will have a far-reaching effect in safeguarding his brother practitioners from attacks of a similar nature in the future. We hope you will see your way to join the movement. Dr. Robert S. Wayland, 54 South Richmond Street, Dublin, has kindly consented to act as Hon. Secretary, and Dr. Andrew J. Horne, 94 Merrion Square, Dublin, as Hon. Treasurer. These gentlemen will thankfully receive and acknowledge subscriptions sent to them for the purpose. Subscriptions will also be received and acknowledged by The Medical Press and Circular.

We are, Sir, yours truly,

A. V. MACAN,
President Royal College of Physicians, Ireland.

L. H. ORMESBY,
President Royal College of Surgeons, Ireland.

Obituary.

LIEUTENANT J. H. FERRIS, M.B., B.Ch.

We regret to announce the untimely death of Lieutenant J. H. Ferris, I.M.S., in his twenty-eighth year, at the Station Hospital, Poona. He was born in the late Rev. Mr. Ferris, at Windsor Presbyterian Church, Belfast, and was educated at Queen's College and the Belfast Medical School, where he was most popular with his teachers and fellow-students. After graduation, he obtained a commission in the Indian Medical Service, and was stationed at Belgaum. He was taken ill early in May, and went for change to Mahabaleshwar, but on arrival there he was found to be suffering from enteric, and had to be sent down to hospital at Poona, where he arrived with a temperature of 105°. For some days he progressed favourably, then sank and died on June 15th. He was buried with military honours in the cemetery at Poona.

DR. O. O. MOCHTOUKOWSKI.

The death of M. Mochtoukowski, the Russian neurologist, is announced. He was born in the Government of Kherson in 1845. His father was a village schoolmaster. Young Mochtoukowski was educated in the Gymnasium of Kief, from which he graduated to the University of Wladimir. In 1869 he joined the medical school, and in 1871 became a resident in the Odessa Hospital, where he remained until 1877. In the latter year he was appointed neurologist to the hospital, which position he occupied until 1893, when he was called to the chair of neurology in the Clinic of the Grand Duchess Helen Pavlovna, St. Petersburg. In 1877 he obtained his M.D., his thesis being "A Contribution to the Pathology and Treatment of Typhus." Whilst in practice in Odessa he established a review, "The Work of the Medical Staff of the Odessa Hospital." In 1898 he published a series of papers on locomotor ataxy in the principal Russian medical journal, "Wachi." We have mentioned but two of his many contributions to medicine; if space permitted we might add a long list of titles of his contributions on bacteriology, histology, serotherapy, and inoculation. He had been a sufferer since the year 1901, when he got a paralytic stroke with aphasia, followed after a time by a series of apoplectic attacks which confined him to bed. Last winter he was removed to Tsarskoje-Selo, and finally to Pavlovsk, where he died on June 18th, 1903.

CLARKE ON ERRORS OF ACCOMMODATION AND REFRACTION. (a)

The preface of this excellent handbook contains the keynote of the whole book: "I have tried to make the following pages . . . essentially practical." Whether the average medical student can afford time to peruse this book or not, he, at all events, may know that by possessing it he has a plain, practical guide to the refraction of the eye, containing enough optics to explain the subject and yet be easily understood by the non-mathematical man. A short chapter on "Optics" is followed by one on the "Optical Properties of the Normal Eye," including an explanation of Snellen's test-types for near and distant vision. Recognising that the majority of students do not intend to become ophthalmic surgeons, Mr. Clarke devotes much attention to asthenopia; not only giving a brief résumé of the varying symptoms, but adding special chapters on muscular and retinal asthenopia, "accommodation," "convergence," "latent deviations of the eye," with
a clear account of the Maddox test, carefully and practically written. While speaking of low degrees of myopia, the author says: "If people learn to recognise indistinct outlines by the aid of other senses in a way that emmetropes can hardly understand, when later in life they can put off the wearing of glasses for any time for many years until extreme old age, what wonder that they and their relatives imagine them to be possessors of remarkably good sight." This fact should be clearly made known to all students, for in general practice they will often hear Mr. Clarke's word used without vision. In the treatment of myopia we are glad to see that Mr. Clarke recommends full correction in all cases whenever practicable, while dissection and removal of the lens is not forgotten; the reader being referred to a text book on ophthalmology for details. One of the most practical chapters in the book is that on "Methods of Examination; Note-taking; Spectacles," while the "Illustrative Cases" will explain to a student in a few words what he would fail to understand if he spent many hours reading chapters upon the theory of such cases. Coloured plates, numerous engravings, "Tests for the Services," an appendix, an index, and a useful card of test types are provided, and the book is a practical monograph, which we can thoroughly recommend to students, specialists and general practitioners.

**Medical News.**

**The Jenner Institute of Preventive Medicine.**

In view of the proposed change of name of this institute, Dr. MacKenzie, as secretary, has sent us the following explanation of the reasons which induced the Council to propose the change of name to the "Lister Institute of Preventive Medicine." As there already exists in London a commercial firm trading under the name of "The Jenner Institute for Calf Lymph," with a prior legal claim to the name of Jenner Institute, the two institutes are constantly supposed to be one and the same, to the inconvenience of both. So great, indeed, has this inconvenience now become and all efforts to meet the difficulty having failed, the sanction of the members and of the Board of Trade to change the name of the institute has been obtained, and the reasons fully explained to the Jenner Memorial Committee, who have acquiesced, though with regret, that a change of name is under circumstances inevitable. The Governing Body propose that in future the institute be known as the "Lister Institute of Preventive Medicine," though it is only fair to Lord Lister to say that this name has been chosen by his colleagues against his own strong personal wish. But they believe their choice, under the circumstances of the case, will be warmly accepted not only by the medical profession, but by all interested in scientific progress, both at home and abroad.

**Society for Relief of Widows and Orphans of Medical Men.**

A quarterly court of the directors of the Society was held on Wednesday last, July 8th, the President, Mr. Christopher Heath, in the Chair. Four new members were elected. There were no fresh applications for grants. The death of one widow was reported, who had received £35 a year since 1885. A sum of £1,328 was voted for distribution among the 54 widows, 13 orphans and the four recipients from the Copeland Fund now receiving half-yearly grants. The expenses were £40 8s. 6d. A legacy of £25 had been received from the executor of Miss Alicia Haw, and a donation of £5 from a relative of a widow, who died in 1883, and had had £50 a year since 1876, as a thankoffering.

**A Victim of Hypnotism.**

"Dr. Bodize, the hypnotic quack, who has for some time past been hypnotising wholesale in Carlfit and the neighbourhood, recently undertook the treatment of a paralysed woman at Longton, and under his influence she expressed herself as feeling much better, and even undertook to address the audience. She could not be brought to a rational head of mind which proved fatal. An inquest was held, and apparently neither the coroner nor the jury saw anything objectionable in an unqualified person inducing a condition of excitement which could not but prove dangerous in such a subject. An inquest under these circumstances is a mere farce, especially as it has long been recognised that the indiscriminate employment of hypnotism is dangerous and otherwise objectionable."

**The North-East London Clinical Society.**

As a commemoration of the closing of its third session, this Society held its first annual dinner at the Great Eastern Hotel, on July 7th. The President, Dr. F. H. Daly, was in the chair. After the loyal toasts had been duly honoured, "The Society" was proposed by the President, who remarked that the large gathering of members and guests (including ladies) was in itself sufficient evidence of the vitality and growth of the Society. He also alluded to the well-sustained discussions which had invariably followed the many excellent papers read at the monthly meetings, and also to the interest in the Society shown by the staff of the Tottenham Hospital. Dr. F. T. Trelisian, of Enfield, responded in a few well-chosen words. The toast of "The Guests" was given by Dr. T. Gilbart-Smith, to which Dr. Percy Kidd, Mr. C. B. Lockwood and Dr. R. Murray Leslie suitably replied. The health of the Chairman was proposed by J. Langton, and a good musical programme contributed greatly towards the success of the evening.

**Royal College of Surgeons in Ireland—Prize List, Summer Session, 1903.**

**Mayne Scholarship:** £15. R. W. Burkitt.
   Carmichael Scholarship: £15. I. Allain.
   Practical Histology: W. St. Leger Moorhead, first prize (£2) and medal; S. H. Massey, second prize (£1) and certificate.
   Practical Chemistry: D. P. Clement, first prize (£2) and medal; H. C. Carden, second prize (£1) and certificate.
   Public Health and Forensic Medicine: Miss C. O'Mara, first prize (£2) and medal; T. W. Browne, second prize (£1) and certificate.
   Materia Medica: R. M. Bronte, first prize (£2) and medal; A. J. Faulkner, second prize (£1) and certificate.
   Obstetrics: F. M. Hewson, first prize (£3) and medal; W. A. Ryan, second prize (£2) and certificate.

The Winter Session will commence on Thursday, October 1st. Preliminary Entrance Examination will be held on Monday, September 21st. Guide for medical students will be forwarded, post free, on written application to the Registrar, Royal College of Surgeons, Stephen's Green, Dublin.

**Tuberculosis Experiments in Germany.**

Professor Kossel, of the Imperial Health Office, read a paper last week before the Berlin Medical Society upon the results of the work done by the Tuberculosis Commission in connection with the investigations made by Professor Koch and Schnetz. Professor Kossel summed up the results of a series of experiments as proving that tuberculosis in the human being can be communicated to cattle, and vice versa. The practical question, namely, which communication was more frequent and how great was the danger attaching to it—remained, however, still undecided. The results of the experiments, which were done under these circumstances by inoculation of calves with human tuberculosis by subcutaneous injection, tend to support Professor Koch's view that the bovine tuberculosis bacillus is of different species from that of human tuberculosis. A definitive opinion on the point is, however, reserved for the result of a series of experiments in which inoculation will be made by means of feeding and inhalation.
Mysterious Death.

An inquest has been held concerning the death of Dr. A. E. Wainwright, who was acting as locum tenens to Dr. Wilson, of Doncaster. Dr. Clarke, who was only twenty-five years of age, and qualified but two years since, was taken suddenly ill on Friday last with pains and shivering and died soon after. The inquiry was adjourned for an analysis to be made of the contents of the stomach. At the adjourned inquest, the analyst to whom the analysis of the contents of the stomach had been entrusted stated that he had not been able to discover traces of any poison. As no further evidence was forthcoming an open verdict was returned.

Death of a Medical Man under Chloroform.

An inquest was held last week by Mr. Troutbeck, on the body of Mr. Sydney Adolphus Bernays, M.R.C.S., L.S.A., aged fifty, of Poplar, who died under an anaesthetic at St. Thomas's Hospital. The autopsy revealed the fact that Mr. Bernays was suffering from chronic tuberculosis, and death was attributed to heart failure.

Labour and Capital. The "Entente Cordiale."

We were privileged to assist at an interesting cere-
mong last week, viz., the presentation of good-conduct medals and bonuses to the deserving employees of Messrs. A. and J. Allen, the well-known manufacturers of toilet ammonia product. The interest of the pro-
cedings lay in the method by which Messrs. Scrub endeavoured to secure the cordial co-operation of their employees by encouraging punctuality, thrift and diligence. The mayor of Lambeth presided, and the proceedings were opened by the Vicar of S. John's, Waterloo Road. Under the system a boy receives annual certificates and a product, after three years enti-
tle him to a bonus of 32.10s., and in four years to 510. The ceremony went off very satisfactorily, and the guests were subsequently entertained at lunch. The problem of reconciling the interests of capital and labour would be greatly simplified if all employers of labour took the same paternal interest in their staff as Messrs. Scrub, and we are pleased to have been permitted to testify to its success.

Memorial to Pasteur.

A memorial to Pasteur was unveiled yesterday at the village of Marnes la Coquette, near Villeneuve l'Etang, where the great chemist died, and where he for a long time conducted his researches in connection with his cure for hydrophobia.

Dublin Death Rate.

The deaths registered for the week ending Saturday, July 4th, 1903, in the Dublin registration area repre-
sent an annual rate of mortality of 17.5 in every 1,000 of the population. Twenty-six deaths were caused by tuberculosis, 15 by diseases of the nervous system, 26 by diseases of the circulatory system, and 26 by diseases of the respiratory system. Thirty-seven infants died during the week, of whom 25 were under one year old. In two cases the cause of death was uncertified, there having been no medical attendant during the last illness. In the city proper, the death rate in the Summerhill district was 28.0 per 1,000, in the South Earl Street district 26.8 per 1,000, and in the Peter Street district 22.4 per 1,000.

The Supply of Vaccines in Scotland.

A movement has been set on foot to secure the establishment of a vaccine institute in Scotland, and a deputation is to be received by Lord Balfour to-day to urge the importance of this step. A memorial signed by the representatives of the various universities, teaching and examining bodies has already been for-
warded to Lord Balfour, who is stated to be sympa-
thisetically disposed towards the project.

Royal University of Ireland.

The following have passed the first Examination in Medicine (Summer Session):

The undermentioned candidates have qualified on their answering to present themselves for the further Examination for Honours in the subjects set after their names. Those qualified in two or more subjects may represent themselves for the Honour Examination in all subjects):

Thomas Arnold (Chemistry), Ralph N. Berman (Botany), William Bradbury (Physics), Edwin B. Brooke (Physics), Matthew P. Crymble (Zoology and Physiology), Joseph P. Carolan (Chemistry), David S. Clarke (Botany and Physics), Robert J. Clarke (Physics), Arthur J. W. Compton (Physics), Alexander W. Connolly (Zoology), Mary Cowhy (Botany), Cecil F. Crymble (Zoology and Physiology), John Hughes (Zoology, Chemistry and Physiology), Marshall F. Huston (Botany, Zoology, Chemistry and Physics), John J. Kearney (Botany, Zoology, Chemistry and Biology), Robert G. Kess (Chemistry), Richard R. Kirwan (Zoology), James B. Lapsley (Botany and Physics), Morgan Leave (Botany and Zoology), John E. A. Lynham (Physics), John S. McCombe (Botany, Zoology and Physics), George H. Martin (Botany), Patrick C. O'Donnell (Chemistry and Physics), Patrick O'Hart (Zoology and Chemistry), Herbert H. Prentiss (Zoology and Chemistry), Daniel T. Sheehan (Botany and Zoology), Michael Waldron (Physics).

Trinity College, Dublin.

The following candidates, during Trinity Term, 1903, passed the examinations hereunder:—

Physics and Chemistry.

Physiology and Chemistry.

Physical and Chemistry.

Botany and Zoology.

Notices to Correspondents, Short Letters, &c.

Correspondents requiring a reply in this column are particularly requested to make use of a distinctive signature or initial, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Correspondents are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

Original Articles or Letters intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

The Legion of Honour and the French Hospital.

To the Editor of the Medical Press and Circular.

Sir,—Last Tuesday at the Council (on which we were all delighted to see the President of the French Republic present the Cross of the Legion of Honour to Mr. Edmund Owen. May he be allowed, however, to address a few sentiments to my having given my honorary services for more than twenty-seven years to the Institution, whereas Mr. Owen has only been attending the Hospital a little more than a half years. Surely my services merit at least a similar recognition.

I remain, Sir, yours truly,
H. de Mere, Surgeon to the French Hospital.
18, Nottingham Terrace, Regent's Park, N.W.

[It must be obvious that there are services and services, and the benefits conferred by the surgeon are not to be gauged by mere seniority.—Ed.]

F. L. S.—The matter is under consideration.

Ferrars, C.—Regret we have not the particulars you desire.

Dr. Jardine (Glasgow) is thanked.

Mr. W. S. T. will see the subject is referred to in our editorial column elsewhere.

An Aid to Diagnosis.

Doctor: "James did that lady in the washing-room come in her own carriage this morning!" Servant: "Temeraire, sir." Doctor: "Thanks. I couldn't tell from her dress whether to prescribe three months at Harrogate or sulphur-and-treadle."—(C. & G.)

Mrs. J. G. Balsan.—We are in receipt of your communication of the 4th inst. in reference to the paragraph entitled, "Health and Beauty Doctor," but we regret that your request is not one which we deem it desirable to comply with.

Dr. W. D.—The form in which you have made your communication presents problems for us. We can only discuss principles, not persons, at any rate, in this connection.

G. S. A. (Belfast).—We do not see anything objectionable in the draft of letters which accompanies your letter. A good deal would, however, depend on the terms of the "covering" letter. Your own conscience should guide you in the matter, assuming that you have at heart to conform to infra-professional etiquette.

Penny "Cure."—The latest variety of the automatic machine to be installed in Paris is named "Everybody's Doctor." By putting a penny in the slot one will be able to obtain remedies for headaches, colds, and the less serious ailments.

Appointments.

Blumflot, J., M.D., Cantab., Honorary Anaesthetist to the National Dental Hospital, Great Portland Street, London.

Booth, A. W., M.R.C.S., Consulting Medical Officer to the East Foorhouse and Hospital, Dunleith.

Kilgour, J., L.R.C.P. and L.S.A., M.R.C.S., Medical Referee under the Workmen's Compensation Acts, 1897 and 1900, and to act for the County of Kildare, Ireland.

Scurr, Robert Gillespie, M.B., C.M. Edin., Member of the Court of Examiners for the University of St. Andrews, Edinburgh.

Taylor, Dr. D. C., M.R.C.S. Eng., L.R.C.P. and L.S.A., Medical Officer and Public Vaccinator to the Slough District of the Bristol (Lincs.) Union.

Vacancies.

Guy's Hospital Medical School.—Gordon Lectureship in Experimental Pathology. Immediate applications to the Secretary of the Board of the Hospital.

Victoria Hospital for Children, Chelsea, S.W.—Medical Radiographer. An honorarium of £31 10s. per annum is given. Applications to the Secretary.

County Asylum, Whittington, Preston, Lancashire.—Assistant Medical Officer to act also as Pathologist. Initial salary £175, with apartments, board, washing, and attendance. Applications to the Medical Superintendent.

Chelsea Infirmary.—Second Assistant Medical Officer. Salary £20 a year, with board, apartments, coal, gas, washing, and an allowance of £210 a year (optional) in lieu of beer. Forms of application will be supplied by the Clerk to the Guardians.

Sheffield, The Royal Infirmary.—Honorary Surgeon. Applications to the Secretary.

Noble's Isle of Man General Hospital and Dispensary, Douglas.—Resident House Surgeon. Salary £25 a year, with board and washing free. Applications to Dr. Grigg, Hon. Treasurer, 16, Athol Street, Douglas, Isle of Man.

Grove Hall Asylum, Roy, London.—Assistant Medical Officer. Salary at the rate of £100 a year, with board, furnished apartments, allowance, and washing. Application to the Medical Superintendent.

Ancora Hospital, Manchester.—Resident House-Physician with charge of medical school. Salary £100, with board, as. Applications to Samuel Bain, Secretary.

Eastern Counties Asylum for Idiots, Colchester.—Resident Medical attendant. Salary £100 per annum, with furnished apartments in the Asylum, board, and washing. Applications to John C. Turner, Superintendent and Secretary, Palmer Memorial Hospital (for scoliotic), Jarrow-on-Tyne.—A House Surgeon. Commencing salary £100 per annum (board and residence provided). Applications to the Secretary.

Sheffield Medical Office of Health. The salary will be £700 per annum. Applications to H. Sayer, Town Clerk, at the Town Hall, Sheffield.

University College of South Wales.—Professor of Anatomy. The Salary is £300 per annum. Applications to J. A. Registrar, University College, Cardiff.

Somerset and Bath Asylum, Cotsford, Taunton.—Assistant Medical Officer. Salary £100 per annum, increasing to £200, with apartments, board, washing, &c. Applications to the Medical Superintendent.

Births.

Waller.—On July 7th, wife of Dr. A. W. Williams, of 10, Stamford Road, Brighton, of a son.

Marriages.

Daley.—Walters.—On July 11th, at the Parish Church, Beighton, Frederick J. Daly, eldest son of F. Daly, M.D.R.U.I., of Hackney, to Eleanor, youngest daughter of J. Walters, M.B. Lond., M.R.C.S. of Beighton.

Matthews.—Tweed.—On July 9th, at St. Pancras Parish Church, N.W., the Rev. J. F. Matthews Dunce, son of the late J. Matthews Dunce, M.D., F.R.S., to Katherine Mary, daughter of Mrs. W. J. Tweedie, of Brentford, Middlesex.

Pettigrew.—Troup.—On July 9th, at St. Andrew's Church, Stoke Newington, David Pettigrew, M.B., A.A.B., to Dora Lilian, youngest daughter of Mr. Frederick, of William Troup, 1, Great Eastern Road, London, N.

Payne.—Fox.—On July 8th at St. John's Church, North End, Thomas Fox, of 2, George Street, Alston, to Edith Hawkins, eldest daughter of the late Thomas Fox, of Fortwood Park, Southampton.

Young.—Goodwin.—On July 7th at the Church of SS. Philip and James, Cheltenham, the Rev. A. J. Christopher Young, M.A., Examiner, Pembroke College, Cambridge, son of William Young, Manor House, Drotlow, to Ethel Margaret, daughter of the late Robert Douchney Goodwin, F.R.C.S., of Ashbourne, Derbys.

Deaths.

Knop.—On July 11th, at Church House, Bakewell, Clara Isabel, younger daughter of John Knox, M.D.

Rat.—On July 4th, at Beeches, James Rat, M.R.C.S., formerly of Lowestoft, aged 72 years.

Woodhouse.—On July 5th, at his residence, Ralbusbury, Eding Mead, Wrexham, Wrexham, Robert Hall Woodhouse, M.B., L.S.A., of 1, Hanover Square, W., aged 54.
Original Communications.

ON
LACERATIONS OF THE CERVIX

AND THEIR CONSEQUENCES. (a)

By John William Taylor, M.D., F.R.C.S.,
Professor of Gynæcology in the University of Birmingham. Surgeon to the Birmingham and Midland Hospital for Women.

Although the subject of my paper belongs rather to minor gynæcology, it has an important bearing on what is, perhaps, still the gravest disease to which a woman is subject—I allude to puerperal sepsis—and that, by means of this, laceration of the uterine cervix becomes a not infrequent cause of death.

In most of the septic cases to which I am acquainted, after I summoried an operation I find serious laceration of the cervix, of the vagina, and of the perineum as the result of the infection from which the septic and generally fatal process has started.

That, although this may belong rather to the province of our sister Society than to ourselves, it is well, I think, at the outset of our discussion to recognize its grave bearing on the great issues of life and death, and to see to it that our influence is exerted as strongly as may be on the side of prevention. For there can be no doubt, I think, that certain countries and districts furnish many more cases of this accident than do others, and that its comparative infrequency in any district closely corresponds with the better teaching and practice of the obstetricians of the district. Many years ago when attending gynæco-

logical clinics in Paris, I was particularly struck with the comparative rareness of any severe cervical laceration among the attending patients, and have no doubt that this was largely due to the teaching and influence of those great obstetricians and their assistants who were then doing so much for their specialty in the French capital.

Death, then, as a not infrequent consequence of acute septic laceration of the cervix, and laceration, as a largely preventible accident, are the two points from which I start. But, fortunately, many cases of laceration escape serious sepsis immediately following labour, and heal without difficulty. The greater number of these, however, are in the perineum, are of very little importance, heal in a right direction, and need no treatment. The lesser number are more important: many of them are really ruptures of the lower part of the uterus, they often extend quite above the vaginal roof into the broad liga-

ment of one side; they heal, not by any direct union of the raw surfaces, but by growth of epithelium over the raw surfaces. Consequently, the patient recovers with one or more deep permanent fissures in her cervix, and with cicatrices in the vagina and supravaginal tissues. It is mainly with these that I shall have to deal.

First of all, they seriously interfere with the proper involution of the uterus, and although the patient remains much longer in bed than usual, when she begins to get up the uterus itself is still enlarged and heavy, and the torn cervix is often flabby and gaping. Then, in addition to weight, menorrhagia and backache, which may be put down largely to subinvolution, other important consequences are apt to follow, which I will briefly consider under three heads—

Firstly, as affecting the position of the uterus. Secondly, as affecting the nutrition of the cervix. Thirdly, as affecting the uterine wall at the angle of the tear.

First, then, as regards the position of the uterus.

Let us suppose that the laceration is left-sided, extending into the vaginal roof and left broad ligament.

The uterus, which has formerly maintained a central position in the pelvis, being equally supported on both sides, has lost this support on the left side, and consequently settles down in the pelvis on this side, taking its fresh bearing (on the left) from the highest limit of the tear. With this, the sides of the laceration separate, and some tension necessarily occurs at the angle of the tear. This "dragging" usually causes pain on the side affected; pain increased on standing or walking, or exertion, and relieved by rest in bed.

Secondly. Consequences affecting the nutrition of the cervix.

The gaping of the tear causes exposure of the cervical canal, the cervical mucous membrane becomes mechanically irritated, and much more easily affected by micro-organisms; the cervical glands increase in size, in number and in activity; and an excessive amount of cloudy mucous-purulent discharge hangs about the cervix, or gradually finds its way to the outside surface through the vagina.

In this way, or by more direct infection (after intercourse or miscarriage), some secondary sepsis sooner or later almost always attacks the already irritated cervix. The tear or tears, which already interfere mechanically with the circulation in the cervix, affect the inflammatory process. A subinflammatory oedema is added to the endo-
cervicitis. The assurred and distorted cervix swells. The swelling affects the mucous and submucous tissues chiefly, and these bulge outwards, causing erosion of the mucous membrane. The ducts of the cervical glands become obstructed by the swelling, and the well-known distended follicles, or "ovula Nabothii," form in the substance of the cervix, and are easily felt by the examining finger.

In consequence of the endocervicitis and erosion the cervix around the opening or "slit" of the cervical canal becomes inflamed and red, and easily bleeds on touch. It also becomes tender, pain is felt on coitus, and, because the cervical canal is obstructed either by the swelling or by the discharge, the patient is usually sterile, or, if conception ever takes place the patient is liable to abort.

I need not dwell on this portion of my subject; the changes induced by laceration with chronic cervicitis, the swelling, the erosion, and the erosion are well known to all of us. The process very generally slowly increases until, instead of a recognisable portio vaginalis, we find a florid, spread-out area, the surface bathed in muco-pus with streaks of blood, closely imitating that produced by epithelioma, and occasionally, but very rarely, as in other irritated junctions of mucous membrane and skin, passing into this by almost imperceptible gradations. Such is the picture of a typical cervicitis, the main predisposing cause being the injury and exposure produced by various lacerations of the cervix, the exciting cause being some septic infection of the irritated cervix.

Thirdly. Consequences affecting the uterine wall at the angle of the tear.

In process of time—whether by unequal tearing, or by traction on the torn angle, or by atrophy at the point of flexion—if the laceration be severe (as I have described) the uterine wall at this part is apt to become specially thin and yielding, and on paring it, as in the operation of trachelorrhaphy, it may be found that the uterine wall here is thinner and narrower than at any other part, either above or below the limit of the laceration. This necessarily interferes with the permanent strength and stability of the uterus on the side affected, and with the perfect success of any operation intended to restore the parts to their full natural shape, position and efficiency.

If I now recapitulate the consequences of laceration on which I have lightly touched, I find, first, that those of minor degree have no consequences; and second, that those of major degree, in addition to being a favourite channel of fatal sepsis, may cause subinvolution, serious menorrhagia, uterine descent and flexion (by reason of the injury to the vaginal roof), cervicitis, with all its consequences, pain, usually directly referable to it, abortion, sterility, atrophy of the uterine wall at the highest limit of the tear, and finally (but very rarely) epithelioma. With regard to this last (possible) consequence of neglected laceration, it is reasonable to suppose that it may occur, and I have seen one case, but only one clear case, in which a badly lacerated cervix became carcinomatous.

The frequency of this growth, as a sequel to laceration, has, I think, been much over-stated. As a rule a lacerated cervix with chronic cervicitis remains a lacerated cervix with chronic cervicitis, and does not grow into anything different from this.

On looking over my list and asking myself how far minor surgery can deal successfully with all these troubles, I find a sharp dividing line is drawn between the consequences due to uterine laceration only and the consequences due to injuries extending beyond the uterus.

The subinvolution and chronic menorrhagia, the cervicitis in all its forms and degrees, and weakening discharge being irreparably connected with this, in other words, the troubles due to the uterine lesion and to the uterine lesion only, can all be thoroughly and completely cured by the operation of repair of the laceration, and by this combined with a preliminary curetting. A wedge-shaped excision of the cervix is rather often needed (at the same sitting) before the lacerated parts can be brought together and repaired, and the whole angle of the tear needs, of course, complete excision; but in one way or another it is nearly always possible to reform the cervix, to stop the discharge of years, to cure persistent menorrhagia, and in a fair proportion of cases to restore the patient to good health.

But when there is something more than the uterine lesion, when the injury extends widely into the vaginal roof and broad ligament, then, however perfectly the uterus itself is repaired, there is something still wanting. The faulty position of the uterus, the cicatrix in the broad ligament, the consequent dragging on this, these are still sources of pain and discomfort, and the patient—however perfect the cervix may appear as seen through the speculum—is still more or less unrelieved.

In such cases, at the repair of the laceration I have sometimes tried to re-attach the broad ligament to the cervix at its proper level, but with only partial success, and in the worst of these cases the only thorough relief to be obtained is, I believe, by removal of the uterus.

In one case of this kind in which I was consulted, I found that the patient, a young married woman, who had formerly lived an active and vigorous life, had become a hopeless invalid, unable to do anything, and a hopeless burden to herself and her friends. She had a contracted pelvis, and at her first and only confinement the child had to be destroyed by craniotomy.

An extensive laceration occurred through the cervix into the vaginal roof, and this was directly followed by constant pain and invalidism. There was nothing else the matter, and there could be no reasonable doubt that the laceration was responsible for the pain and disability.

I advised hysterectomy, as I did not think that any simple repair would be so efficient in relieving pain, and the possibility of any recurrence of the danger seemed to call for prevention.

The result has been extremely good. There is no pain now, and the patient is again leading an active and useful life.

Such cases need the most careful diagnosis in the highest sense of the term. Some of the severest lacerations, extending into the bladder and rectum, may cause no pain afterwards, while an aseptic laceration which has healed throughout, but on which the uterus is always dragging, may be a source of constant discomfort. The fixation of the organs in some of the worst cases is undoubtedly a safeguard against pain.
SURGERY OF THE STOMACH. (a)
By DR. E. DOYEN,
Of Paris.

After the first series of operations on the stomach the surgery of the viscus remained long without any further progress being made. The brilliant successes of Billroth, Rydiger, Czerny, and Wecker have been attributed to the growth of the new plasmas that called for them. Not until pylorectomy and gastro-enterostomy were performed for the treatment of fibrous stenoses of the pylorus did the marvellous therapeutic results that were attainable by surgery in the group of non-cancerous diseases of the stomach come to be recognised. Mickulicz and Heinecke made a great stride forward when they, in cases of simple non-cancerous stenosis of the pylorus, enlarged the opening by a longitudinal incision and closed the wound by transverse sutures. Billroth adopted this operation in analogous conditions both of the stomach and duodenum. Withal, the surgeons as a body were unwilling to adopt the operation, even in well-marked cases of stenosis of the pylorus as a last resort, and it was usually postponed until the patient was profoundly cachetic. This timidity and hesitancy was due to the faulty technique of the method adopted in the early days of the operation, which made the result as unfavourable as the operation performed for cancer. When Macewen succeeded in curing stenoses of the stomach, which were not amenable to internal medication, he found that the special indications for pylorectomy and gastro-enterostomy were not clearly understood, and that the mortality from these operations varied from 40 to 50 per cent.

He then decided to determine the indications for operative interference in cases which, until the present time, were ever considered as in the province of pure medicine, and which the physicians were unwilling to hand over to the surgeon.

Secondly, he resolved to arrange the technique of the operations for such grave and painful diseases of the stomach as were unrelieved by internal medication, even though they were not of a fatal character.

Indications for Operation.—The author has vividly in mind severe cases of gastropathy, which determined the death of the patient, during middle age, in which the autopsy showed no trace of ulcer or cancer. The clinical study of a number of cases of ulcer of the stomach and of dyspepsia, accompanied by wasting and cachexia demonstrated to him—

1. That the determination of the character of the gastric secretions gave an indication that allowed of a rational and beneficial treatment.

2. That in the majority of cases the painful phenomena were due, almost exclusively, to the undue retention of the food in the stomach.

3. His first operations confirmed these clinical observations, and led him to the conclusion that—

(a) The pylorus of patients suffering from ulcers in the stomach, or from severe dyspepsia, is in a condition of almost permanent spasm.

(b) Spasmodic contraction of the pylorus produces little by little fibrous induration of the gastro-duodenal sphincter, which in time comes to form a hard ring of six to eight millimetres in diameter.

(c) Atomic dilatation of the stomach does not exist except in theory, and the conception is the result of inexact clinical observation.

A number of patients suffering from ulcer of the stomach get paroxysms of hyperacidity and a sense of weight—the gastric cavity is partially emptied each night about daybreak. These cases of lavage of the stomach remove the doloris; nevertheless, they become thin, lose strength, and become very irritable; the liver, however, are able to digest enough to maintain life; but the food is vitiated by the undigested material in the stomach. The position of the viscus during life is, the author states: the stomach lies with the pylorus as its most dependent point and is undilated unless when it contains food, as he has often seen it, during laparotomy. Gastro-enterostomy in his hands effected the removal of all the distressing symptoms of chronic gastropathy. The pains, the vomiting, the haematemeses, and the dyspepsia ceased. He ascribes the gastric pain in such cases, especially in alcoholics, to the presence of a small, round ulcer near the pylorus or the lesser curvature. Irritation of this ulcer is followed by spasmodic contraction of the pylorus, and frequently by irritation of the mucous membrane. On the disappearance of the ulcer the pains and dyspepsia cease and the appetite returns to the normal. In 1893, after three years' experience of gastro-enterostomy, he formulated the following indications for the operation:

"Every chronic or recurrent ulcer of the stomach, not amenable to medicinal treatment, is producing a serious injury to the economy, and is within the province of surgery."

The indications for operation in cases of cancer and of fibrous stenosis of the pylorus he does not further discuss. The cure is complete when the stenosis is purely mechanical. Even in cases of cancer the operation was practically a cure for four or five years; in one case the gastro-enterostomy prolonged life for ten years. Operation in cancer of the stomach is attended with good results when performed early, when the physicians place the patient in the care of the surgeon without unnecessary delay.

Results of the Operation.—The results of the operation are influenced largely by the time when it is performed, the gravity of the case and the familiarity of the surgeon with the technique of the operation. The amount of vital resistance the patient possesses is an important factor in the case.

Some patients possess an incredible amount of vitality. Cases in which the fatty tissues of the epiploon are cancerous, particularly if the patient is stout, are unfavourable for operation. Non-cancerous patients who have from dyspepsia become cachectic are also unsuitable cases. The results obtained in all cases, including such unfavourable ones as gastric ulcer with haematemesis and oedema of the legs with phlebitis, gave a mortality of from 4 to 6 per cent. The prognosis in cancerous cases is dependent on the extent of the growth and the degree of cachexia present. Taking one with another the mortality oscillates from 15 to 25 per cent. When the stomach is retracted, scirrhus throughout, and deeply adherent, its total excision is more readily performed than gastro-enterostomy.

The author then proceeded to enumerate the different operations that are performed on the stomach, and to describe briefly the technique of each. He enumerated gastro-jejunostomy,
anterior and posterior, gastro-duodenostomy, resection of the pylorus, and total excision of the stomach.

Clinical Lecture
ON THE
INFLUENCE OF IRON UPON
BLOOD FORMATION. (a)

By Dr. MATRAI GABOR,
of Budapest.

Considering the importance of the rôle iron preparations play in the treatment of anaemia and of the neurasthenia usually associated with the former, one cannot wonder that many and varied views are held regarding the absorption and action of iron. For many years iron was a drug much favoured by physicians in the fight against anaemia and chlorosis. Fifteen years ago, however, a notable physiologist, Bunge, sought to depreciate its therapeutic value, holding as his opinion that when good results followed its exhibition they were due to suggestion, reasoning that the iron introduced into the organism could not be found in the urine, and that as the greater part was met with in the dejecta the iron never enters the circulation, but simply passes through the gastro-intestinal tract, and is evacuated without any obvious use to the organism. And he accentuated this view that only the iron enclosed and contained in foods is absorbed and enters the circulation.

At the International Congress held in 1895 in Munich, leading physicians who were also investigators, such as Quincke, Ziemssen, and Baümler, supported by their vast experience, fought against this view, and so a many-sided investigation has been started with the object of ascertaining the fate of iron entering the organism.

Furthermore, noting its course when introduced into the veins, found that the evacuation of the iron takes place through the intestinal tract, and only a trifle is evacuated by the kidneys; further, that the remainder of these iron preparations in the circulation for a lengthened period result in considerable elevation of the iron contents of the liver. But these, particularly the spleen, increase also when the iron is taken into the stomach, as shown in the experiments of Kunkel and Hall on mice and young dogs. These experiments elucidate undoubtedly the theory that iron is absorbed into the blood. The site and mode of absorption were investigated by Gaule, Hochhaus and Quincke, and these declared it to be similar to that of fats, inasmuch as the iron absorbed in the upper portion of the duodenum and intestines by the epithelial cells of the villi is transferred by these into the lymph-channels, and thence into the blood. Lately, we know, from the investigations of Hari, that a part of the iron is absorbed also in the stomach. The place of its evacuation from the blood is, according to the observations of Hochhaus and Quincke, per rectum and cecum. When with the aid of these experiments the place of absorption of the iron, likewise the site of its evacuation, became clear, the question came to the front, in what form is it advantageous to administer the metal—in the form of organic or inorganic compounds?

Only if introduced with foods, we ought to believe, à priori, that the organic compounds, as they are found in foods, are more apt to be absorbed. Under the term of inorganic iron we understand salts which, if brought into contact with sulphide of ammonium, undergo blackening, whereas the organic iron has to be disunited in order to produce the blackening with sulphide of ammonium.

This view is not confirmed by experiment. Hochhaus and Quincke, like Hofmann, worked with the most various organic and inorganic iron preparations, and they asserted that no essential difference exists regarding the absorption of these.

Aberhalden, when investigating the above-mentioned ways of iron absorption (with the aid of sulphide of ammonium) in the duodenum, has found that, apart from the organic or inorganic character of the iron preparations administered, they were always found in the form of inorganic salts.

It seems, therefore, that organic iron must be converted into inorganic before it can be absorbed into the system, as by the experiments referred to only inorganic iron is absorbed. For this ground, and on other later experiments of Aberhalden and Tacquet, the former expresses an opinion that the inorganic iron is that which can be directly converted, and not the organic, as contended by others.

The process by which iron so absorbed enters into the circulation and influences blood formation is not yet entirely clear. As a result of these experiments Hofmann imagines that iron acts as a stimulant upon the blood cells, producing the stable quality of the bone marrow. Others, on the contrary, believe that it enters immediately into combination with the blood. Be the blood ameliorating property of the iron what it may, the counting of the blood cells and the percentage determination of the blood stain makes it clear that in numberless cases in which iron is administered its distinct advantages in chlorosis and anaemia have been abundantly proved.

A few years since the compound syrup of a notable Hungarian druggist, Dr. Egger, enjoyed extensive popularity. It consisted of iron syrup o‘7 calcium, o‘66 potash, associated with hypophosphite acid, further o‘05 quinine, and o‘0005 tincture of nux vomica, is found. As in this preparation the iron is present in an inorganic form, and because according to my experience it never upsets digestion, indeed, on account of the stomatics contained therein rather improving the appetite, I thought it would not be superfluous if I controlled its action also with blood examination, the result of which I give in the following.

It should be remarked that in the determination of the haemoglobin I used the decidedly more accurate, though rather more troublesome, method of Fleischl-Mischer, being more perfect because it renders the measuring of the blood quantity more accurate; further, because every single determination is established with two vases, of different size, with the aim of reciprocal control, the old method of counting being apt to give erroneous ideas on the haemoglobin contents of the blood. If, for instance, we see stated that the haemoglobin is 45 per cent., those not often occupied with blood examination may believe that this blood contained really 45 per cent. haemoglobin, although it was in reality stated that this contained only 45 per cent. of the normal haemoglobin contents,

(a) Specially reported for The Medical Press and Circular by Dr. Adolf Keil, of Budapest.
the quoted number indicating only the relative haemoglobin contents. It is, therefore, much simpler to give the absolute haemoglobin value in the first instance, or the reckoning of one value against another can be made very simple, according to the following table:

\[ X = \frac{14 \times R}{100} \]

According to T. G. Otto the blood of a healthy man contains 14 grammes of haemoglobin.

\[ R = \text{relative haemoglobin value.} \]

\[ X = \text{absolute haemoglobin value.} \]

Taking, for example, 45 per cent. relative haemoglobin contents:

\[ X = \frac{12 \times 75}{100} = 6.75\% \]

is the absolute haemoglobin.

The cases wherein I experimented with the Egger compound syrup are as follows:

**Case I.**—K. E., aged 26, a female teacher, has been a few years anemic but for the last half year she has wasted considerably, and has been very pale, lacks appetite, suffers from palpitation, headache, constipation, and vertigo. She is very excitable and neurasthenic. During the first blood examination she fell from the chair in collapse. She came under treatment on September 29th. Three teaspoons of Egger syrup in half a glass of water after meals were taken daily. In two weeks the headaches and vertigo had already disappeared, the appetite also had improved considerably. At the end of the first month her appetite became satisfactory, her face had an animated and fresh appearance, and parallel with this there was elevation in the number of the red blood cells. Since this time the patient has taken daily three tablespoons of the syrup. At the end of the first month neurasthenia had decreased, and her face took more colour. She continued this treatment up to December 28th, when the number of the red blood corpuscles became well-nigh normal, the patient bodily and mentally fresher; appetite and stools normal.

**Case II.**—O. L., aged 20, suffered from chlorosis for a few years, her menstrual periods had not presented themselves for months together, frequent headaches and vertigo troubled her, she got easily tired, walking upstairs only with effort. There was indigestion, loss of appetite, and constipation. The visible mucous membranes were conspicuously pale, heart sounds weak, over the left jugular vein distinct murmur was heard. She underwent treatment on September 29th, and takes daily three tablespoons of syrup hypophosph. compositi sec. Egger. On November 15th the headache, vertigo, and appetite had already improved, the quantity of blood pigment, likewise the number of red blood cells, have been considerably elevated. From this time the patient took, three times daily, a tablespoonful of the syrup. On December 23rd the appetite was good, stomatotic pains after meals had subsided, the mucous membranes were more coloured, the murmur heard over the jugular vein had ceased, and the patient was able to take longer walks without getting tired.

**Case III.**—T. T., aged 13, schoolboy, had been considerably emaciated and anaemic on account of a long-standing colitis. After subsidence of the diarrhoea, the patient began to take the syrup, nominally three teaspoonsful daily. Scarcely six weeks elapsed and the boy's face assumed a healthy colour, weight increased, and the haemoglobin contents of his blood became much greater, likewise the number of red blood corpuscles had conspicuously increased.

**Case IV.**—O. T., a girl, aged 18, pupil at a high school, anaemic, no appetite, and complained of headache, constipation, and vertigo. She went treatment on September 29th, 1901. In two weeks the subjective complaints already were set aside. She has since taken three times daily a tablespoonful of the syrup, and in two months was quite well.

**Case V.**—G. Gv., aged 28, lawyer.

**Case VI.**—C. O., aged 21, a clerk.

**The Out-Patient Departments.**

**The Cancer Hospital.**

*Under the Care of Mr. Cecil H. Leaf.*

The following three cases are shown to illustrate the connection between local injuries and the production of epithelioma:

**Case I.**—D. R., a healthy-looking man, aged 60, attended as an out-patient in May, 1902. On examination, it was found that he had a ragged, somewhat irregular ulcerated surface at the back of the right thigh, which measured some four or five inches in its transverse, and about three inches in its vertical diameter. Round the ulcerated portion there was a considerable quantity of dense fibrous tissue; the edges of the ulcer were raised, but not much everted. From its appearance and from the manner in which it gradually extended, there could be no doubt as to its epitheliomatous nature. On a similar place on the right thigh there was an area of fibrous tissue, but nothing suggestive of epithelioma.

The following is the patient's history: Thirty years ago he
was working with Whitehart varnish and methylated spirit (Whitehart varnish is composed of shellac, best resin, and best gum, and is of a superior quality). When the phalanx of the right thumb got burnt, he thought he might have been being burnt on his right than on his left thigh. After the accident, he was taken to a hospital, where he remained six months. During this time the sore on the right thigh was clean. Six months afterwards, however, it had healed entirely, and nothing remained but white scar tissue. Twenty years after the accident, the white scar tissue began to "grow out like a peach-stone," and the raw surface soon afterwards began to extend. Ten or thirty years after this, or thirty years after the accident, he again went to a hospital, where, after the growth had been microscopically examined and pronounced to be cancer, amputation of the thigh was proposed. This, however, the patient refused. After his admission into the Cancer Hospital, the question of amputation could not be entertained, owing to the impossibility of obtaining sufficient healthy tissue to form the necessary flaps. The X-rays were tried, but without the slightest benefit. In spite of all treatment, the ulcer gradually extended, and no doubt could be entertained as to its malignancy. Mr. Leaf remarked that the case was one of great interest in showing the limited relapse between the irritable cause and the subsequent development of the epithelioma. It was further of interest in showing that the same cause had produced an epithelioma on one side and simple fibrous tissue on the other. This, he thought, was probably due to a difference in intensity.

Case 2.—M. B., at 52, attended as an out-patient on January 23rd, 1903. She complained of discomfort in the right side for some time. On examination it was found that she had a large epithelioma, about three inches by three and a half inches, and involving the two labia of the left side. It extended upwards into the posterior wall of the vagina for about one inch. The growth was excavated. Two of the horizontal inguinal glands on the left side were felt to be considerably enlarged. The history of this patient was as follows: In her last confinement, twenty years ago, she had a very tedious labour. According to her own account, there was considerable difficulty in the delivery of the head and shoulders. Two years afterwards a lump was noticed in the left labium; this growth did not bleed to death from post-partum, and not a large, and was certainly in a very bad condition when he arrived. But palpation proved that the uterus was well contracted, and he found that there was a very extensive laceration of the cervix. By separating the edges of the laceration with tenacula he was able to discover and suture the bleeding point with silk-grass-gut with perfect success. In similar cases of hemorrhage it was sometimes sufficient to use the hot-water douche, or at most to apply a tampon of perchloride of iron solution on cotton wool, but he thought it better surgery to secure the bleeding vessel and sew up the laceration at once; indeed, he was not sure that even when there was an extensive laceration of the cervix it could not be repaired immediately. With regard to the remote consequences, it was true that when lacerations extended above the vaginal roof and were not properly treated, sepsis was very liable to occur, with the danger, even if the patient recovered, of adhesions contracting and dragging the uterus over to the side affected, and of various ill results afterwards, but in his experience the great majority of tears in the cervix, especially of those affecting one side only, required no treatment at all. When the laceration was extensive it might lead to the evil consequences mentioned by Professor Taylor. One of such consequences, the thinning of the uterine tissue in the neighbourhood of the wound, had not been brought under his notice before, but would probably account for an accident he had lately had to deal with. A lady from the Cape, who had had an extensive unilateral laceration of the cervix, the edges of which had healed perfectly—nothing else appeared wrong with the cervix and there was no distension of the glands—consulted him for bulky subinvolved uterus with menorrhagia and leucorrhoea, and he recommended that the uterus should be dilated and a cure performed. The dilatation was conducted with ease, and was almost completed, when, on withdrawing one of the higher dilators, which had been passed quite easily without the slightest extra force, there was furious haemorrhage. The uterine artery, to his surprise, had little to his horror, had been torn. He was able to seize the bleeding point in a pair of long pressure forceps, which were left on for forty-eight hours. He curedt the uterus, and the patient did perfectly well.
Mr. W. D. Spanton said that the recognition of the importance of laceration of the cervix had been of comparatively recent date. No mention was made of it in the books of days, or even in monographs, and frequency now might be due in part to the freer use of instruments, as well as the impatience of the younger race of practitioners. They now had to deal with lacerations of uterus and perineum, where formerly they had to remedy fistulas of various kinds caused by pressure from undue delay. The chief significance of lacerated cervix lay in the fact of its capacity for developing troubles in the future. Recent lacerations were sometimes a grave source of trouble. He had lately been asked to see a woman in good circumstances on whom forces were used, resulting in a tear of the cervix so deep as to lead to septic cellulitis, and death within a week. The practitioner in charge had sutured the tear in the perineum, but had ignored the graver mischief higher up, which led to the patient's death. Such calamities might, of course, happen to anyone, but they ought to be recognised and properly treated at once. At the same time he dissented from the opinion of those who would stitch up every laceration immediately. The slighter ones did no immediate harm, and might safely be left. The more serious ones, however, might prove as soon as recognised. He had seen several cases where a lacerated cervix had resulted first in chronic hyper trophy of the lips, and afterwards in malignant growth, and he had come to the conclusion that a considerable proportion of the cases of epithelioma met with had their origin in this manner. He need not speak of the minor troubles, such as chronic cervical metritis; they were well recognised, and known to require active treatment. Except in the early stages, palliatives did not avail much, and he always now advised and relied upon more active measures, and in the whole course of his experience of a very large number of such cases, he had found that all such cases ought ever to occur when proper precautions are taken. In those cases in which there was a simple laceration with ectropion he found Emmett's operation the best; but when the lips were large, whether from simple hypertrophy or glandular falseness, by far the best method was to excise an ovoid wedge from each, carrying the incisions laterally through the densest tissue of the tear so as to leave the mucous lining practically intact, and not longer than a week, each lip being left on either side. This method he found gave the best results. In women past the menopause it was far better to excise the whole of the lower portion of the cervix and make a stump of the body, for whom he had done this about ten years ago, whose cervix, according to the microscopic report, was undergoing degenerative changes, described as very suspicious, recovered completely and never had further trouble. Details of such cases were recorded in such a Society; one rather aimed at expressing conclusions definitely arrived at after a long and varied experience. He was firmly convinced that much harm was done by tinkering, and the safest as well as the quickest method of curing the after-results of a lacerated cervix was to excise all unhealthy tissues and replace them, as far as possible, by others from the immediate neighbourhood, which were in a normal condition.

Mr. Bowrman Jessett said it was an interesting question whether lacerations of the cervix were more common now than formerly. In his earlier years, when in general practice, he did not remember having had to deal with a single laceration of the cervix, though he must have attended about 1,500 cases of midwifery. But in that large number of cases he did not apply the forces more than half a dozen times. He shared the view of Mr. Spanton that practitioners being more in a hurry than formerly, or perhaps because they were more adept with the instruments, they apt to apply forces and deliver the baby as quickly as possible, there were more lacerations of the cervix than there used to be. His own experience in regard to epithelioma differed from Professor Taylor's, for he had in a considerable proportion of cases of that disease found that it had been preceded by laceration of the cervix, but he could not assert that the laceration was the cause of the epithelioma. He thought if these injuries were detected, and when deep were sutured at once and kept aseptic, every extent could be avoided. Complete hysterectomy seemed to him to be rather a radical measure, but in several cases of deep laceration he had performed supravaginal amputation of the cervix with perfectly good results. In women before the menopause some care was required to keep the canal open afterwards.

Dr. T. A. Helme warmly acknowledged the interest of the way in which he had been called upon to bring a rather hackneyed subject before them in his very able address, but could not sympathise with the views expressed, for, as far as he was concerned, he had to a great extent relegated vaginal lacerations and the tinking operations done for them to the limbo which had received the éclat and old-fashioned clump for hysterectomy. Professor Taylor had drawn a harrowing picture of the ills that might result from tears in the cervix, but in his opinion the cervical lacerations were merely antecedents, not causes, and there was little use in locking the stable door after the horse had been stolen. He thought the views increased that such as childbirth, but not that they might cause subinvolution or displacement of the uterus; and that lateral flexion of that organ occurred after tears of the cervix, in his experience it had been not towards the side of the tear, but in the opposite direction. He attributed not to the tear, save for so much as the tear preceded the subsequent inflammation in the cellular tissue, which was the real mischief, and he could not see that any good would be done by stitching up the tear afterwards. He had never yet been able to satisfy himself that any evil followed a laceration of the cervix which was allowed to heal in the usual way, not by union, but by covering. He was convinced that mere laceration of the cervix was in itself of no importance, and that it did not require operation. The evils that might ensue he attributed to infection. He agreed with Dr. Duncan that severe haemorrhage after labour might be caused by deep laceration of the cervix, and in one instance of such he stitched up the cervix, when the woman was almost dying, with silver wire; the wire was removed at the post-operative examination, and a satisfactory result was obtained.

It was not laid on the primary results of laceration; he did not advocate looking at the cervix after every labour, and stitching it up, normal tissues being combined with ill-health, the patient should be examined and steps taken to relieve her. Inflammation, when it followed laceration of the cervix, was not limited to the cervix, and even amputation left the mischief behind. It might be one's duty, as had been necessary in many cases already, to remove the uterus to give the patient a chance of health.

Mr. Skene Keith thought that Professor Taylor might perhaps have been led to advise the removal of the uterus in cases of extensive tears of the cervix because he had not quite realised the absolute necessity, when operating for the repair of a laceration, of removing every atom of cervical tissue which, if not done, would inevitably be done without causing much haemorrhage, but he did not agree with Dr. Helme that such operations could be termed "nicking" methods; he had known instances as formidable as removal of the entire uterus.

(On the next page, Dr. Helme explained that he spoke with regard to results only. It was the gravity of the operation compared with its possible advantages that he objected to.)
woman would within a comparatively short time regain
her health, and very possibly conceive. Even in cases in
which the ovaries had suffered and their removal
been advised, he had been able to put the woman right
by attending to the cervix in the manner he had de-
scribed. He had no doubt that the rupture of the
united laceration described by Dr. Duncan was due to
the presence of cicatricial tissue. He had not for a long
time had much experience of midwifery, and could say
little of the results of immediately stitching up a
laceration. A general practitioner, with no one but a
nurse to help him, and who did not have chloroform, could
be expected to do such an operation as the repair of a
torn cervix at the end of a probably long confinement.
Under such circumstances he thought it would be
better to undertake it. The relation of cancer to laceration
of the cervix was not determined, but he had never seen cancer in a virgin uterus.

Dr. Macnaughton-Jones said that there was a point
with regard to diagnosis worth drawing attention to.
Many lacerations escaped detection owing to the
examination being made with Fergusson’s speculum,
which compressed the lips of the os together. To see
the extent of the laceration a Sims’ speculum, and
hooks to separate the edges of the laceration, would
be necessary. It should not be forgotten that the clinical
importance of laceration of the cervix was fully recog-
nized and insisted upon by the older obstetrical authori-
ties. Macnaghton-Jones, Hamilton of Edinburgh, Collins of Ireland, had specially referred to them.
The negative view of the influence of laceration was
represented in its extreme shape by Noeggerath, who
denied its bearing on conception, as well as almost all
the clinical consequences which were usually believed
to follow on the lesion. It was not, however, to be
supposed that authorities such as Mundé, Emmet, and
Thomas in America, or Schroeder in Germany, with
all their great experience, were mistaken as to such effects. He (Dr. Macnaughton-Jones) was speaking of serious lacerations such as those Mr. Taylor had referred to. There could be no doubt that associated
with these lacerations of the cervix were found
retroversion, subinvolution, hyperplasia, endometritis,
erythema, and ecchymosis. Relaxation of the uterine
supports, associated with the general flabbiness of the uterus, produced the displacements. The characteristic appearances of the cervix graphically
described by Mr. Taylor were familiar to all, and
haemorrhage or menorrhagia was no infre-
quent result of the cause of laceration; it
should be remembered that it followed even in the
most experienced hands, and was not necessarily due to
instrumental delivery. In view of certain conse-
quencies of the lesion, he maintained that operation was the only satisfactory treatment, and
that in the graver cases amputation of the cervix was
called for. Palliative treatment by tamponning with
ichthyol and glycine, or glyco-thymoline, while it
might benefit some milder cases, had no effect on the
more serious. As to carcinoma, though he had only
seen two cases in which it had followed upon extensive
laceration, it could not be denied that extensive
erosions or defects of the cervix predisposed to the subsequent
malignant degeneration. The scar tissue referred to
by Dr. Skene Keith compressed and obliterated the
vessels and glands of the cervix, while the compression of its
surface undoubtedly led to reflex neuroses, and it
was not possible to speak definitely of the effects of laceration on subsequent pregnancy and labour, but
that it must have some effect on cases of this kind. He
did not think that, save in the case of hemorrhage, it
was well to interfere at the time of labour with the
laceration, but he thought it was a moot question if
it would not be advisable within a given time after
labour, when the delivery was instrumental or in
primary, always to make an examination to ascertain
the condition of the uterus. The discussion was one
which would prove useful by directing renewed attention
to the consequences of a lesion which interferes with the
function of the uterus, and which practitioners had
constantly to treat.

Dr. Mansell Moulin agreed with the opinion that
had been so generally expressed that laceration of the
cervix, in itself, was of little importance; still, it was
often complicated in a way that called for active treat-
ment. One of its most frequent complications was
an inflammatory disease of the adnexa with perimetry-
itis. Quite recently he had had to remove the ovary and
tube from one side of a patient on account of inflam-
matory trouble following laceration of the cervix, which
occurred six years ago. Another condition which
called for interference was ecstropion of the mucous
membrane, for which Emmet’s operation appeared to
be the most beneficial treatment. There was no evi-
dence to show that laceration led to the more than
once he had seen such disease of the cervix
within a year of Emmet’s operation, but that merely
showed how difficult it was to diagnose malignant
disease in its early stage.

Mr. George Keith concurred with what had been
said about the absolute necessity of removing all
cicatricial tissue. Occasionally, when it had been
necessary to follow it up very high, he had known the
patient, on the evening of the operation, to become
suddenly very ill, with a quick pulse and subnormal
temperature, probably because the peritoneum had
been caught in the suture; at all events, all the symp-
toms disappeared in an hour or two after the top
stitch had been removed.

The President thought the discussion had been a
most instructive one, and it would be an encour-
gement to those practising midwifery to know that in
the examination of so many of the cases dealt with
provincial as well as metropolitan, lacerations of the
cervix, unless they were extensive, were not generally
followed by mischief. But it should not be accepted
that the consequences of a laceration were to be abso-
lutely measured by its depth. Sepsis might follow
a small tear and give rise to most serious trouble. The
presence of scar tissue might lead to ecstropion, and
then the lips of the uterine wound might be deprived
of the power of inhibition lost, conception would be impossible. Under this condition Emmet’s operation was a most valuable
proceeding. There were other conditions following
laceration in which operation was not absolutely re-
quired, as the tear was not a deep one. He entirely
agreed with Mr. Skene Keith in attributing persistent
backache and bearing down to the presence of scar
tissue, and, when the knife could be dispensed with,
very great benefit might be derived from the local
application of potassa fusa. This was better than the
actual cautery, the action of which was limited by its
own scar, whereas, under the action of the caustic
patch when the outer sheet of the scar was pierced, the
scar was pressed forwards by the contraction behind it, and by successive applications could be
destroyed as completely as necessary. There was
no doubt that the adnexa might be involved in the
inflammation set up in the cervix and uterus. On the
whole, he thought that after the discussion that
evening, the conclusion must be that lacerations of the
cervix, though frequently giving rise to no serious
trouble, were by no means unimportant, and that
their effects upon the patient’s local and general
condition should be carefully watched, with a view to
treatment according to the indications of each in-
dividual case.

Professor Taylor, in reply, explained that as the
immediate results of laceration were rather obstruc-
tional than gynecological, he had not dwelt upon them, but,
of course, serious hemorrhage after labour was often
due to a torn cervix. In a small cottage with poor
light and insufficient help it might be impossible
for Dr. Duncan to do as Dr. Duncan had done, and secure the bleeding
point, but one might then sometimes stop the hemor-
rhage by carefully applying a voilesia, which might be
left in position for twenty-four or thirty-six hours. It
had been well brought out in the discussion that lacer-
ation of the cervix was to a very large extent preventible,
and though, as Mr. Spanton pointed out, we did not
now so often as formerly see some of what we thought there was in the midwifery
practice of the present day too great a tendency to
hurry. He quite agreed with those who said that minor lacerations of the cervix were generally unim-
portant and with Dr. Helme that trouble after a
laceration was largely due to sepsis, either primary or
secondary. But deep laceration of the cervix ma-
terially altered the circulation of the blood in the part,
and the inflammation which occurred in such a case
came entirely from the brain attacked one in which the blood-vessels were controlled by
the integrity of the tissues. Therefore, while admit-
ting that the sepsis was the most important matter, he
held that the laceration in the cervix should be re-
paired, and he fully recognised that if cicatrisation
should be removed; indeed, he had said in his paper that it should be removed widely from the tear.
He thought that as diagnosis became more accurate,
fewer cases would be met with in which it seemed clear
that epithelium had followed directly upon laceration
of the cervix.

THE GENERAL MEDICAL COUNCIL
OF
EDUCATION AND REGISTRATION.

SPECIAL SESSION.

FIRST DAY.—WEDNESDAY, JULY 15TH.

Sir William Turner, F.R.S., K.M.G., President, in
the Chair.

The President, in opening the Special Session, re-
marked that, having been found impossible to fully
consider all business brought before the Council last
May, extra meetings were found necessary for the con-
sideration of a report by the Education Committee,
which had already presented and entered in the Minutes of that year the returns from teaching institutions furnished by the Conjoint Examining Board in England; also for con-
sideration of reports on the inspection of the primary examination of the Conjoint Examining Board on
the Royal College of Physicians, the Royal College of
Surgeons, the Apothecaries Society, and the inspection
of final examinations of Oxford and London Universi-
ties. After making a few suggestions as to the mode of
proceeding in dealing with the questions under con-
sideration, he called upon

Sir John Tuke, who said that, in asking the Council
to adopt the report of the Examination Committee, they had considered it duty to summarise the reports laid before them. It had been concluded unanimously in 1890 that the curriculum should ex-
tend over five years of medical study, on the under-
standing that the young graduate should be admitted.
That plan had been thirteen years been fully
acted upon, but in 1893 the first note of discord had
been struck. The regulation of the Conjoint Board
authorised the completion of these studies before
registration, but this was done without reference to
the General Medical Council, which Council met and
agreed that such studies antecedent to registration
might be accepted. In every way the Council had made
enquiries, but the latter had stuck to their legal rights instead of
yielding in the least in order to promote the uniformity of
medical education. When that Board thus set aside its system, they had acted without due inquiry, and it had been shown that
although such institutions possessed laboratories and
teachers, yet the scientific instruction did not receive proper attention. The Board had an indication
of the time to be spent weekly on this branch of
study, but fifteen hours were given as the minimum.
After speaking on one or two desirable changes, Sir
John Tuke added that the dispute had been going on
for ten years, and all necessary steps prescribed by
law had been taken by the Council. They had now to
determine their position, and to do so they must make
representations to the Privy Council. If that Council
were of opinion that they should base all their
actions on the Council were in the
wrong, that would be an end of the matter.

A motion that the report of the Education Committee
be adopted was then proposed by Sir John Tuke,
seconded by Dr. Bennett, and carried nem con.

Mr. Bryant then read the comments of the Ex-
amination Committee on the report by the inspectors
of the examinations in chemistry, physics and biology.
In which it was stated that at the examinations of July
and August, 1902, sixty-five candidates had pre-
sented themselves in biology and ninety in chemistry
and physics, all the examinations being oral. The pro-
cedure which the visitors condemned as ill-adapted
to elicit "whether a candidate had been properly
taught or merely crammed," and they gave it as their
opinion that "the examination by trying out was an
element of weakness in the particular instances
under consideration." To which the Royal Colleges
replied, that with a wide experience of biological ex-
aminations they considered "the present method was
that most suited to the circumstances." With regard
to chemistry and physics, ninety-five candidates came
from medical schools, of whom 69 per cent. passed and
30 per cent. failed; fourteen candidates came from
other schools, and of these 50 per cent. failed. Mr.
Bryant's opinion the practical examination was
well conducted, but the syllabus was described by
the visitors as "extraordinarily defective alike in matter and
arrangement" and that the candidates were "so badly prepared that a higher standard than the one
used would have led to the rejection of the majority of
them," and the main part of the practical ex-
aminations was not scientific, being no test either of sound principles or of practical efficiency.
Mr. Bryant then commented on the expressions made
use of, adding that observations had been made by
visitors, but he (Mr. Bryant) had not been allowed to
offer anything in the way of explanation. The ex-
aminors did not look upon the subject of biology in
the same light as the visitors, but considered the pre-
rent mode of conducting the examinations particularly
well adapted to registering students.

Sir Victor Horsley wished to draw attention to a
certain statement which, if taken in full, seemed
extremely considerable, but if it were asked what the
words really meant a different conclusion would be
arrived at. The phrase ran that "the present mode
of conducting the examination was that most suited to
the circumstances." What were the "circumstances"?
He had written to the examiners, who had referred him
to the Secretary of the College. He had written to
the President of that College, and the answer might
be interpreted that the educational standard of the
candidates was so low that the examination was very
well suited to the knowledge or, perhaps, to the
ignorance. It was not quite fair for the representative
of the College of Surgeons to represent to the Council
that gentlemen who were first-class teachers of biology
had said one thing while meaning another.

Dr. Winkle remarked that he would like to comment
on the curious fact of the chairman of the Ex-
amination Committee moving the adoption of the
report in language which damned that report. He
(Dr. Winkle) recognised the very high character of
the four examiners, and had they said that the ex-
amination was excellent he would have adhered to
the views he had previously expressed, in that it was
suited to a number of boys ill-educated at school; but
to say it was a good examination was absurd. The
fact that successes had been gained at the Army Final
had very little bearing on the examination taken.
There were such gentlemen as Army coaches, and the
effect of these gentlemen supplementing the work done
at other institutions did not affect the case. Dr.
Windle also objected to the wording of the report
where it was stated "that the visitor and inspector
had made the following improvements in the admisions." Why "admissions"? when it was supposed to be a statement of
fact? With regard to the study of biology, it was
stated in the report that the "smearing of knowledge"
was the result of which all the students should be quits.
But biology was useful as an introduction to the
methods of observation which were the foundation of
physical and natural science. They (the Council) would suggest a short practical examination as advantageous. If cutting sections took a long time it was the more necessary to begin early. Nothing was more necessary than a farseeing "cramming" more than practical tests. There should also be a written paper and a short oral examination on the top of it. Speaking of the examination services, Dr. Windle went on to say that when he found the Joint Board it was nothing less than a farce, throwing dust in the eyes of the public. Matters were much better in Scotland and Ireland. The practical part of chemistry also was extremely important, tending to usefulness in manipulation. They had no oral examination in chemistry, though there was one in the Society of Apothecaries and in Scotland and Ireland. It was disturbing also to find signs of such bad preparation on the part of students the visitor and inspector found it "difficult to understand why some, the depths of whose ignorance was almost unfathomable, were ever allowed to present themselves for examination.", and little seemed to have been retained of the first year of study. No good conclusion had been arrived at with regard to the best methods of study. It would be better to set aside disputes in the curriculum and agree to a curriculum.

Dr. Payne said some conclusion ought to be come to with regard to the number of subjects to be studied, and how far the year of scientific knowledge was to be separated from anatomy.

Mr. Tichborne urged that the knowledge of chemistry should be developed; hitherto it had been kept down to the standard of candidates, and he urged that qualitative analysis was extremely necessary. He had passed medical men carrying out bacteriological investigations, and he had not been favourably impressed owing to the display of such a lack of knowledge in manipulation.

Dr. Norman Moore thought the Council should bear in mind that they were considering the best way of beginning the education of medical students. Biology might be ruled out, but physics was a very necessary subject. How much of each subject should be examined was a matter for thorough discussion, but general arrangements for the rest of medical education would cause any arrangements to fluctuate. Speaking of the Joint Board, he said that the criticisms and suggestions of the visitor and inspector were under consideration by the Royal Colleges. The Council took one view concerning places of study, the Royal College of Physicians another. He maintained that the Council had no right to enforce its regulations as to the choice of institutions where instruction might be imparted.

Dr. McVail remarked that Dr. Norman Moore had misunderstood the report. The report was to be a just one, that he had no fault to find with it, yet he refused to vote for its adoption. Moreover, the report was that of the Examining Committee and in no way dealt with questions of medical politics, but Dr. Moore had introduced that subject. Instead of devoting his attention to the report he went on to observe that the Council was a body well fitted to give opinions on the curriculum, and his College (of Physicians) would give any motion adopted by the Council its "careful consideration", but were in no way bound by their charter to do more. The Council decided that the curriculum was insufficient, but further action had been stopped to allow of a visitation under Section 18 of the Medical Act, and they were now considering the results of that visitation. Had Dr. Norman Moore and Mr. Bryant nothing to tell them of any chance of agreement, or were they (the Council) to wander eternally round the same path? He, personally, would exceedingly regret their quarrel being brought before the Privy Council, because that also meant making it public. He had hoped that the adjournment would have been productive of better results, and that a committee would have been appointed to discuss the matter with the two colleges.

Dr. Pye Smith suggested that before presenting anything to the Privy Council the Council should make up its own opinion. The whole difference was the result of the Council decreeing that physics, chemistry and biology might be carried out in medical colleges and ordinary teaching institutions. The question now before them was to get a better curriculum, especially during the first year. Physics, biology, and chemistry might form a primary examination. Members of the Education Committee urged that the five years course had been maintained, but their subjects were removed to allow students to take these subjects before registration. They were not reporting a body for not keeping up to the standard he thought they ought to secure that the requirements of the General Medical Council were perfectly constant. He was, however, prepared to admit that the Royal Colleges had not treated that Council with proper consideration.

The President then moved that the report by the Examining Committee be adopted, and this was agreed to.

Notice of motion was given by Sir Victor Horsley, seconded by Dr. Bruce, that (a) "The examination in chemistry, physics, and physics of the Examining Board in England was, in the opinion of the General Medical Council, insufficient"; and (b) "The courses of study in many of the teaching institutions recognised by the Examining Board in England, but not approved by the Council, were, in the opinion of the General Medical Council, insufficient." He remarked that the Council had appointed visitors to inspect the examination, but all the comments were not, he regretted to say, before the Council. The attitude of the two bodies towards the Council was bad. There was no union. The College of Surgeons, said the report, was all that could be desired, but the College of Physicians merely said the matter would be taken into consideration. The two Colleges had taken diverse views and had placed the Council in an awkward position, and the whole affair was a scandal in medical education.

He would ask the Council to support the visitors and inspectors in saying that the examination was insufficient.

The motion (a) was carried, and after a short discussion, in which Drs. Norman Moore, Dr. Atthill and Dr. McVail took part, motion (b) was carried also.

Dr. Atthill remarked that it would be no use going into committee; the matter would have to be laid before a legal tribunal, and the Council's rights clearly defined.

Sir V. Horsley moved (seconded by Dr. B. Mackay), "That the Council do represent to His Majesty's most Honourable Privy Council that the courses of study and examination to be gone through in order to obtain qualifications for registration on the Examining Board in England of the Royal College of Physicians of London and the Royal College of Surgeons of England are not such as to secure the possession by persons obtaining such qualifications of the requisite knowledge and skill for the efficient practice of their profession."

Six o'clock having arrived, the debate was adjourned until the following day.

SECOND DAY.—THURSDAY, JULY 16TH.

Sir W. Turner, F.R.S., K.M.G., President, in the Chair.

Sir Victor Horsley, alluding to his motion of the day before, said that Dr. Windle, seconded by Sir Christopher Nixon, had given notice of an amendment to the effect that a committee be appointed to confer with representatives of all the licensing corporations with a view of some decision regarding the first year's study, and (a) the subjects in which instruction should be given; (b) places where examinations should be received; (c) examinations to be held and standard required; (d) whether any subjects now in that year could advantageously be made subjects of preliminary examinations. But Sir Victor Horsley also protested that this amendment embodied two distinct propositions, and two propositions could not be presented for one voting. The second amendment was from Dr. MacAlister to the effect that the President be requested to forward to the Presidents of the Royal College of
Physicians of London and the Royal College of Surgeons of England copies of the reports of the Education Committee and of the Examination Committee now adopted, together with the resolutions expressing the deliberate judgment of the Council thereupon; (2) that the President be further requested to call the serious attention of the Royal Colleges to the unsatisfactory state of matters in regard to the course of study and examinations in chemistry, physics, and biology which these reports disclose, and to urge that in the interest of medical education immediate steps should be taken to remedy the defects and failures of the Royal Colleges which have led thereto." If that amendment were in priority and submitted to the Council for decision, he (Sir Victor Horsley) would be very glad to vote for it, on the understanding that he had simply held over his own until November. He thought the Council should in its own interests come to an early decision, and could only do so by approaching the Privy Council; but he quite recognised that they (the General Medical Council) had no memorandum ready to forward to that body, and it would be necessary to give the Privy Council a few months to make observations on memoranda if they thought fit. It would be better to simply communicate their findings, and the Council would in all probability gain in a constitutional manner in November next, when (Sir Victor Horsley) would move his resolution founded on added information.

Dr. McKay considered the Privy Council would be justified in asking if these important facts had been communicated to the Royal Colleges. He (Dr. McKay) claimed the right as a member of a governing body of such a college that the matter should be laid before the Fellows, who were entitled to an opportunity of discussing the matter. With regard to scientific schools, he did not consider the good done in the past ten years to be commensurate with the damage done to general education. That being the case, and in view of the very guarded answer given by the College of Physicians, he was sure this last body would give the subject careful consideration.

The President remarked that he quite recognised what Sir Victor Horsley had said, and agreed that when a motion or an amendment contained two propositions the voting should be on its constituent parts.

Dr. Windle declared himself quite ready to accept Dr. MacAlister's two propositions, to add the omission, and would vote for them if proposed one by one.

Sir Victor Horsley added that if Dr. Windle withdrew his amendment he would ask Dr. MacAlister to withdraw the resolution standing in his and Dr. MacAlister's name.

Dr. McKay considered that priority in the discussion should go to Dr. MacAlister's motion, because the Council ought to show the Privy Council they were prepared to take the consequences of their act. It would be best to lay down what they (the Council) thought to be a reasonable course of instruction in schools.

The President said he understood then that Dr. Windle was to be asked to modify his amendment, and Sir Victor Horsley would postpone his motion.

Dr. Moore wished to point out that they were all trying to do their best to put an end to a state of things which the Royal Colleges had no share in bringing about. It, however, added to the difficulties of discussion when a clause, perhaps he might say a motion, was held at the Council and such a motion he (Dr. Norman Moore) considered Sir Victor Horsley's postponed motion to be.

Sir Victor Horsley interrupted that he had not asked the Parliament to enter into the difficulty. Dr. Norman Moore thought that when a resolution like that which had been made public it ought either to be carried, rejected, or entirely withdrawn because not furthering in any way the discussion. He wished Dr. MacAlister's objects,.at the College of Physicians, then he would become acquainted with the statutes and learn that the duty of the College representative was to forward the College a full report of the proceedings of the General Medical Council. A formal vote, in his (Dr. Norman Moore's) opinion, should be taken one way or the other on Sir Victor Horsley's motion.

Sir Victor Horsley intimated that he was willing to withdraw his resolution until next November.

If it was understood that Sir Victor Horsley asked leave to withdraw his motion.

The President replied that it was not quite so simple, because Sir Victor Horsley had specified a date.

Dr. Fye-Smith then spoke on the question of schools for scientific subjects, saying he was opposed them. Though some were doing admirable work, it was difficult to know where to draw the line. His opinion, however, had been shaken by the fact that a distinguished man like Sir William Gardiner had again and again spoken favourably of such schools. As to the method of examination, he (Dr. Fye-Smith) agreed with much that had been said as to its inadequacy, and would gladly believe the General Medical Council were strengthening the hands of those who were trying to make that examination more practical and useful. The subject need not necessarily lead to discord, nor the Royal Colleges be antagonistic to the "meeting." Dr. McVail had again to a constitutional manner in November next, when he (Sir Victor Horsley) would move his resolution founded on added information.

The President then asked Dr. Windle to bring on his motion, his (Dr. Windle's) amendment having been changed into such on the withdrawal of Sir Victor Horsley's motion.

Dr. Windle then read: "that the President be asked to forward reports of the Education Committee to the two Royal Colleges expressing the judgment of the Council thereon, and urging that immediate steps be taken to remedy the defects, and a further resolution was adopted authorising the President to join with him in conferring with representatives of the Royal Colleges should it appear that discussion was desirable."

Dr. Atthill remarked that there was not the slightest doubt that the first year of medical study was a failure. The majority of boys leaving school were supposed to have fifteen hours a week study, but the lectures were not every day, and the work each day was only one and a half hour, so it could hardly be expected that boys could scrape through.

Sir Victor Horsley suggested adding to the motion that the Committee should report in the following November.

Dr. Norman Moore considered it would be hardly courteous to fix a time. The Royal Colleges would undertake the amendment without appearing as if neither would the Council. The matter should be left unfettered.

Dr. Lindsay Steven regretted that Dr. Windle had withdrawn his first amendment, as in his (Dr. Lindsay Steven's) opinion it pointed clearly to a way out of the difficulty.

The motion was then carried.
Sir Victor Horsley urged that the matter in hand should not be discussed at the cost of the profession any longer, but it would be unless brought to a close in November.

Mr. Bryant then read the report by the Examination Committee on the report by the visitors of the examinations in chemistry, physics and biology of the Apothecaries Society of London. There was, it seemed, in biology, no paper and no practical test, the examination being wholly oral. In physics there was both written and oral work. In chemistry the practical examination did not include the preparation and exhibition of specimens of compounds. This was to be amended, and the visitors neither reported the standard to be too low nor regarded the examination as a sufficient test for medical students at the end of their first year. The Committee agreed with the visitors that the average training of candidates was insufficient for men commencing medical studies.

The report was then adopted, being moved by Mr. Bryant and seconded by Mr. Young.

Sir Hugh Beevor said that he neither opposed nor supported the motion. With regard to the question of training, suggestions made by visitors were perhaps not so clear as they might be, nor should the visitor be asked to pronounce on questions of study. This report ought to receive more than ordinary attention.

The motion having been adopted, Dr. McVail remarked that the finding was that the training in physics given was "of no value in after life," that the training furnished to the students was insufficient. Whether the position of the Council if the council acting for the Royal Colleges before the Privy Council should show that the General Medical Council, with regard to a report similar in character, had contented itself with simply calling the attention of the Apothecaries to the matter. He (Dr. McVail) then moved "That in the opinion of the General Medical Council the examination in chemistry, physics and biology of the Apothecaries Society in London was insufficient."

Sir Victor Horsley said it should be borne in mind that the Apothecaries Society had accepted the report of their visitor, whereas the College of Surgeons had not accepted it, and the College of Physicians was only considering it.

The motion for adopting the report, proposed by Dr. McVail and seconded by Dr. Bruce, was carried.

After long discussion, consideration of the Report was postponed; the President being asked to arrange for another inspection of the University of Oxford during the ensuing year, the Report to be considered by the Council before deciding as to efficiency of examination. The Council then retired in camera to receive a report from the Office Site Committee.

BRITISH SANATORIA FOR CONSUMPTION.—IV.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

THE CONSUMPTION SANATORIA OF SCOTLAND—BRIDGE-OF-WIEH.

The Orphan Homes of Scotland, established through the philanthropic labors of Mr. William Quarrier and his many willing helpers, at Bridge-Of-Weir, in Renfrewshire, are deservedly famous throughout the world. A natural extension of the work of this excellent institution has led to the building of two admirably-constructed pavilions for consumptives, each affording accommodation for forty patients. The pavilions face south, are built of red sandstone and brick, with stone stairs and floors of pine. Nearly all the rooms face south, the corridors run east and west, and the dining-hall is situated on the north side of one of the buildings. The rooms are not heated, but in the winter the corridors and dining-hall are warmed by means of steam radiators. Although the site cannot be considered perfectly ideal, the sanatoria are well designed, excellently equipped and ably managed. Since the sanatoria were opened, 540 female patients have been in residence, and 2,335 cases have received advice and treatment at the dispensary in Glasgow connected with the institution. The present accommodation of eighty beds is proving altogether inadequate for the immense demands, and large numbers of cases are always awaiting admission. £6,000 is required annually for the maintenance of the present sanatoria, and £10,000 are needed for three additional sanatoria for women, and £70,000 for five sanatoria for men. As far as we can gather, the management is economical, and yet wisely so, for it is stated that 30s. a week is the cost of each patient. Hitherto admission of necessitous cases has been free, but recently a small payment is required, although the right to admit free cases is retained. The last medical report shows that during the year 230 patients were discharged, and the average period of residence was approximately four months. We do not altogether approve of the manner in which the statistical results are expressed. To return 167 per cent. as "cured," and 279 per cent. as "relatively cured," seems open to serious objection, although the words used are defined: "under 'cured' are placed those patients in whom we regard healing to have taken place with the formation of cicatricial tissue, and 'relatively cured' is applied to those patients who are practically well, and physically fit to return to suitable employment and earn their livelihood."

The sanatoria are under the direction of a resident physician, Dr. H. Hyslop Thomson, who acts under an advisory Board, of which Dr. T. M'Call Anderson is Chairman. The hygienic management of the consumptive patients is thoroughly controlled and much attention is devoted to dietetic arrangements. Koch's tuberculin is occasionally used for diagnostic purposes. Careful scientific records are kept, and the clinical work is thoroughly carried on.

The sanatoria are well equipped with steam dynamo, boiler room, laboratory, and other necessary offices. The cost for building is said to have been about £250 per bed, and about £50,000 have been spent on the estate.

The sanatoria are easily reached by trains, which run every hour, from St. Enoch's Station, Glasgow. From Bridge-Of-Weir Station to the sanatoria is a mile and a half, but arrangements are made whereby a carriage will meet any train. These pavilions admirably illustrate the manner in which provision may be supplied for the consumptive poor, and indicate also the wisdom and enterprise of an institution with other forms of philanthropic enterprise.

An Extraordinary Case of Swallowing Foreign Bodies.

A very curious case of gastric tolerance was told by M. Monnies at the last meeting of the Académie de Médecine. In May last a young country boy, aged about 18, and of a very limited intelligence, entered the hospital complaining of great pain in the epigastrum. Examined, nothing very definite could be found as to the cause of his suffering, and milk diet was ordered. However, fifteen days afterwards the house surgeon thought he perceived by palpation a foreign body in the stomach. He drew the attention of his chief to his suspicions. After a careful examination, M. Monnies could distinctly feel an elongated body lying across the large curvature of the stomach. It was decided upon, and when the organ was opened two teaspooons were easily extracted quite
black. Passing his finger into the incision, he discovered a hard metallic mass in a pouch perpendicular to the large curve. From here he extracted successively six more teaspoons, a piece of a fork with three prongs, the handle of that fork broken, another handle of a fork, a very long nail, a shorter nail, a needle, the handle of a knife, a small knife blade, a small key, a tooth of a comb, and some broken pieces of iron, in all twenty-five articles, all of which Monnies presented to his colleagues. The patient made an excellent recovery. Being asked why he had swallowed these foreign bodies, the boy declared that he was rendered very unhappy, and, persecuted by his stepmother, he tried to put an end to his life by swallowing the teaspoons, &c.

M. Monnies passed in review the history of similar cases, and rightly concluded that his patient had beaten by long odds the record, not only as to the number of articles ingested, but as to the extraordinary tolerance of the stomach, for the patient must have possessed a regular ostrich's stomach to have tolerated the presence of so many sharp-pointed objects, which in others would not have failed to provoke perforation or ulceration of the organ.

Purulent Pleurisy.

M. Léjars read a paper before the Société de Chirurgie on two cases of chronic purulent pleurisy treated by partial resection according to the method of Schede, followed by decortication of the lung, as recommended by Delorme. The first operation was incomplete, and the speaker had to return three successive times at several weeks' distance. Finally the patient recovered without a fistula. In the second case, after two operations the result was equally satisfactory. M. Léjars said that in several cases he had to adopt this plan of successive operations.

M. Tuffier declared that he had completely renounced large operations in one sitting; he was a strong partisan of repeated interventions.

M. Ferrier treated an identical case as above mentioned. It was that of tuberculous purulent pleurisy. After a first costal resection improvement took place in the condition of the patient; he resected other ribs, and the suppuration diminished. After five or six operations he had to stop at the second rib, behind which was a vomica. The patient returned to his home, and from latest news he was very well.

Cerebral Arterio-sclerosis.

A patient of about fifty years of age has hard and rigid pulse, complains of vertigo, often accompanied with epileptiform seizures. The urine contains traces of albumin, or perhaps none. What should be the treatment?

Professor Huchard, who is an authority on all therapeutical questions, recommends as follows:—

First a lacto-vegetarian régime, with one or two days weekly of exclusive milk diet. Blisters are employed by a number of practitioners, but as a certain amount of kidney lesion exists, congestion of these organs might be provoked. Professor Huchard prefers the old-fashioned seton in the neck; it is much more certain in its effect, and causes but little trouble after the first few days. As intestinal revulsives drastics were indicated:—

Sca mmonde,
Jalap.

in two powders, to be taken at twenty minutes' interval and repeated every ten or fifteen days.

In the interval and fasting a wineglass of some mineral water (purgative) every morning, or the following pill at night:—

Aloes, 1 gr.
Ethonylvine, 1 gr.
Pedophyllin, 1-5 gr.
Ext. of hyoscyamus, 1-10 gr.
Ext. of belladonna, 1-10 gr.
Twenty days a month the patient will take before dinner and supper a tablespoonful of

Iodide of potassium, 3j.
Water, 3x.
The remaining ten days theobromine as a diuretic and eliminator of toxins:
Theobromine, x grs.
Benzoate of soda, v grs.
Carbonate of lithine, iij grs.
For one wafer; two daily.
If the theobromine is badly tolerated (pains in the head, gastric disturbance), one of the following powders will be substituted:

Nitr. of potash, xv grs.
Bicarb. of soda, x grs.
Bicarb. of potash, x grs.
to be taken in a diuretic infusion, or, more simply, in Evian water.

In case of epileptiform seizures, bromide of potassium will be associated with the iodide:—

Iodide of potassium, 3j.
Bromide of potassium, 3j.
Water, 3x.

Two tablespoonfuls daily.

Germany.

[FROM OUR OWN CORRESPONDENT.]

[BRUSSELS, June 18th, 1903.

An article by the Society für innere Medizin, Hr. Herbner brought forward a

Case of General Infection with Thrush. Only few such cases had been published, and besides this the case was one of great clinical interest. It was the first case in which such general infection had been diagnosed during life. The case was that of a weakly child, aged 15 months, the weak condition being due to improper nourishment rather than to any particular illness. The body weight was only one-half of the normal. Four weeks before the death of the child a general illness came on, characterised by great paleness and loss of appetite. A diagnosis of diphtheria had been made before the child's admission, and it was placed in the diphtheria ward. After admission, however, this diagnosis was not confirmed. There was no proper membrane and no swallowing of glands. Neither was there any diphtheria streptococcus; both streptococci and staphylococci were present in the deposit, but not in almost a pure culture as in scarlatina, but mixed with other micro-organisms. The fever was very high. Locally there was nothing special. The cry was loud, a good deal of dyspnoea, whilst there was no disease in the lungs, and the larynx was free. The temperature was at 41° C., frequent pulse, restlessness, and jaundice. The local condition was peculiar. The situation of the disease on the tonsils was quite different from what it usually happens in diphtheria. The deposit was not pasty, but dry, almost crumbly; it could not be broken off, however, but stuck fast. The symptoms as a whole led to the thought that they might be due to general infection with thrush. On examination of the deposit aphthae cells and threads were found in it; but only in the tonsillar deposit. On demonstrating the child to the class, the speaker said the case was not quite clear, but possibly there was
passage of aphthous cells into the circulation. After death the necropsy revealed nothing. No aphthous cells were seen on the tonsils, both larynx and lungs were free. Some sections were, however, taken from the tonsils and the kidneys for further examination. The tonsils, with the generalized necrosis, were almost the whole tonsillar mass—an inflammatory haemorrhagic necrosis. Besides this, there were larger cells of aphthous character in large masses, not only in the necrosed masses, but also in the lymph vessels there were small sproutings of vegetable cells. In the kidney preparation also there were these sprouting bundles, not only swimming in the vessels, but also particularly glomeruli. In cultures of scraped off material from the tonsils some cultures of plant cells developed. In bouillon the cells developed in a marked manner as aphthae. Animal experiments were made, and the cultures proved highly pathogenic. A quarter of a syringeful was injected into rabbits. For two days they remained lively, jumped about and ate. On the third day, however, an illness like that of the children developed with high fever, dyspnoea, gradual paralysis of all the limbs; the animals cried out and groaned as if in great pain. The animals most infected died on the fifth day; one died on the seventh. The blood serum of the dead rabbits did not seem to be poisonous to other animals. Examination showed all the organs to have accumulation of aphthae that looked to the naked eye like miliary tubercle, but particularly in the kidneys and heart. Professor Reinhardt, of the Botanical Institute, declared the organisms to be identical with aphthae. It was certain that the general infection had been caused by the thrush, as nothing else was found in the kidneys.

The thrush infection had taken the same route as streptococcous infection in scarlatina. The localisation of the poison cells in a few places on the fauces and tonsils, while the tongue and mucous membrane of the tonsils were quite free, was not usually the case in thrush. The lungs were free also in the rabbits. They were present, however, in the kidneys, the heart, brain, spinal cord, the liver and spleen, but less numerous in the latter. There was no inflammatory reaction in the different organs. Death was not due to paralytic symptoms, but to a mechanical cause. Possibly a poison had developed out of the cells, but it had not caused the death. There were no military nodules in the kidney, as in the cases of the rabbits, possibly on the reason that the onset of the disease had been a destructive one. The cortical substance of the kidneys showed an enormous general infiltration of vegetable cells.

Hr. Kraus remarked that three or four cases of the disease had been observed, as, for instance, by Zenker and Ritter, where a cerebral abscess developed in which the fungus was found. In Schmori's case there were abscesses in the kidneys and spleen. Then there was an Italian case, but there was some uncertainty about it. On personal examination of the microscopy preparations it had struck him that nowhere there was any reaction from the thrush fungus. Stenier had described a similar case of general infection, but he found everywhere a small-celled infiltration.

Hr. Klemeren, who had made experiments on the subject said that generalised thrush had a merely mechanical action, never a poisonous one. It was not possible to prepare a poison from it.

Hr. Heubner said that the absence of inflammatory reaction and abscess was possibly due to the rapid development of the disease, that caused death before inflammatory reaction had time to be set up. Concetto had said that thrush could develop a very active poison.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, July 15th, 1903.

THEOCIN IN STENOCARDIA.

Pinskiés brought forward three cases in the Gesellschaft für innere Medizin, which he has treated successfully with theocin.

This substance contains from one to three parts of dimethylxanthin, and relieves cardiac pain as well as the stenosis, and he considers it to be far superior to diuretin. Theocin is a cheap and harmless drug with no bad effects on the stomach. It has a stimulating action on the nervous system of the neuropathic resembling caffeen or trimethylxanthin. It is usually administered in doses of 0·2 grammes, or about 3 grammes, after breakfast, which may be repeated with advantage in cases of angiosclerosis. Many patients hear 0·3 gramme of the drug with perfect ease. The three patients were now 3, 4 and 5 months respectively perfectly free from pain or discomfort after treatment with the drug. After a short course of theocin the blood pressure is reduced, while the diuresis remained unchanged and without any recurrence of the pain.

Teleky found that in daily doses of 0·6 to 1·0 grammes in cases of arterio-sclerosis with anasarca, theocin was much more efficacious than diuretin. He found by experiment that the ingestion of from 3 to 3·5 grammes of diuretin was followed by an elimination of 500 c.c. to 700 c.c. of urine, while theocin gave 1,300 c.c. Theocin was therefore anti-asthmatic, as well as anti-sclerotic, and the results were uniform, whilst diuretin was unreliable, as he showed patients intoxicated with sclerotic vessels, in whom it failed completely. This patient was relieved by the use of theocin.

Nothnagel said he had used diuretin for the last five years with varying success. He quite agreed with Teleky that it failed in many cases. As far as he had used theocin he was bound to speak in its favour as an anti-asthmatic and sedative remedy.

Pinskiés thought that Teleky's observations related more to arterio-sclerosis and cardiac insufficiency, the latter being the most prominent symptom, which was favourably acted on by digitalis; but where stenocardia was present the resulting disadvantages were great.

Pauli confirmed the antagonistic results of diuretin and digitalis. In cases of pure stenocardia, where diuretin is well borne, the asthma and cardiac symptoms are efficaciously relieved, but cardiac insufficiency is not to be relieved by any of the theobromate preparations, such as theocin, &c.

Reitter remarked that in Schröter's Klinitdiuretin was extensively used, and with excellent results, more particularly in stenocardia.

BILIRUBIN IN URINE.

Jolles reported a modification of his test for bile colouring matter in urine which he brought before the meeting three years ago. Briefly stated, 10 c.c. of urine are placed in a test-tube with 2 or 3 c.c. of chloroform and 1 c.c. of a 10 per cent. solution of chloride of barium, and well shaken. The whole is put into the centrifuge; the supernatant fluid is then poured off, leaving the chloroform and deposit, to which is added distilled water, shaken, and again centrifuged, and the supernatant fluid decanted. The chloroform and deposit are next treated with 5 c.c. of alcohol, well shaken and filtered. To the filtrate is now added two or three drops of the iodine solution, e.g., iodine 0·5 grammes, mercuric chlor. 0·7 grammes, dissolved in alcohol 125·00 grammes, i.e., the iodine and mercuric chlorid
in 125 cubic centimetres each. Mix these and add 250 c.c. of concentrated HCl, which should now be kept in a dark brown bottle for immediate use.

The slightest trace of bile pigment present in the prepared alcoholic chloroform solution will be detected by a green coloration after adding two or three drops of this solution. It may be a little slow in forming, but the coloration can be hastened by placing the test-tube in a water-bath for a few minutes.

When the urine is very concentrated and a rapid result is required, 5 c.c. of alcohol may be added to the urine and centrifugated, returned to a test-tube and treated with 2 drops of the iodine solution, warmed and then filtered. A trace of bile matter will give a greenish-blue coloration to the filtrate. The reaction is not influenced by the presence of either indican, urobilin or haemoglobin, or methaemoglobin. The quantitative test may be carried out by comparing an artificial urine containing 0·1 of a milligramme per cent. of bilirubin.

SUPERPHRENIC ABSCES.

Nothnagel demonstrated from an anatomical preparation the pathological history of a case of suprarenal abscess. The patient was a 25-year-old man who first complained of acute angina and occasional haemoptysis. During this period there was intermittent fever and rigors. In the lungs there were symptoms of haemorrhagic infarcts, in the sputum streptococci, with constant symptoms of mitral insufficiency. All the signs of phthisis were absent. The endocarditis followed by angina and pulmonary infarct and terminating in a suprarenal abscess. The patient died suddenly from collapse.

The post-mortem examination revealed traces of endocarditis, multiple pulmonary infarcts, and an encapsulated abscess between the diaphragm and base of the right lung, with which it communicated.

In the light of the post-mortem results we must assume that the angina arose from the small abscess near the base of the right lung, which at a later date formed the suprarenal abscess from which the emboli were carried by the vena azygos, vena cava, and through the heart into the lung. The insufficiency of the mitral valve was not due to any morbid condition of the valve or valvular affection, but rather to a functional or fatty degeneration of the myocardium, which might be due either to bicuspid ostium dilatation or functional insufficiency of the papillary muscles.

Hungary.

[FROM OUR OWN CORRESPONDENT.]

Budapest, July 17th, 1903.

At the recent meeting of the Budapest Royal Medical Society Dr. Leimart related a case of PRIMARY NASAL CANCER.

Cancer of the nose is of very uncommon occurrence. In literature on the subject we find altogether some eighty cases described. The growth was usually preceded by catarrh or affections of the accessory sinuses, sometimes after damage by harmful chemical vapours, trauma, &c., but these influences cannot play a very important part in the etiology, because the symptoms are common to all nasal affections. As to the as yet unsolved problem whether benign polyps can be transformed into a carcinoma, the author quotes a case of his own where a cancer of multiple origin had its origin in the basal cell-layer covering the polypus, which became infiltrated with cancerous growth.

The earliest symptom of nasal cancer is persistent unilateral obstruction, and this is also the most frequent symptom, because the nasal bleeding, the discharge from the nostrils, the neuralgic pains, &c., either occur later or may be altogether wanting. In view of the site of the swelling in the recorded cases it appears that in half the cases the growth originates in the region of the middle turbinal, and only in exceptional cases from the inferior turbinal, the septum, the nasal roof, the cavity of Highmore, or the sphenoidal sinus. Later, the symptoms of the disease are—deformity of the nose due to the gradual increase in size of the swelling, pains, throat and ear affections, invasions of the orbit, and cerebral symptoms due to pressure on the brain. Metastasis was only observed in one case.

A cancerous tumour of the nose is easily distinguishable from the benign tumours of that organ; but to discriminate cancer from sarcoma we must rely on histological examinations. The treatment of cancer of the nose is necessarily surgical. In the initial stage, when the swelling is circumscribed, a radical operation is to be resorted to, and only in the later stage, when the disease can no longer be extirpated, are we justified in considering less radical and more conservative methods which may be indicated for the relief of the most troublesome symptoms. The prognosis is very grave, in fact, up to the present there are only two cases of recovery on record.

Dr. Fleischmann read a paper on BACTERIOLOGICAL EXAMINATIONS IN OTOLARYNGOLOGICAL PRACTICE.

The author has made an extensive series of examinations in the clinic of Professor Böke. The subjects of examination were five cases of independently occurring middle ear catarrh. Examining the blood and purulent discharge obtained by paracentesis he found therein red and white blood corpuscles with healthy and decomposed tissue elements. By inoculation in all the five cases pure cultures were obtained—namely, in one case pure staphylococcus albus; in two cases staphylococcus aureus; in one case the streptococcus, and in the last instance strepto- and staphylococci mixed. This state of things coincides with that found by Zoufal, who, in addition to the above-mentioned organisms, also recognised Faenkel diplococci as an etiological factor in producing middle ear catarrh. The author opposes the conclusions of Lermoyer and Helme, who hold that the staphylococcal infections were mostly mixed ones, while he himself only found one among four of such a kind. It is, therefore, clear that in acute myringitis pus-producing germs are present even in the hyperaemic stage, a fact which justifies the performance of paracentesis practised on the ground of clinical experiences. Thereby we arrest the inflammation, which is favourable to the propagation of the germs, and would finally lead to middle ear suppuration.

The author cannot as yet draw any conclusions from his examination of the germs existing in chronic middle ear catarrh. However, he mentions a case wherein middle ear catarrh was accompanied by caries of the petrous bone, and in the discharge pouring therefrom he found abundance of tubercle bacilli. In another case pure culture of the bacillus pyocyaneus was obtained from the pus.

The UNIVERSITY OF BUDAPEST.

This institution keeps pace with the Western universities. Recently, valuable prizes were offered for researches on the following subjects:—

Physiology.—To be examined: the quantity of the organic constituents of the saliva with special reference to the different circumstances of life in respect of alimentation, the quality and quantity of foods, rest,
and work, and the different periods of the day. Prize, 520 crowns.

General Pathology and Therapeutics.—Experiments to be made as to the nervous mechanism of giddiness due to labyrinthian disease. Prize, 170 crowns.

Morbid Histology.—(1) On the development of the Botalli duct and umbilical vessels. Prize, 120 crowns. (2) The structure of lymphosarcomas occurring in the digestive tract. Prize, 130 crowns. (3) The comparative value based on actual observation of the value of various new culture media for the diphtheria bacillus and gonococci, with special reference to rapidity and trustworthiness of the cultivation. Prize, 140 crowns.

Clinical Medicine.—The value of percussion-auscultation as contrasted with the methods hitherto applied. Prize, 520 crowns.

Surgery.—The value and results of the orthopedic surgical treatment of tuberculous arthritis. Prize, 140 crowns.

Obstetrics.—(1) Clinical and histological study of the changes in the tissue structure of the uterus, which predispose to uterine rupture. Prize, 140 crowns. (2) The etiological factors of puerperal diseases on clinical and bacteriological basis. Prize, 320 crowns.

Public Hygiene.—(1) Whether muscle, flesh, and other animal tissues which are used as foods can be substituted for each other according to their nitrogen contents, or in some other proportion. (2) The action of some of the more important mineral and organic disinfectants upon granulating surfaces, upon fungi and schisomyces, and upon certain enzymes, and whether the disinfectants in question form compounds with the protoplasm of the micro-organism or with their sheaths respectively with the enzymes. Prize, 170 crowns.

Dermatology.—To be discussed on ground of independent histological examination, the alterations which the human skin undergoes in acute and chronic eczema.

Medical Jurisprudence.—The statistics of inquests held between the years 1882-1901. Conclusions to be drawn as to the most frequent causes of suicide, especially bearing in mind those causes which are the various organic diseases of the subjects. Prize, 520 crowns.

The Operating Theatres.

ST. THOMAS'S HOSPITAL.

Removal of the Appendix.—Mr. Battle operated on a man, æt. 35, a soldier, who had been sent to the hospital for removal of the appendix. He had had three attacks of appendicitis, of which two had been very severe. He was desirous of himself of the operation. There was nothing to be found in the abdomen on external examination, and the temperature was normal. Mr. Battle operated by the method that bears his name; an oblique incision was made through the skin and subcutaneous tissue, midway between the anterior superior spine and the umbilicus; the inner side of the wound was then retracted towards the umbilicus and the anterior layer of the sheath of the rectus divided to the full length of the wound (about four inches); the rectus muscle was then separated from its sheath and drawn inwards; the posterior layer of the sheath and peritoneum were now divided about an inch to the inner side of the margin of the sheath; the finger was introduced through the opening thus made and an exploration of the caecal region made with the finger; some adhesions were found, but the appendix could not be felt; there was, however, an unusual induration where the caput cecii came towards the iliac fossa; the deeper part of the wound was enlarged to its full extent, the appendix region isolated by means of gauze strips, and a search made for the appendix, of which there was no indication excepting the thickening mentioned. A longitudinal band was followed towards the appendix region, and where it was lost to sight a director was used to separate the overlying adhesions and peritoneum. About an inch from the commencement of this wound the appendix, one of the appendix was evident, well indicated, but it was immovably fixed in the indurated part under the caecum; this was very difficult to separate, and it was only by careful use of the knife that it was possible to get the distal end up. The adhesions were extremely hard, and the appendix bound down as if set in cement. The appendix was clamped with a special clamp and removed, but great difficulty was experienced in arresting the bleeding from a moderately sized artery of the meso-appendix which had been torn in separating the appendix from its bed; it was fixed in such dense material that forceps simply cut through it as if it were cartilage; it was only by taking a large piece of tissue that it was possible to secure it. No suppuration was found, but there were some large-sized spots of pus. He suggested that pus had been present at least during one of the attacks. The stump of the appendix was sutured into the wall of the caecum by interrupted Lembert sutures, and the area of operation again made retco-peritoneal by means of similar sutures applied on both sides of the incision over the region around the caecum. The peritoneum closed, the strips of gauze removed, and the wound closed by means of buried silk sutures, a horse-hair stitch being employed for the superficial part of the incision. The operation was carried out aseptically, the operator and assistants wearing sterilised gloves, as is usual in Mr. Battle's operations. Sterilised dressings were employed for the wound. Mr. Battle said that the case was an example of what he now well knew that the number and apparent severity of attacks of appendicitis are no criterion as to the condition which the appendix will present when operation takes place. Here the patient had had about three attacks of moderate severity, and the appendix was so imbedded in inflammatory tissue and adhesions that it was necessary to use a knife in order to free it, whilst it was concealed altogether from view. In another case recently in the wards, he said, the patient had had two or three attacks of moderate severity during the course of two years and about a hundred attacks of pain in the appendix region, and yet the appendix was free, not much enlarged, and presented only signs of a subacute inflammation. The difficulty in finding the appendix may be so great, he pointed out, that surgeons of some experience have failed to discover it and have been obliged to abandon the search for it after perhaps more than one operation undertaken for its removal. The appendix in the present case, he remarked, was about four inches long, and presented the usual changes following chronic inflammation; there was no concretion, nor was there any stricture present. To draw attention to the use of a clamp in the amputation of the appendix, as he considers it the quickest and most satisfactory method in use. The appendix having been freed, and its mesentery secured with artery forceps, the clamp is applied at the junction of the appendix with the caecum, the meso-appendix is ligatured and divided, after which the clamp is removed and a fine silk suture used to tie a part which has been compressed; thus an extremely small strand of tissue is left to be sewn into the caecum.
THE MEDICAL PRESS AND CIRCULAR.

The Medical Press and Circular.

Published every Wednesday morning, Price 6d. Post free, 8d.

ADVERTISEMENTS.

For Our Insertion—Whole Page, 45 6d. 6s.; Half Page 23 10s. 6d.; Quarter Page, 6 5s.; One-eighth, 12 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the Publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thick plate paper for foreign and colonial subscribers at 6s. per annum, post free, if paid in advance, or 8s. 6d. credit rate.

Small announcements of Practices, Assistantships, Vacancies, Books &c.—Seven lines or under (70 words), 6s. 6d. per insertion, 6d. per line beyond.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 22, 1903.

THE GENERAL MEDICAL COUNCIL AND THE ENGLISH CONJONT BOARD.

The long-standing dispute between the General Medical Council, as the supreme authority in matters concerning the education of medical students, and the English Conjoint Board has been advanced a stage at the special meeting of the Council which took place last week in that it has brought matters to a crisis. After long but, on the whole, temperate discussion, the Council has decided to refer the matter back once more to the colleges before taking the ultimate step of appealing to the Privy Council. Since the legal position of the Council in this matter is not clear even to the members thereof, we may be excused if we decline any special competence in the matter, our feeling being that if the Council do not in reality possess the powers which are claimed for it, the sooner the fact is established the better. We shall then know how we stand, and although an adverse decision might be productive of some amount of confusion and even humiliation, it would tend in the long run to place the authority of the Council in matters educational on a sounder basis.

An interesting feature which results from the discussion is that the two partners in the Conjoint Board are not agreed on the merits of the question. We may even go so far as to admit that the attitude of the College of Surgeons on this, as in respect of sundry other questions, has been characterised by a moderation and sense of propriety which is sometimes wanting in that of the more autocratic College of Physicians. The recalcitrancy of the College of Physicians is the more surprising and regrettable in view of the remarkable statements of inspectors of examinations; The visitor and inspector, for instance, expressed in their Reports their opinion that the syllabus is extraordinarily defective, alike in matter and arrangement," while from observation of the candidates he is driven to the conclusion that "the candidates were so badly prepared that a higher standard than the one imposed would have led to the rejection of the majority." The Board's comment on this drastic phraseology is that "the present mode of conducting the examination is the most suited to the circumstances." In other words, we may infer that the ignorance of the candidates in respect of the subjects of examination is such that to seek to impose a higher standard would eliminate too large a proportion of the candidates. This is at any rate the construction placed upon the correspondence by Sir Victor Horsley. It is hardly to be supposed that the importance of a preliminary education in the elements of physical science can give rise to any serious difference of opinion between the Conjoint Board and the Council, nor can the question of the standard to be imposed give rise to much difficulty, yet we are confronted with the spectacle of a persistent revolt on the part of the Colleges against the beneficent authority of the Council which, unless modified, will leave the latter no alternative save to seek to vindicate its position before the Privy Council. Looking at the matter from a higher standpoint, the circumstances would certainly seem to reflect discreditably on the state of education in this country. When we consider the unexceptionable authority that the general standard of scientific education among young men destined to become members of a learned profession is so low that the examiners are fain to accommodate their requirements to the ignorance of the examinees, it becomes manifest that wide-reaching reform in educational methods is urgently required. Technical education in other sections of the community is advancing by leaps and bounds, at any rate in regard to the facilities for imparting instruction, but in our public schools little has apparently been done to improve on the old routine.

OPHTHALMIA NEONATORUM.

The prevention of blindness, to however small an extent, clearly represents an important economic gain to the community, apart from its desirability on humane grounds. It so happens that a fruitful cause of blindness, ophthalmia neonatorum, has been given into the hands of modern science as an absolutely preventable disease. Competent authorities have estimated that purulent ophthalmia of newly-born children is answerable for upwards of ten per cent. of the total blindness in the United Kingdom. The cause of the malady is infection by one or more pus-producing micro-organisms, among which are pneumococci, Morax's diplobacilli, bacteria coli, and various cocci. The gonococcus, however, is by far the most common and serious form of infection. This important subject was discussed by the Obstetrical Society of London at a meeting held on July 1st. It was introduced by Mr. Sydney Stephenson, who, in addition to a wide general experience of eye diseases in chil dren
has found a special field of study as regards ophthalmia neonatorum in his capacity of Ophthalmic Surgeon to the Queen Charlotte's Lying-In Hospital. He pointed out that a baby's eyes might become infected with gonococci either in the maternal passages or immediately after or within a day or two of birth. His contention, which appears to be established beyond the shadow of a doubt, is that the whole sum of suffering and disability inflicted by ophthalmia neonatorum might be absolutely prevented by the use of a few simple precautions. The method advocated by Mr. Stephenson was the original one of Crédé, which depends on the routine treatment of the eyes of all newly-born infants with a solution of nitrate of silver. Other drugs were, in his opinion, inferior to that particular salt. The only disadvantage he admitted was the almost constant production of a slight conjunctival catarrh. That objection, however, was emphasised by members of the Obstetrical Society, who made the pertinent remark that an inflammation of a baby's eyes was not a trifling thing from the mother's point of view. One speaker said he had strongly advocated the legislative control of midwives, and had found his most telling argument in the preventability of this form of blindness. The strength of his position, however, was later honeycombed by the admission that he did not know whether the Midwives' Board intended to enforce any action with regard to the disinfection of the eyes of the newly-born. Nor did he approve, apparently, of a mid-wife carrying more than one kind of antiseptic, so that nitrate of silver could not be included in her already overloaded bag. Another leading obstetrician said he could not recall an instance in which he had received any clue to the diagnosis of gonorrhoea from the Bacteriological Department of Guy's Hospital. To make a public statement of that kind is surely to cast a serious and, we doubt not, unmerited slur upon the efficiency of the scientific staff of a great London Hospital. If gonoccal pus is now within the reach of any well-educated and well-equipped advanced student or medical man. On the whole, it seems that the Obstetrical Society, in approaching this subject, have hardly risen to the importance of the discussion. What would be thought of any learned medical society that belittled the importance, say, of the bacteriological diagnosis of throat secretions, or of pleuritic effusions, or of spats? Yet the Obstetrical Society has failed to express any strong convictions either for or against a plan of prophylaxis whereby the sight of many children would be indubitably saved. Under present circumstances a plain verdict from an authoritative body would have had considerable value as an indication of light and leading. Non-committal counsel in so essential a matter simply amounts to a confession of weakness. The Crédé prophylaxis of ophthalmia neonatorum is either right or wrong. As Mr. Stephenson pointed out, no single instance was brought forward to show that bad results had followed the application of that method. Whatever the present attitude of learned societies may be with regard to this question, there can be, happily, no doubt as to the view that will be adopted by the coming scientific generation, with whom the old proverb, "Prevention is better than cure," will have acquired the weight of established and authoritative law.

THE PHYSIQUE OF URBAN POPULATIONS.

The three speeches in the Upper House on July 6th of the Earl of Meath, the Bishop of Ripon, and the Duke of Devonshire, respectively, struck a very important note with regard to the actual or supposed degeneration in the national physique, especially in that of the large cities. The report of the Royal Commission on Physical Training in Scotland distinctly states that there is "an undeniable degeneration" in certain classes. It is not pleasant to be informed that physical inferiority is more marked among the poor than the rich, a state of affairs which can be readily understood, owing to wide differences in feeding and environment, but which should certainly not be allowed to continue without the strongest efforts being made to overcome the disparagement between the two classes. The learned prelate, though willing to admit that there had been an improvement in the direction of stature and mean longevity, alluded to the influence of restriction of population by artificial means as an important factor in the causation of the diminishing birth-rate, and held that the increasing luxury of modern times tended towards national degeneration. This is certainly true in regard to urban populations where time-saving appliances and conveniences conduce to lessened output of physical energy and exercise. The returns of the Inspector-General of Recruiting, although by no means conclusive in themselves, serve to show that there is a steady increase in the number of recruits rejected on grounds of physical insufficiency. Considering that most of these are drawn from the working classes, and that these inhabit the great urban districts, it is impossible to arrive at any other conclusion than that the physique of the urban populations is deteriorating. The fact, stated by the Director-General of the Army Medical Service in a minute brought before the Secretary for State for War, that one out of every three men examined by the medical officer of the recruiting department is rejected is sufficient to call for the most careful consideration of those who have the true welfare of the nation at heart. As has been pointed out, a large number of men are rejected by the recruiting sergeants themselves without ever being medically inspected, so that there is an even greater proportion of physically unfit than appears at first sight. From the social and economic standpoint, this is a serious matter, for it means that a considerable number of men employed in various civil duties are of inferior physique. There is no reason for supposing that the physical conditions of Scotchmen are in any way different from those of other countries of Great Britain, and it is to be earnestly hoped that the report of
the Scottish Commission will stimulate the Government to form a Royal Commission to investigate the whole subject of physical deterioration, a suggestion put forward in The Medical Press and Circular for June 24th, 1903. It is a matter for great satisfaction that it is proposed by the Legislature to consult the Royal Colleges of Physicians and Surgeons, through their respective Councils, as to the best means of obtaining trustworthy information regarding the question of physical deficiency. It is the causes of this deterioration and the methods of its prevention which will, no doubt, occupy the most prominent place in the proposed investigations, and these preliminaries completed, the data furnished thereby should provide ample material for the consideration of a Royal Commission. The subject is admittedly a very wide one, including as it does questions of public and private hygiene, education and factory laws among other topics, but it is only by determined and persistent efforts to rectify shortcomings bit by bit that at last a revival of the whole for the better can be ultimately attained.

Notes on Current Topics.

The Bloodless Operation of Lorenz.

The introduction of the Röntgen apparatus as an aid to diagnosis has demonstrated that congenital dislocation of both hip-joints is a more common pathological condition than the older surgeons imagined. For the deformity very little was done until Professor Lorenz introduced his bloodless operation. The operation has proved so useful and so safe that it has become generally adopted, and with almost uniformly good results. This success of the operation, is, however, a source of danger; it makes surgeons less careful in the selection of their cases and more apt to run greater risks than they should. The unfortunate thing in the selection of a case for the Lorenz operation is that there are unsuitable cases that cannot be diagnosed as such, no matter what care is taken, cases in which the X-rays fail to detect the condition that makes success impossible. We refer to anatomical abnormalities of the capsules and round ligaments. In a case on which Professor Wilson, Philadelphia, operated this year the round ligament was found to be 5½ cm. long, 0.4 cm. wide, and 0.2 cm. thick at its middle, expanding at both ends. The acetabular insertion was so expanded that it occupied all the interior third of the cavity. The capsular ligament was thick and loose, and slipped between the head of the bone and the acetabulum. The attempts to effect reduction failed, and after an hour and a half's trial the child was removed to its cot, where it died, after thirty hours' illness, from pneumonia and acute nephritis, resulting from etherisation. In this case the greatest trouble was taken to guard against failure. Skagrams were taken, and the hip was freely manipulated to detect any abnormalities other than the congenital dislocation. That it was examined with the skill begotten of experience is proven by the fact that it was the only unsuccessful case of twenty-three cases operated on. We are not aware of any diagnostic sign that would detect the undue encroachment of the round ligament on the acetabular cavity; now that attention is drawn to it, some pathognomonic sign may be discovered, and we may be better enabled to select suitable cases for operation.

Conservatism in Operations on the Genitals.

Dr. Howard Kelly's remarks at the combined meeting of the Glasgow and Edinburgh Obstetrical Societies on the importance of conservatism in operations on the female genital organs will, we hope, be widely read. There is, we fancy, little doubt that in the past the relative importance of the uterus, the ovaries, and the tubes has not been correctly estimated, and that, in consequence, sufficient importance has not been attached to the preservation of the ovaries. As Dr. Kelly points out, these three organs may in their entirety be considered to be a complete building of three storeys, of which the tubes are the uppermost floor, the uterus the middle storey, and the ovaries the ground storey. For the complete performance of the genital functions all three storeys are needed. If, however, the upper story has to be removed, the lower two are left and continue to be of use. If the upper and middle storeys are removed, the lowest will still be of use. But, if the lowest is removed, the upper two fall to the ground and are valueless. In other words, if the tubes, or both tubes and uterus are removed, the ovaries can still functionate, and by so doing add to the comfort of the woman; but, if the ovaries are removed, the tubes and uterus cease to functionate, and hence may as well be also removed. Before this fact was recognised, the operation of election in cases of uterine myomata was the removal of the appendages and the leaving of the uterus. Now, this operation is given up for many reasons, one of which being that a woman with her ovaries and no uterus is in a better position than a woman with her uterus and no ovaries. Also in operating for inflammatory conditions of the appendages there is not now the same hesitation in removing the uterus, if by so doing the operation is simplified, that there was formerly when the derelict uterus was believed to be of value.

The Dangers of Water-Gas.

The greatly increased risk to life and health that has arisen from the addition of larger proportions of water-gas to coal-gas have lately attracted considerable attention. In America, the use of this gas is even more common than in this country, and consequently, the number of cases of poisoning by it are also greater. In 1901, 156 deaths from this cause occurred in New York alone. Dr. Pilcher, the resident surgeon at one of the Brooklyn hospitals, in the course of an interesting communication to the Medical Society of the County of Kings, describes, with some detail, the symptoms and results of a series of cases.
which came under his care. Twenty-five cases were admitted to the hospital, and of these six died, at periods varying from eight hours to six days after the exposure to the gas. Only one of the patients who died recovered consciousness before death. In all the cases there was extreme cyanosis, considerable rise in temperature, and increased rapidity in the rate of the pulse and temperature. In the fatal cases the rise of temperature kept pace with the development of pulmo nary oedema. The line of treatment which appeared to be of most value consisted in free venesection, followed by the transfusion of normal saline solution with the object of breaking up the CO haemoglobin. The administration of oxygen did not appear to be of much utility. Strong purges were also administered. In these countries we do not, fortunately, see many cases of water gas poisoning.

The New Journal of the Army Medical Corps.

It is with great pleasure that we welcome the birth of the Journal of the Royal Army Medical Corps, the first number of which appears this month. So long ago as 1864 it was felt that the production of a journal devoted to matters of professional and scientific interest was a necessity if the members of the Army Medical Service were to be kept in touch with one another, and if medical officers were to be afforded a chance of communicating their experiences to the scientific world. For years, however, the "rules and customs of the Service" killed such a project, and all communications by officers were condemned to what the Director-General terms "the limbo of the Army Medical Department Report." Now this is all changed, and the Treasury have at last been induced to give a grant for the working expenses of the journal; a paid editor has been appointed, and the journal has been started in a form and in a manner which will ensure for it the approval and active support of every officer in the corps and of many members of the general body of the medical profession. The present number contains a valuable report on hospital arrangements on board transports, by Captain G. B. Stanistreet, notes on a case of neurectomy of the sciatic nerve, by Lieut. Walter Stephenson, and several other communications. In addition to these, there is a carefully-written editorial on the enteric fever problem, and several pages are devoted to current medical literature. Finally, the journal closes with "Corps News." We are confident that the "hope" of the Director-General will be fulfilled, and that "not one officer will be found in the Corps who does not approve of the objects with which the journal has been founded, or who will refuse it his strongest support."

The Proposed Bazaar in Aid of the Mercer’s Hospital, Dublin.

A circular has been issued signed by several of the governors and members of the medical staff of Mercer’s Hospital, calling attention to the fact that this—one of the oldest of Dublin hospitals—stands sadly in need of funds, and that it is proposed to hold a large bazaar in May, 1904, in its aid. Mercer’s Hospital, or rather the ground on which it stands, dates back as a hospital site to the year 1344, when a lazar house was built there and called the hospital of St. Stephen. The present hospital derives its name from Mary Mercer, daughter of George Mercer, M.D., Vice-Provost and Fellow of Trinity College in 1686. That lady in 1734 settled the large stone house, which had apparently succeeded the lazar house, “by quadruple indenture,” for the accommodation and use of such poor people as laboured under diseases of dangerous and hazardous cure. From that time on the hospital has continued, and although dependent wholly upon voluntary contributions, has done much good work amongst the poor of a very poor district. In the past, many distinguished people worked to assist it. The first performance of Handel’s “Messiah” took place in the Fishamble Street Theatre for the benefit of the hospital. The Charitable and Musical Society gave yearly performances in its aid at which the Lord Lieutenant was accustomed to attend in state, and in 1859 the celebrated Jenny Lind lent her aid to an oratorio in aid of the hospital. It is sincerely to be hoped that the present time will not prove more unfavourable to the prospects of the hospital than has the past, and that the fullest assistance will be given to the governors in the bazaar which they propose to hold.

Antistreptocoocic Serum.

The use of this serum has been, for a good many years now, a very much debated point. The good results, however, which have been recently obtained by Menzer, working in Senator’s Klinik in Berlin, ought to give much encouragement. In his first paper, which appeared about a year ago in the Leitschrift für klinische Medizin, he dealt principally with the treatment of rheumatism, his results being specially good in the chronic cases treated with this serum. He also attempted the treatment of acute cases in the same fashion, but the results were by no means so favourable. In his last paper, which appeared quite recently in the Münch. med. Wochenschr., he has extended his treatment, as he has attempted the injection of cases of so-called chronic pneumonia and of lung tubercle in which there is a mixed infection. His results have been decidedly encouraging and open up a very interesting and valuable field of serum-therapy. As for the contra-indications to the use of this serum, Menzer strongly emphasises the necessity of using great care in the administration in every case, as the proper dose of serum has not yet been accurately gauged, the results with animals in this case not giving any aid in determining the effect on man. One must be particularly careful in cases where there is either a great pleural or pericardial exudation, also where, in phthisis, the disease has progressed as far as cavity formation. With regard to the heart, there are no contra-indications in acute
or chronic endocarditis, in acute or chronic rheumatism, except where there is great enlargement of the heart, and above all where there is endocardial trouble concomitant with stenosis of the mitral valve.

The Responsibility of the Tuberculous Patient.

Now that the consumptive is gradually but surely acquiring the status of an infectious individual with whom it would be desirable to associate on terms of intimacy as little as possible, the question arises as to what extent he is under a moral obligation to inform those round about him of the nature of his malady. The problem is a delicate one, for in spite of the growing tendency of public bodies and health authorities to advocate more generally the notification of phthisis, there are many who believe that by so doing the private rights of the individual are in danger of being outraged. This question does not arise in respect of the acutely infectious fevers, the notification of which is compulsory. The public wrath is rightly stirred up when a flagrant breach of the law is committed, because the evil consequences are more apparent. But the tuberculous patient is permitted to enter places of amusement, to frequent churches, to stay at hotels and boarding-houses without let or hindrance, to travel in exiguous cabins with other passengers on board ship, and even if he himself rightly appreciates the nature of his disease, he is affected by no scruples of conscience by so doing. His responsibility towards his fellow-men is really very great. It is not, of course, implied that his sufferings are to be increased by the ever-haunting fear of being a source of danger to others, but in the light of modern education on the subject it is quite possible for him to be made fully aware of the risks encountered by those with whom he comes into contact should he neglect ordinary sanitary precautions, without causing him unnecessary mental anxiety in this respect. If he conscientiously observe the rules of hygiene laid down for his guidance, there will be no necessity for him to proclaim from the house-tops what disease he is afflicted, while he has the satisfaction of knowing that he is acting in accordance with the highest principles of ethics.

Arterio-Sclerosis and Nervous Diseases.

The connection between certain forms of endarteritis and diseases of the nervous system is gradually becoming more recognised. Obiteration of the cerebral vessels is fraught with the gravest dangers to nervous tissue, and hemiplegia is only too often seen, both in children and adults, as a result of arterial disease. Dr. Allen Starr, of New York, in a paper read before the Practitioners Society of that city, lays stress upon the fact that many of the prodromal features of apoplexy, some of which occur months or years before the actual attack, are mainly due to arterio-sclerosis. The same condition is responsible for many affections of the spinal cord, a fact to which Williamson, of Manchester, was the first to call attention. Many of the symptoms thus produced are often erroneously put down to neurasthenia, so that it becomes a matter of great diagnostic importance to examine thoroughly the state of the cardio-vascular system. Even neuralgia may be due to sclerosis of the smaller arteries accompanying the nerve, as was shown by Dana. Professor Starr points out that in Graves' disease the high-tensioned pulse is absent, and he believes that the low tension is probably due to the excess of thyroid secretion in the blood. It has been found that a corresponding reduction in tension is produced by the administration of thyroid gland in myxoedema. Some analogy can be traced between an attack of migraine associated with high arterial tension and the physical conditions accompanying myxoedema. Dr. Starr, working on these lines, has had some beneficial results with thyroid medication in arterio-sclerosis, and even prefers it to the continued use of the nitrates.

The Xiphisternal Crunching-Sound.

A peculiar pericardial chisel-sound in the lower sternal region was described by Dr. F. J. Brown, of Chatham, in 1856, in a paper read before the Medical Society of London, as "that of a chisel or short plane used forcibly across the end of a piece of timber." Angel Money, Sansom, and Colbeck have since described similar murmurs. Dr. Solis-Cohen, of Philadelphia, records in the American Journal of the Medical Sciences six cases under his own personal observation in which this remarkable sound was heard. The patients were all men, the ages varying between eighteen and sixty-three. Two had indulged in alcohol to excess, and three were heavy smokers. The general symptoms displayed were anorexia, malaise, a certain amount of precordial uneasiness, and some digestive disturbances. The average pulse-rate was 82, and it was regular. The sound is variously described as "crunching," "rough-rubbing," "scraping," or "brushing." Dr. Cohen believes that it is the same sound heard and recorded by the above-named observers, and considers with them that it is, in all probability, due to the presence of "white patches" on the pericardium. That these may, under certain conditions, give rise to stethoscopic signs is admitted by such authorities as Dr. Frederick Roberts and Dr. G. A. Gibson. The associated gastric irritation is believed to be due to the passive congestion of the gastric mucous membrane secondary to myocardial weakness.

The Ignition Vacuum Bottle.

The failure of the various forms of aspirating syringes and exhausting appliances to work at the critical moment has many times been a source of annoyance to the physician. Delay upon such occasions is especially objectionable, not only on account of their urgency, but also because the apprehensions of the patient are rendered greater by the unnecessary prolongation of operative preliminaries. It may be that the mechanism is imperfect, or that the apparatus
has been neglected; but whatever the cause, it is desirable that breakdowns should be avoided in clinical methods, from the point of view of the patient and the physician alike. Dr. Karl Connell, of New York, describes a very simple and inexpensive method of producing a vacuum, all that is necessary being a strong clear-glass five-pint bottle, fitted in the usual way with a perforated rubber stopper, to which is attached a suitable length of tubing. Three drachms of 95 per cent. absolute alcohol are poured into the bottle, which is then tilted so as to allow the whole of the inner surface to become coated with the spirit. The bottle is then placed upright and ignited quickly at the mouth. Directly the flame touches the bottom it is corked immediately. The aspirating needle can now be attached and the apparatus is ready for use. In the New York hospitals it has supplanted the older forms of syphon aspirators, and accidents connected with its use have never been known to occur.

The Dublin Hospitals Report.

The annual report of this Board has been issued as a Parliamentary paper, and from the point of view of those interested in hospital management may be regarded as satisfactory, as the usual tribute is paid to the efficiency and management of these institutions. The report also briefly touches upon the principal causes which appear to “us” to predispose to disease and to tax the resources of the hospitals. In the main the causes enumerated consist of dirt, overcrowding, bad drainage, want of work, and insufficient wash-houses. These are all obvious causes, and to them might be added a less obvious one to which the Board of Superintendence referred in a former report, viz., the scandalous abuse of charitable relief which occurs every day in hospitals. The Board doubtless considered that having referred to this subject comparatively recently, they need not again touch upon it; but it is just one of those matters in which reform will only be effected by constantly and persistently bringing it to the public notice. We trust that in their next report the Board will again draw attention to it, and will also suggest officially to hospital authorities the importance of taking definite steps to prevent it.

A New Clinical Entity.

At the recent meeting of American physicians in Washington, Dr. Osler brought under notice a new clinical entity, a condition of polycythaemia, in which the blood cells average from ten to twelve millions a cubic millimetre. In appearance such persons are livid, as those suffering from morbus coeruleus, or “blue” disease; but they do not suffer from dyspnoea. Happily, the disease is of rare occurrence, and from the cases on record it does not appear in any way to inconvenience those who have it. There is little doubt but that Dr. Osler’s paper will stimulate clinical observation. We find no suggestion made for treatment, and we suppose that the majority of cases will demand little more medication than an occasional saline aperient to remedy the constipation which is usually found to accompany the polycythaemia. The cases recorded so far were old-standing ones of some years’ duration. It would be very interesting to get a report of one in its early stage and learn something of its etiology and of its prodromata.

The Visit of Their Majesties to Ireland.

By the time the present issue is in the hands of our readers, Ireland will be honoured by the presence of their Majesties the King and Queen, on their long-promised visit. In offering them a warm and heartfelt welcome on behalf of the medical profession in Ireland, we are only echoing the universal wishes of the profession, of whatever religion and whatever politics they may be. His Majesty has ever been a gracious friend, not alone to those members of our profession who have the honour to attend upon him, but to the general body of the profession, and to hospitals and other charities with which the profession is so closely connected, and to medical science generally. We regret that the length of his stay will not permit him to visit the Irish hospitals, as did her late gracious Majesty Queen Victoria, but on a future occasion he may confer that honour upon them. His Majesty has been graciously pleased to consent to accept addresses from the Royal College of Physicians and the Royal College of Surgeons.

The “Happy Medium” Operation.

A contemporary draws attention to the fact that there is really little or no accommodation in London for patients with small means requiring a surgical operation, who, on the other hand, do not desire to be regarded as objects of charity, and yet, on the other, who cannot possibly afford the very large fees charged by surgeons of experience. The question is asked whether there be no “happy medium” between an operation costing from fifty to a hundred guineas at a patient’s own residence or in a nursing home, and the same operation performed for nothing at a hospital. In addition to the surgeon’s fees, there are extra fees for assistants, for after-visits, for the anaesthetist, and for the nursing, which, especially if the very high charges of a first-class nursing home or private hospital be superadded, compels middle-class and even some professional people to seek hospital charity under such circumstances. There are two remedies available for the proper adjustment of this only too obvious defect in the hospital system: one is the provision of paying wards or “pay-beds” in ordinary wards in the hospitals, the other is the establishment in different parts of the Metropolis of moderately-priced nursing homes. The former solution of the difficulty does not commend itself, owing to the natural aversion of many people to enter hospitals as patients, and also because the hospital itself very properly demands a considerable weekly sum to cover the cost of actual maintenance, while in many cases it objects to play the part of a nursing home when it was originally intended to be an entirely charitable institution.
The development of nursing homes at "popular prices" would be satisfactory alike to patient and surgeon, as tending to maintain the independence and self-respect of the former, and in the end to attract greater practice to the latter.

Asthma and Morbid Nasal Conditions.

In spite of its strongly-marked characteristics and its common occurrence, spasmodic asthma is one of the diseases about which a great deal remains to be learnt. In severe cases the cough, wheezing, and intermittent dyspnoea, coupled with the sense of constriction in the chest, present a clinical picture of distress and urgency that, once seen, is not likely to be readily forgotten. The spasmodic contraction of the bronchi, which forms the essential morbid factor, may be due either to direct irritation of the bronchial mucous membrane or to reflex irritation. The discovery of the possibility of a remote irritant origin of the malady marked a new epoch in the treatment of asthma. One of the most promising fields of investigation thus opened up has been found in the relationship of morbid conditions of the upper respiratory tract to the symptomatic spasm of the bronchi. For some time past it has been established that by appropriate intra-nasal surgical treatment asthma may be sometimes relieved and sometimes even cured. Good results are obtainable in cases above and beyond those where polypi or other intra-nasal lesions are found by contracting the mucous membrane of the septum nasi. This point is of importance when the small percentage of asthmatics with gross intra-nasal morbid conditions is taken into consideration. At present this method of treatment is empirical, but for all that it affords a reasonable prospect of relief in so many instances that it deserves the careful attention of all medical men who are brought face to face with that most troublesome and rebellious symptomatic complaint, spasmodic asthma.

Anal Stenosis in Children.

That there may exist any degree of stenosis from absolute occlusion of the anus in children to normal potency is obvious to every one who understands the embryonic development of the rectum. But that varying degrees of stenosis do actually exist in practice with any marked influence on health is not so generally recognised. Some clinical observations, however, recently published (a) by Mr. Alan Mackay, of Melbourne, go to show that there is often not sufficient care taken to exclude the possibility of stenosis before treating a child for chronic constipation, and that serious results may follow. In two children seen by him, aged about two years, and suffering from constipation, he found the rectum completely blocked by foreign bodies which had been collected by a partial stenosis of the anus. In one, a glove button had acted as a valve in the opening, and had behind it several pounds of faecal matter, embedded in which were numbers of beads, fruit-stones, fragments of road metal, chaff, egg shells and straw. On dilating the anus and cleaning out the bowel the child was completely cured. In all cases of chronic constipation in young children a rectal examination should be made.

The Indican Reaction.

So far chemical physiology and pathology have not, one regrets to say, been of any outstanding value to the science of surgery, at any rate, in the matter of diagnosis. In the above reaction, however, surgeons have a diagnostic aid which has not, at least in this country, been taken much advantage of. Its application is as a means of determining the approximate site of an intestinal obstruction, as indican only appears in excess in the urine when the obstruction occurs in the small intestine. Some observers record the rather curious fact that the indican is not increased if the obstruction takes place in the duodenum. Of course, obstruction is not the only cause of indican appearing in the urine, but, taken in conjunction with the ordinary symptoms of obstruction, it ought to be a valuable adjunct to the diagnosis of the site. In a recent publication by Ellinger and Prutz, experimental evidence fully backed up the worth of this test, which was proposed by Jaffé many years ago. In connection with this question, it is of interest to note that the substance tryptophane recently isolated from tryptic digestion by Hopkins and Cole appears to be the parent substance of the product which gives rise to indican, viz., indol. The most satisfactory test for indican is that of Obermayer.

The Elections at the Royal College of Surgeons of England.

The admission of voting papers sent by post evidently finds favour with the Fellows, only ten having taken the trouble to attend in person for that purpose. The result of the election to places on the Council was that generally anticipated. As announced last week, the successful candidates were Mr. H. T. Butlin, Mr. G. H. Makins and Mr. C. T. Dent, Mr. F. S. Eve following close on the heels of the last-named. Now that the demand of the members for ad mission to the governing body is in abeyance there is nothing in college politics to excite any particular interest, such interest as is manifested being obviously due to purely personal considerations. The moderate interest felt in college affairs receives further confirmation by the difficulty which is experienced in obtaining a quorum at the annual meeting, and it is probable that these meetings will ultimately be abandoned. The choice of Mr. John Tweedy for the post of President of the College is one which will command general approval. A man of culture, urbane and tactful in his manners, and of liberal views, the influence which Mr. Tweedy will now exercise will unquestionably make for the advancement of this great corporation in its widest and best sense. We

(a) "Intercolonial Medical Journal of Australia," May 20th, 1903.
NOTES ON CURRENT TOPICS.

July 22, 1903.

congratulate Mr. Tweedy on his election, and the College on its choice.

Small-pox in Cambridge.

In spite of the assertion of a contemporary that the report of the existence of an epidemic of small-pox at Cambridge was of the nature of "irresponsible chatter," an allusion possibly to our own remarks on the subject, it is now officially stated that some seventy cases of variola are under treatment in the university city. As we previously mentioned, the cases were for a time diagnosed to be chicken-pox of an unusually severe type, but Dr. Wanklyn, of the Metropolitan Asylums Board, inclined to the view that the disease was small-pox, and the necessary precautions have now been taken. Admitting that the diagnosis in individual cases is often extremely difficult, it is not to the credit of medical science that an epidemic of this magnitude should be allowed to obtain a hold on a persistently mistaken view, and the evil is aggravated by its having occurred in a town inhabited by such a large number of young men, who, if not vaccinated, are likely to prove very susceptible to infection. So far only three deaths are reported, showing that the disease epidemic is of a mild type.

Mixed Bathing.

Public opinion is awakening to the absurdity of the drastic rules enforced in many English seaside resorts against mixed or family bathing, and there are signs that the local authorities at certain popular stations are disposed to take a more common-sense view of the matter. It is obviously absurd to prevent families bathing in common, provided the usual rules as to wearing a suitable and sufficient costume be enforced. Further than that there is no necessity for interference. There should be three separate bathing stations, one for women, one for men, and one for persons who desire to bathe in common, and the selection must be left to individual bathers. In order to overcome one possible objection it would not be unreasonable to insist on separate bathing machines for persons of different sexes, and with that precaution all conceivable objection to mixed bathing disappears. Mrs. Grundy, if she please, may bathe in exclusively female society, but she has no locus standi to interfere with the innocent enjoyment of others less sensitive than this eminently respectable person.

The Finsen Treatment of Lupus.

Since the application of the Finsen light to the alleviation of lupus, instrument makers, with true commercial instinct, have flooded the market with lamps, good, bad, and indifferent, the majority no doubt, as worthless as those of the five foolish virgins of old. It is not surprising therefore to find that Professor Finsen has at last broken silence. In a recent communication he shows that for satisfactory penetration of the tissues efficient lamps must be used. He finds that the best results are obtained by using a current of 60-80 ampères. By employing such, effects may be obtained in from 20-25 seconds, which with a 40-ampère lamp occupied 4-5 minutes. It will be well for operators in this country to overhaul their lamps.

The Germicidal Action of Radium Rays.

A preliminary report states that Dr. Pfeiffer and Dr. Friedberger, of Königsberg, have succeeded in demonstrating the efficient germicidal action of the radiation from radium-bromide. It would seem that the disinfecting properties of these newly-discovered radium rays surpass those of the Röntgen rays. The results of recent investigations seem to go far in showing that real practical service may be the outcome of these researches.

The British Medical Benevolent Fund.

The sixty-eighth annual report of this fund testifies to much useful work, although its scope is necessarily limited by the lack of more ample means. Many of the recipients of relief have once been in good circumstances and have come to want through calamities entirely beyond their control; in fact, the allowances which they receive are often all that stands between them and parish relief. This sad record of suffering and misfortune should stimulate those on whom fortune has smiled to extend its sphere of usefulness by financial support. We are, however, fain to confess that neither providence nor charity are virtues adequately cultivated within the ranks of the profession, and we would gladly see it otherwise.

The new pavilions of the Victoria Hospital, Craigleith, Edinburgh, which we described in a recent issue, were opened last week by Lord Rosebery, who pointed out that, excluding the infant deaths, that is, deaths under five years old, no less than one-seventh of the deaths in Edinburgh are from phthisis.

At the forthcoming annual meeting of the British Medical Association at Swansea, the National Temperance League invite members to a breakfast on Thursday, July 30th, at 8 a.m., Dr. J. Adams Rawlings presiding. Invitation cards may be obtained on application to Mr. John T. Rae, Paternoster House, London, E.C.

The Enno Sander prize of the Association of Military Surgeons of the United States Army has been awarded to Major Frederick Smith, D.S.O., of the Royal Army Medical Corps, for his article on the "Differential Diagnosis of Typhoid Fever in its Earliest Stages."

The twelfth annual dinner of the Incorporated Medical Practitioners' Association was held at the Trocadero on Thursday, the 16th inst.
The death is announced of Dr. J. A. Reedon, Assistant-Surgeon in the service of the Straits Settlements.

The Cancer Investigation Committee of Berlin has instituted a special journal, in which will be published all the latest discoveries relating to this malady.

PERSONAL.

Dr. Robert Reayburn has been elected first President of the recently constituted Medico-Legal Society of New York.

Mr. J. S. Griffiths, of Redland, Bristol, has been created an Associate of the Order of St. John of Jerusalem by H.M. the King.

H.R.H. Princess Henry of Battenberg opened the newly-built Belgrave Hospital for Sick Children, in Clapham Road, on the 20th inst.

Dr. Alfred Hill has been presented with a handsome silver tea and coffee service on his relinquishing the post of Medical Officer of Health for Birmingham.

Dr. G. H. Mouney, of Lincoln, has been presented by his medical friends with a piece of plate as a mark of their esteem on the occasion of his leaving the city after practising there for fifteen years.

CONTINENTAL SUMMER RESORTS.

LAKE LEMAN AND THE RHONE VALLEY.

The Arve is said to be the sole French river which is “heaven-born”; springing not from the ground or rocks, but flowing from the snows and ice-fields of Mont Blanc. So the medical scientists of Champel (where the yellow Arve rushes by to mingle with the blue Rhone) claim for their baths and douches special merit, as their hydro is superabundantly supplied from the Arve stream with the coldest of glacial waters, enriched by copious mineral waters, gathered up en route by the Arve, from the St. Gervais and other springs. Dr. Strehm also asserts that “in their rapid course, continually tumbling over stones and rocks, the Arve waters become saturated with a greater amount of oxygen than the atmospheric air, and acquire by constant friction an important electric tension.”

Champel, a pleasant suburb of Geneva, has two hydrotherapeutic institutions—that of Dr. Tacke, where modifications of the Kneip treatment are given; and the older, better-known Beau-Séjour establishment, presided over by Dr. Glatz, popular with summer visitors here, and in winter at his Belvedere Hotel Hydro, at Nice.

Near Geneva, in the Pays de Gex, the Divonne Hydro is also well known for its cold douches, administered personally by resident physicians, among whom Dr. Roland (speaking English and of great experience with Divonne waters) is in much request by Anglo-American visitors. Not far from Divonne, but perched picture-queely on a projecting spur of the Juras, at 3,500 ft. altitude, and overlooking grand views, is the summer climatic resort of the Grand Hôtel de l’Observatoire, St. Cergues-sur-Nyon, under the able management of Mr. Gimpert, who in winter is likewise at the Belvedere, Nice.

Quite modern in its building and equipment, in a country noted for forests of cedars, and on a fertile plateau feeding much cattle and abounding in flora, the Grand Hotel of St. Cergues offers many inducements for a summer’s sojourn, especially to the cosmopolitan and all seeking rest in a tonic mountain atmosphere of moderate elevation. It is especially situated for an “after-cure” for those who have been under medical treatment at Aix-les-Bains, St. Gervais, Champel, Thoron, Evian, and Divonne.

Across the lake, on the Savoy shore, are the spas of Thonon and Evian. The Thonon alkaline springs (cold, bicarbonated, with resinous odours and traces of copper, iron, and arsenic) merit to be made more known to British visitors. Evian is thronged during the hot months, chiefly by Continentals; and its waters are appreciated for their tonic and diuretic qualities. Among the summer physicians here is Dr. Faibos, of Nice, speaking English, and favourably known to the profession at home and in the Colonies.

From the decks of the steamer crossing the lake, at its widest part, from Evian to Ouchy, the Swiss towns of Lausanne, Vevey, and Montreux appear to advantage; and attention is attracted by the massive arch and great extent of the Palace Hotel at Caux, a truly palatial structure in a superb position. Caux is reached from the steamer-quay and the Jura-Simplon railroad station at Territet, by a cascading road along the rock and pinion railway thence, past Caux, to the Rochers de Naye. The Caux station (3,500 ft. altitude) is on a level with the upper floor of the Palace Hotel, from which an assemv' desceends to the salons, dining-rooms and bed-chambers. The Palace Hotel, an all-year-round residence, built with every latest device for comfort, elegance, and health, ranking high among the luxurious hosteries of Europe, and conducted with appropriate care by the director, Mr. Eulestein.

From every floor the panoramic prospects are widespread and beautiful. The Grand Hotel at Rochers-de-Naye (6,500 ft. altitude) is admirably placed for sunset and sunrise views, commanding excellent prospects over the Bernese, Vaudois, Vaudais, Savoy, and Dauphiny Alps.

At Montreux-Territet are several English physicians, among them Dr. Tucker-Wise (who resides here winters) and Dr. Stuart-Tidey. The city at Florence and Maloja (who practises here all the year).

Leaving the lake at Villeneuve (where is the good Hôtel Byron), the Jura-Simplon railroad proceeds to Aigle, near which the Arve rushes by to mingle with the Rhone. An electric tram runs from the station to the Grand Hôtel, Aigle-ses-Bains, a capital house at nearly 2,000 ft. altitude, amidst attractive shady gardens (a pretty English church in the grounds), and in the immediate vicinity of large beech and pine woods. Connected with the hotel is a well-equipped hydro-annex for alkaline and saline baths and douches, electro-therapy, and scientific massage. The cold bicarbonated alkaline spring here yields very abundantly a water excellent for drinking and medicinal purposes, “diuretic, tonic, digestible,” similar to the springs of Evian and the Vosges. (See Medical Press and Circular of June 10th, this year.)

From Aigle station also an electric funicular ascends to the three Leyasin sanatorium, viz., Grand Hotel Sanatorium (Dr. Exchaquet), Mont Blanc Sanatorium (Dr. Meyer), and Chassolle Sanatorium (Dr. Jaquerod).

These institutions for tuberculous complaints are each of the most modern construction, most comfortable in every respect, open throughout the year, and at altitudes of 4,500 to 4,800 ft., in a locality unexcelled for purity of air.

From Bex station, trams run past the saline baths and springs to Gryon, Chexères, and Villars-sur-Ollon. At Villars is the much- appreciated Hotel of Mr. Freundwiler, who is in winter at his popular Hôtel Alasic-Lorraine, in Cannes. Located about 4,500 ft. above sea-level, the Grand Hotel of
Villars is a very desirable summer home for those wishing a high altitude with an atmosphere tonic, pure, dry, yet remarkably mild.

(Past Bex, and near the ancient town of St. Maurice, are the Lavey Baths, open from May to October, under the experienced care of Dr. Sachez. Lavey is of old and good repute for its strong and abundant sulphur spring (118° F.), having a sodium-potassium base, and adapted to both interior and exterior administration. Hydropathic and other treatments of many kinds are given at Lavey, including a unique pulvisolation, obtained by great pressure from a cold copious spring, 2,200 ft., above the establishment.

In and near the Rhône Valley are a variety of other mineral springs of local fame, the most important being the Leuk Baths, about three hours drive from the Jura-Simplon Louche station and two hours’ walk from the celebrated Gemmi Pass, situated at 4,700 ft. altitude amidst green meadows, in a valley where the sun disappears even in midsummer at 5 p.m.

The Leuk Springs are numerous, impregnated with lignite, and of much efficacy in arthritis and skin diseases. The peculiarities of Leuk is the large mineral water common baths, where patients of all ages and various characteristics are immersed to the waist for several hours daily, promenading therein, eating, drinking, socializing, with playing cards and ping-pong on small floating tables, and gazed upon from galleries by non-invalid spectators, who frequently join animately in the gossips and discussions of the bathers. Sage old Montaigne said a good part of the benefit from a sojourn at a thermal resort was derived from the amusing society and lively conversations found there. Leuk can respond to Montaigne’s idea. But new halls and individual bath-tubs are invading the Leuk, and those admiring “good old customs” should come here soon; and the lovers of the picturesque should select moonlight evenings, when the peripatetic Gemmi rocks stand out weirdly.

From the Rhône Valley are also many summer resorts which are not spas—“health and pleasure” places of great variety and at prices to suit all purses. Among these Zinal is this season drawing many visitors. It is the most readily accessible, from the Sierre Station of the Jura-Simplon railroad, through the Val d’Anniviers. At 5,500 ft. altitude, encircled by some of the grandest heights and glaciers of Valais, and an excellent starting point for mountain ascensions and excursions, Zinal has hitherto been chiefly known to members of Alpine clubs, or to such others who “although on pleasure” bent, had yet “a frugal mind.”

This year, under new management, Zinal takes a new departure, and promises with every succeeding season to gain additional prestige. It has three hotels, (Diablos, Durand, and Besso), and an English church, service in summer.

From the Vige-Junction, the Vige-Zermatt railway ascends the Visp valley. Admittedly one of the most picturesque roadways of the world, and the route to one of the greatest of mountain resorts, its comfortable carriages now are pointed down for the cosmopolitan popularity of Zermatt and of its Seiler hotels increases steadily. As descriptive of its claims to such growing prosperity, we quote from Emile Yung’s “Zermatt and the Valley of the Vige.”

“In this little corner of the world is to be found the wherewithal to excite the curiosity of the learned and to satisfy the aspirations of the artist; to move the most sluggish mind and to strengthen the most desolate soul. For reasons as to physical and restored and, if it were, transfigured, by the reviving breath of the higher mountains. All carry away with them fresh energies and aptitudes for feeling, comprehending, and, in a word, for living.”

HOSPITAL ACCOMMODATION IN GLASGOW.—At the present time the hospital accommodation in Glasgow is being taxed to its utmost. Last week’s report, issued by the superintendent of the Western Infirmary, showed the large number of 441 patients awaiting admission, and the report for the previous week, 409. It was stated in the report of the superintendent of the Victoria Infirmary for last week that 116 were waiting admission. We are glad to know that construction of the Royal Infirmary is to be commenced forthwith, after what certainly appears to be unnecessary delay. The completion of the entire hospital will occupy a considerable time, and will, of course, in no way relieve the pressure for accommodation which at present exists. Soon, at any rate, this will in some degree at least be met for the poor of the City by the large hospital which is in course of erection by the Town Council, and which will have somewhere about 1,200 beds. Small district hospitals are also being built in the Northern and east-end portions of the city.

SMALL-POX IN EDINBURGH AND DUNDEE.—A bad case of small-pox has been reported in Edinburgh. The patient, a man, contracted the disease in Antwerp, and on arriving at Burntisland he was sent on to the Edinburgh hospital. Six cases of the disease are at present in the Dundee hospital, and twenty contacts are in the reception house. What are the precautions? We do not hear whether this is being carried out in Dundee. The epidemic in Glasgow shortly before the opening of the exhibition was quickly stamped out by the extremely energetic measures which were adopted for having the citizens re-vaccinated. The success which followed was most gratifying, and the spontaneous and hearty manner in which the people were vaccinated with the smallpox vaccine by the Health Committee of the city on that occasion has warranted and encouraged the municipal authorities to recommend periodic re-vaccination, which it is to be hoped will be carried out in due course.

GLASGOW SAMARITAN HOSPITAL.—The sum of £1,000 has just been given to this useful institution by Mr. A. Cameron Corbett, M.P., to name a ward in the new wing “The Alice Mary Corbett Ward,” in memory of his late wife, who was president of the Ladies’ Auxiliary Association. A considerable number of the leading ladies of the city have been interesting themselves much in this hospital recently, by having “American tests” at their respective homes, where numerous guests are charged a certain sum, which goes in full to the hospital. In this somewhat unique way a large sum has been collected, and, as we stated some time ago, a bazaar is to be held in the winter for the extension of the institution, and the opening ceremony is expected to be performed by H.R.H. Princess Christian. From its humble beginning only a few years ago, it may truly be said that its lines have fallen in pleasant places. Lord Blythswood and Lord Provost Sir J. Primrose, Bart., and other influential gentlemen are interested themselves in it.

EXTENSION OF GLASGOW UNIVERSITY.—A considerable extension of the university buildings will be commenced shortly for the departments of materia medica, physiology, and medical jurisprudence and public health. The cost, including their complete equipment, will be between £60,000 and £100,000. The site is on the south side of the main road which extends from the front of the present buildings to the Western Infirmary. The style of architecture adopted is a phase of modern Renaissance, selected mostly for its ready adaptability to the requirements of the buildings as well as its simplicity and economy in design. On account of the varied levels of the site it has been possible to arrange the plan so that the second floor plan, the highest in the structure, but only one storey high above the point from which it is entered. The plans have been prepared by Mr. James Miller, F.R.I.B.A. When these extensive buildings are completed, Glasgow University will

SCOTLAND.
be very thoroughly equipped for teaching purposes, and will compare most favourably with any other university in this country.

BELFAST.

THE NEW ROYAL VICTORIA HOSPITAL to be formally opened by his Majesty the King on Monday next, is a building of great interest to all medical men as in many respects the structure is novel. It is built to replace the old Royal Hospital in Frederick Street, and though its position is not so central, it is much better from the sanitary standpoint. It is at the top of Grosvenor Street, on rising ground, with the Dunville Park to the north, and its own grounds, six acres in extent, afford an open space on the south, and adjoin the grounds of the old Asylum for Insane. The new hospital has 300 beds (in place of 180 in the old), and has been designed by Messrs. Henman and Cooper, of Birmingham, in accordance with Mr. Henman’s theories.

The “backbone” of the building is the main corridor, 450 ft. long, running east and west. From it seventeen side corridors open south, each leading to a complete “unit,” consisting of a large ward with fourteen beds, one or two small wards with two beds each, a kitchen, a bath-room, a dressing-room, and either a clinical lecture-room or an operating theatre. The large wards lie side by side, only a dividing wall between two, and are lit by lantern lights in the roof, and a large French window at the south end of each opening on to a balcony and a verandah into the garden. This method of construction is only possible where, as here, the Plenum system of ventilation is adopted. The air is admitted by three openings on each side of each ward, seven feet from the ground, and escapes by a number of smaller openings at the level of the floor. The seventeen units are distributed two each, a male and female, to the four senior surgeons and four senior physicians, and on to the gynaecological unit is on the north side of the main corridor, and contains two wards with six beds each, and an operating theatre with good western light. There are, besides, detached buildings for septic and infectious cases, and a pathological building. Opening off the main corridor on the north are the administration block, including a wing for the resident medical staff and one for the nursing staff, and the external department. The latter consists of a large central hall, lighted from the roof like the wards, and surrounded by about eighteen smaller rooms, including medical (male and female), surgical (male and female), gynaecological, ophthalmic, emergency, recovery, etc.

The two large wings of the administrative block are the only parts of the entire building rising above one storey. No patient need ever be carried up or down a single step. The ventilating system is arranged to give an entire change of air seven times in an hour in winter, and ten times in summer. The cost of the hospital works out at between £300 and £350 per bed— it is hoped nearer the former than the latter.

DOCTORS AS WITNESSES.—At a meeting of the Belfast Board of Guardians on the 14th inst., a letter was read from Dr. H. R. Irvine, a dispensary medical officer, stating that he was summoned as a witness for the Crown at a case in the forthcoming assizes, and that his removal from the Board would do duty for him in respect to the approval of the guardians. The chairman said that Dr. Irvine was continually making such applications, and the ratepayers were again and again having to put their hands in their pockets for him. Personally, he protested strongly against the whole matter. The work was not in connection with the union, but in connection with inquests, and the doctor was no longer required. He thought it would be far better to put the whole matter before the Local Government Board. This suggestion was adopted.

Dr. Louis W. Samson, in the July number of Climate, publishes a valuable paper on the chief diseases-sources of the tropics in their relation to the development of Greater Britain.

Correspondence.

THE HOSPITALS OF UTOPIA.

To the Editor of The Medical Press and Circular.

Sir,—Thinking that your readers may wish to know something of the hospitals of Utopia, to which the archbishop of Canterbury made recent reference, I transcribe the following from a modernised copy of Ralph Robinson’s translations of the right worthy and famous Sir Thomas More’s fruitful, pleasant, and witty work “Utopia.” “In the circuit of the town is a little without the walls, that hath been always so big, so wide, so ample, and so large that they may seem four little towns, which were devised of that bigness partly to the intent the sick, be they never so many in number, should not be too strong or strait, and therefore uneasily and incommodiously; and partly that they which were taken and held with contagious diseases, such as be wont by infection to creep from one to another, might be laid apart from the company of the rest. These hospitals be so well appointed, and with all things necessary to health so well furnished, and moreover so diligent attendance through the continual presence of cunning physician is given, that though no man be sick there, yet notwithstanding there is no sick person in all the city that had not rather lie there, than at home in his own house. When the steward of the sick hath received four meats as the physicians hath prescribed, the best is equally divided among the halls, according to the company of everyone, saving that there is a respect to the prince, the bishop, the trainores, and ambassadors and all strangers. The Utopians were not unmindful of sanitation of Raphael Hystioday tells us of the citizens of Amaurote, the capital, that they did not suffer any thing that is filthy, loathsome or uncleanly, to be brought into the city, least the air by the stench thereof infected and corrupt, should cause pestilent diseases.” And again he tells us that in the vegetable, fish, fowl, and meat markets, “the filthiness and odour thereof is clean washed away in the running river without the city in places appointed for the same purpose.”

I am, Sir, yours truly,

George Foy.

Obituary.

FRANCIS HARRISON WALMSLEY, M.R.C.S., L.S.A.

We regret to announce the death, in his 75th year, of Alderman F. H. Walmsley, which took place on the 16th inst., at his residence, Belmont, Highert Broughton. Mr. Walmsley, who had been in failing health for some time past, was a native of Manchester, being the son of a medical man in practice in the town. He studied at the Manchester Royal Infirmary, and was entered also as a student at the Friar Street School of Medicine, since incorporated in the medical school of Owens College. In 1849 he obtained his diploma, and soon obtained an extensive practice. In 1855 he was appointed honorary and ultimately consulting surgeon to the Salford Royal Hospital, in which institution he always took the keenest interest.

He was first elected to the Salford Town Council in 1864, and he had been the “father” of that body for some time at the date of his death. Discussions of sanitary and educational matters in the Council always found him among the speakers, and on the balance which he displayed on those occasions speedily obtained for him recognition from his colleagues as an authority on questions of sanitation and health. He was placed on the old almanic list in 1874, and he had, therefore, upheld the dignity of the almanic order for nearly thirty years.

Shortly after the passing of the Public Health Act, 1866, Mr. Walmsley submitted to the Council a scheme, which was adopted, for the formation of an health department, and the appointment of a medical officer of health. The question of river pollution entailed much
labour upon a committee of which he was a member, and whose efforts, along with those of other authorities, especially the culminated in the formation of the Mersey and Irwell Joint Committee, which has since been constantly endeavouring to improve the condition of our polluted rivers and streams. He was among the early members of the Joint Committee, and for some time as chairman of its chemical section. Mr. Walmley was appointed chairman of the Health Committee of the Salford Corporation in 1877, and in the same year he became chairman of the River Irwell Joint Committee. As he was, further, one of the Commissioners for dealing with the upper reaches of the Mersey, it will be seen how far-reaching were his efforts with regard to that particular branch of sanitation which seeks to cleanse the water courses of an industrial district.

He was for many years an active member of the first School Board formed in the borough on the passing of the Education Act of 1870. Later he was a representative of the magistrates of the borough among the governors of the Manchester Grammar School, and also sat in the Court of Governors of the Owens College as a representative of the Salford Corporation. His scientific talent led him into an honours secretarialship of the Manchester and Salford Sanitary Association. He was also an old member and ex-president of the Manchester Clinical Society, an ex-president of the Medical Board, and ex-president of the Governing Surgeons’ Association, and a member of the British Medical Association. The Manchester Statistical Society claimed him as a member for a considerable period, and he sat, too, upon the Lancashire Asylums Board and the Asylums Visiting Committee, and was also a member of the Board of Governors of Sir Ralph Pendlebury’s Orphanage at Stockport. The deceased alderman’s magistracy dated back to 1877, and upon the borough Bench, and in every other department with which he was connected, he devoted his time and talents untiringly to the discharge of his duties.

SAML. FARRANT, M.R.C.S., L.A.

The death is announced of Mr. Samuel Farrant, M.R.C.S., L.A., of Taunton, one of the best-known medical practitioners in the West of England, who died at his country residence, Ambergard, Pitminster, aged 65. He had been Mayor of Taunton and Surgeon-Lieutenant-Colonel of the West Somerset Imperial Yeomanry, and was also a member of the Somerset County Council.

Gordon Blackmailing Case

In addition to the list of sub-cripions received and acknowledged in our last issue, the following additional is hereby acknowledged:—

James McWalter, L.R.C.P. 10 0
Robert Woods, F.R.C.S. 1 10
John G. Duffy, L.B.S. 1 10

ANDREW J. HORN, Hon. Treasurer.

The Annual Meeting of the British Medical Association will be held next week at Swansea, on July 28th, 29th, and 31st, with the usual annual dinner on the 28th. The meeting will be preceded by a Cathedral service at 11 o’clock, when the sermon will be preached by the Lord Bishop of St. Davids. On Wednesday, Frederick Thomas Roberts, M.D., senior physician, University College Hospital, will deliver an address on medicine at 8.30 p.m. in the King’s Hall. On Thursday, A. W. Mayo Robson, F.R.C.S., Professor of Surgery, Yorkshire College, will give an address in surgery at 2 p.m. The scientific work of the meeting will be conducted in eleven sections, viz., medicine, surgery, obstetrics and gynaecology, state medicine, psychology, pathology, ophthalmology, diseases of children, laryngology, tropical diseases, Navy, Army, and Ambulance. The sections meet Wednesday, Thursday, and Friday, from 10 a.m. to 1 p.m., and the work promises to be active and of unusual interest. The General Meeting of members will be held in the King’s Hall, on Tuesday, July 28th, at 2 p.m., when the President will be elected.

The summer general meeting of the Irish Medical Schools’ and Graduates’ Association will be held at 2.15 p.m., on Wednesday, July 29th, 1903, in the board-room of the Higher Grade School, Swans, the President, Dr. P. S. Abraham, F.R.C.S.I., in the chair. One of the items on the agenda paper is: “To consider what action the Association should take towards assisting the removal of the grievances of Irish dispensary doctors.”

The Fourteenth International Congress of Medicine, Madrid, 1903.

A MEETING of the National Committee of Great Britain and Ireland was held in the rooms of the Medical Society on Wednesday, July 15th, 1903, Dr. Pavly, F.R.S., the President, in the chair. A report was read about the Madrid Congress, stating that 238 persons had enrolled themselves members of the Congress from the United Kingdom. Of this number 150 were present in Madrid, of whom several were appointed to honourable offices in various sections of the Congress. It was noticed with regret that certain radical alterations had been made in the constitution of the Congress without any previous consultation with the National Committee for Great Britain and Ireland. The second article, for instance, of the General Regulations for the last Congress enacted that the Congress shall be composed of medical men, pharmacists, veterinarians, and other persons practising one of the different branches of medical science, and that anyone who holds a professional title shall be admitted to take part in the Congress on the same terms as members of the medical profession.

The admission of a large number of members apart from medical men made the Congress unwieldy in point of size, and to a large extent frustrated the objects for which it was founded. It was further reported that much confusion had been caused by the omission of the Congress authorities to communicate the names of the official delegates to the National Committee. It was said that the resolution to which the report was referred to be brought from the Medical Society of London suggesting certain alterations in the constitution and duties of the National Committee. A letter was referred for consideration to a sub-committee consisting of the President (Dr. Pavly, F.R.S.) and the two
secretaries (Dr. P. Horton-Smith and Mr. D'Arcy Power), Sir John W. Moore, M.D. (ex-President of the R.C.P.I.), Sir Dyce Duckworth, M.D. (Treasurer of the Royal College of Physicians, London), Dr. Alchin (ex-President of the Medical Society of London), and Dr. J. F. Sutherland (Deputy Commissioner for Lunacy in Scotland). The meeting adjourned after passing a vote of thanks to the Medical Society of London for the use of the rooms.

Central Midwives Board.

A meeting of the Central Midwives Board was held at the Privy Council, Whitehall, on July 14th, 1903. Dr. Champsneys being in the chair, Dr. J. R. Kaye, County Medical Officer for the West Riding of Yorkshire, Dr. G. Reid, County Medical Officer for Staffordshire, and Dr. Shirley Murphy, County Medical Officer for London, attended as a deputation from the Conference of County Medical Officers in order to make certain suggestions with reference to the administration of the Act in county areas. At the conclusion of the discussion the chairman thanked the members of the deputation for their attendance and for pointing out how certain difficulties in the administration of the Act might be overcome.

Suicide of an English Practitioner at Ostend.

Mr. Hunter Urgunait Walker, L.R.C.P., L.R.C.S. Ed., was the subject of a shooting last week at his house in London, while on a visit to Ostend. Mr. Walker was the divisional surgeon of police for his district and medical officer to the Hackney Public Dispensary. He was a popular man, a large practice, and no reason is assigned for the act.

The Supply of Vaccine in Scotland.

In reply to the deputation who waited on him to urge a better provision of vaccine lymph for Scotland, Lord Balfour of Burleigh (the Scottish Secretary) could not undertake to do anything towards it, but the supply of vaccine lymph was an Imperial matter and could not be dealt with in respect of any one division of the Kingdom. He added that, as in England, public vaccine was not supplied with Government vaccine; moreover, whereas in England 56 per cent. of the total vaccinations were performed by public vaccinators, in Scotland only 2 per cent. had recourse to their services. He declined to be a party to any step likely to extend the English system to Scotland. Moreover, no complaint had been made against the lymph in general use in Scotland, and for the time being he declined to commit himself to any statement on the question of the quality of the lymph.

Odontological Society of Great Britain.

St. Bartholomew's Hospital Medical School.

At the distribution of prizes last week the following awards were made inter alia:—The Kirkes Scholarship and gold medal to Mr. C. M. H. Howell; the Brackenbury Surgical Scholarship to Mr. F. J. Faulder; the Brackenbury Medical Scholarship to Mr. C. H. Howell; and the Lawrence Scholarship and gold medal to Mr. A. A. Meaden.

Dinner to Professor J. McFarland, of Philadelphia.

Dr. J. McFarland, professor of pathology and bacteriology in the Medico-Chirurgical College of Philadelphia, was passing through London last week, and some medical friends took advantage of the opportunity to entertain him at dinner in the Louis XV. room of the Hyde Park Hotel, Albert Gate, S.W., on Tuesday evening. The chair was taken by Dr. Alfred S. Gubb, who was supported by a number of well-known members of the profession. Among those present were Dr. Thomas, Dr. F. J. Allan, Dr. F. S. Palmer, Dr. A. E. Giles, Mr. W. McAdam Eccles, Dr. H. Campbell Thomson, Mr. G. Lenthal Chettle, Mr. de Santi, Mr. Percy Dunn, Dr. Rolleston, and Mr. F. W. MacAllister. In proposing the health of Dr. McFarland, Dr. Gubb insisted on the cordial feelings which the profession in Great Britain felt towards their American confrères and on the benefits likely to accrue from such opportunities of international intercourse. Mr. McFarland responded to the toast in his honour by a humorous speech and a very agreeable evening was spent.

University of Glasgow.

The following have passed the fourth (final) professional examination:

(A.)—For M.B., C.M. Charles Lorn Stewart Gibson.

Conjoint Board for Ireland.

The following candidates have passed the second professional examination of the Royal Colleges of Physicians and Surgeons:

An interesting lawsuit is down for hearing to-day at the First Chamber of the Civil Tribunal, Paris, which was called upon to deliver judgment brought by Mr. Bertie Marriott, a well-known Anglo-French journalist of thirty-three years' standing, against Dr. Ferré, of the Bicêtre Asylum. The plaintiff was placed under restraint as of unsound mind at Charenton for the period of fifty-seven days on the certificate of the chief physician at Bicêtre. He only regained his liberty, it is asserted, through the intervention of the British Embassy. The damages are laid at 50,000,
NOTICES TO CORRESPONDENTS.

JULY 22, 1905.

Correspondents requiring a reply in this column are particularly requested to make use of a distinctive signature or initial, and to avoid the practice of signing themselves "Reader," "Subscriber," or "Our Subscriber." Much confusion will be spared by attention to this rule.

Contributors are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland or in the Dublin office, in order to save time in re-ferencencing from office to office, when sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ERRATA.—Reprints of articles appearing in this journal can be had at a reduced rate, provided authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

Original articles or letters intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

R. J. C. McWALTER—Your paper is marked for early publication.

ERRATUM.—In the article "The Medical Treatment of Pertussis" in last week's issue, page sixty-seven, the belt recommended should read " released" instead of "relaxed." D. Eden (Budapest)—Communication to hand. D.D. (Paris)—Regret the additions to your paper arrived after the journal had gone to press.

FIN PINE LINE.

Young Doctor: "I find it hard to draw the line between a common cold and chronic bronchitis."

"He is right, my boy. Social distinctions have to be made—there's no help for it." (C. & B.)

M. R.—You should apply to the secretary of the fund, who will doubtless furnish the information you require and which we are unable to supply.

D. R. C.—Your MS. has been received and will receive attention.

THE ANNUAL TEMPERATURE BREAKFAST.

To the Editor of the Medical Press and Circular.

Dear Sir,—I shall feel obliged if you will kindly allow me to express my entire satisfaction with the invitation to this Annual Temperature Breakfast, by invitation, which I have been made by the National Temperance League, and which I shall be glad to attend, if you will be so kind as to send me a ticket.

Yours faithfully,

J. R. R.

Paternoster House, London, E.C.

July 15th, 1905.

JOHN T. RAN.

Secretary.

THE SCOTCH QUARRY MEDICAL DISPUTE.

The secretary of the medical committee representing the quarrymen at Ballachulish, whom unanimously object to the arbitrary dismission of one of their officers, is now addressing the following protest:

To the Members of the Medical Profession.

We, the Medical Committee representing the 400 quarrymen at Ballachulish and quarry assistants, have now written to our readers that we will not accept the services of any medical officer, who is not appointed by our- selves.

ANDREW CLARK.

Ballachulish.

16th July, 1905.

Appointments.

BONY, W. F. VICTOR, M.R.C.S., L.R.C.P., Colchester.

BUTCHER, J. S., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., Assistant Resident Medical Officer to the St. Mary's Hospital for Sick Children, Charing Cross.

DUKE, JOHN BEATTY, M.A., Cantab., M.R.C.S., L.R.C.P. Lond., Resident Medical Officer to the Royal United Hospital, Bath.

HANLEY W. SAMSON, M.R.C.S., M.D. Lond., F.R.C.S. Eng., to the Richard Hollins Research Scholarship in the Cancer Department of the Middlesex Hospital.

HARRISON, T. H. J., F.R.C.S. Eng., Medical Officer in Charge of the Light, X Rays, High Frequency Departments, &c., to the Hospital for Diseases of the Skin, London.

LAZARUS-BARLOW, W. S., M.R.C.P. Lond., Director of the Cancer Research Fund, Middlesex Hospital.

O'Quin, W. M., M.B., C.M.Aberd., Assistant Senior Medical Assistant to the Greyfriars Asylum and Mental Hospital, Walthamstow, Surrey.

PLATFORD, HUGH JAMES MOORE, M.R.C.S., L.R.C.P. ENG., to the Royal Free Hospital, Middlesex.

PLUNKETT, H. J., F.R.C.S. Edin., Assistant Obstetric Physician to King's College Hospital.

REED, WALTER HUGH, M.R.C.S., L.R.A. Lond., Medical Officer of Health to the Westbury (Wiltshire) Rural District.

Vacancies.

Ballyshannon Union.—Medical Officer. Salary £160 per annum, with vacation fees; also to act as Medical Officer of Health at a salary of £200 per annum. Applications to J. B. Chism, Clerk of Union. (See adv.)

University College of South Wales.—Professor of Anatomy. The salary is £300 per annum. Applications to J. Austin Jenkins, B.A., Registrar, University College, Cardiff.

State of Sarawak.—Government medical officer for the tropics. Three years' agreement. Salary £800 per annum and month free quarters. Unmarried and not more than 28 years of age. Applications, the Borneo Company, Sarawak Government Agents, Esq., Fenchurch Street, London. Metropolitan Asylums Board.—Second Medical Officer at the Asylum at Tottington Sec. Salary £450 per annum, rising to £600, with rations. Forms of application at the office of the Board, Embankment, London, E.C.

Somerset and Bath Asylum, Cottow, Taunton.—Assistant Medical Officer. Salary £150 per annum, increasing to £200, with apartments, board, and washing. Applications, to the Secretary, General Post Office (Medical Department).—Second Assistant to the Medical Officers. Salary £100 a year, rising to £125, as to the duties can be obtained from the Chief Medical Officer, London. Bensavenous Workmen and Agents Doctor's Fund Committee require on the 1st day of Oct. next, 1905, the Services of a Gentleman to take charge of a large Charitable and Ironworks Practice. Salary £500 per annum, with free house, etc. For further particulars apply to the Secretary, Mr. William Griffiths, Esq., New William Street, Bensavenous, Mon.

Nottingham General Dispensary.—Wanted, at once, Assistant Resident Surgeon. Salary £350 a year, with board, washing, etc. To apply to Dr. Briers, Bensavenous, Mon.

Clayton Hospital and Walsden General Dispensary.—Junior House Surgeon. Salary £250 per annum, rising to £350, with board, washing, etc. Applications to the Hon. Sec., Clayton Hospital, Walsden. East Suffolk and Ipswich Hospital, Ipswich.—Salary £210 per annum, with board, lodging, and washing. Applications, with testimonials, must be received on or before 26th July.

Haydock Lodge Asylum, Lancashire.—Assistant Medical Officer. Salary £300 a year, with board, washing, etc. To apply to Dr. Briers, Haydock Lodge, Newton-le-Willows, Lancashire.

Births.

GIRLINGTON.—On July 18th, at Holly House, Birrell, Leics, the wife of Charles J. Girling, M.B. (Lond.), of a son.

FRANK.—On July 7th, at Fuchsia Cottage, Camberwell, to Ada Elizabeth and S. Edward Pedley, M.R.C.S., L.R.C.P. Lond., of a son.

Marriages.

ACKERLEY—RAVENHILL.—July 14th, at St. Mark's Church, Surbiton, Richard Ackerley, M.A., M.B., of Croft House, Surbiton, to Constance Mary, youngest daughter of the late William Waldron Ravenhill, Barrister-at-law, of Surbiton.

CARRY—BLAKE.—On July 9th, at Wivenhoe Church, near Colchester, Conrad de Bille Carry, B.A., M.B., M.R.C.S., of Guernsey, to Emmeline A. M. Blake, only daughter of the late Rev. W. Ashton Blake, of Moton, Suffolk.

CALLENDER—HOODON.—On July 15th, at St. John's Church, Sidcup, Thomas Marshall Callender, M.D. (Edin.), to Charlotte Eliza Marie Rose, eldest daughter of the late Rev. W. S. R. Hoodon, of Sidcup (who is unmarried, but not bat- tised), Sidcup.

HARVEY—BOW—On July 16th, at St. Mary's Church, Wimborne, Alexander Harper, M.D., of Eastbourne, son of James F. Harper, M.D., of Hertford street, Mayfair, and West Norwood, to Constance Evelyn, daughter of Charles Bow, of Hospital, at Byfleet, Weybridge—MACPHERSON.—July 7th, at Christ Church, Bromley, Arthur Ernest Ralph, M.R.C.S., L.R.C.P. Lond., of a daughter Mary Stewart, eldest daughter of Robert Macpherson, Bromley.

SQUIRREL—ADAMS.—On July 16th, at St. Nicholas Parish Church, Kenilworth, James Harry Sequeira, M.R.C.S., L.D.O. to Nellie, daughter of Mr. and Mrs. J. S. Adams, of the White Lodge, near Stafford.

SPOONER—BRADLEY.—On July 16th, at St. George's Church, Bloomsbury, William Caswell Spooner, M.R.C.S., eldest son of the late Edward Monro Spooner, M.D., of Blunderville, Dorset, to Edith Maud third daughter of the late William Tenny Spooner, increased B. of Chichester, and the late Mary Bradley of Lynnwood, Fareham, Hants.

Deaths.

GOVLISH.—On July 16th, at Park Bungalow, Minchinhampton, Margaret Elizabeth, widow of Daniel Glegg, M.D., of Morton on the Marsh, Berkshire.

WALK.—On July 14th at Leuwhoe House, Chackle, Stoke-on-Trent, Henry Langley Webb, M.R.C.S. Eng., L.R.A.
Original Communications.

ATONIC DYSEPSIA. (a)

By Prof. A. H. CARTER, M.D., F.R.C.P.,
Senior Physician to the Queen's Hospital, Birmingham.

GENTLEMEN,—The subject upon which I am announced to address you this afternoon is "Atony of the Stomach and its Treatment and Management." When, however, I came to gather my ideas together on the subject and to put them into shape, I found that the term "atony" was, perhaps, a little too narrow and restricted for my purpose, and therefore I thought it desirable to substitute the term "motor insufficiency" for "atony," as being somewhat larger in its connotation, and somewhat better adapted for the object I have in view. Now, atony and motor insufficiency are by no means convertible terms. It is perfectly true that motor insufficiency invariably occurs where there is atony, but motor insufficiency is a functional sign which may arise under different circumstances. Under no circumstances do we find it occurring as a primary condition. Reduced to its simplest expression, motor insufficiency is, I take it, simply a difficulty, and therefore delay, on the part of the stomach in getting rid of its contents. Now every degree of delay may be met with from a length of digestive period which is scarcely in excess of that which is required under normal conditions for the digestion of a good meal, up to a condition in which the stomach cannot get rid of its contents at all. It would seem, therefore, at first sight, impossible to classify a condition exhibiting so even a gradation. But two well-marked groups may be recognised, according as the stomach empties itself once in the twenty-four hours or not. On the first occurrence of motor insufficiency, the prolongation of the digestive period may be such that it may not interfere with digestion at all—by which I mean that the interval between any two consecutive meals is such that although the process of digestion is slow, still the stomach manages to empty itself before the next meal.

Under these circumstances there is no reason that there should be any symptoms at all; but as soon as the delay is increased beyond this point, you begin to get symptoms. It is absolutely necessary that the stomach should have an interval of rest in which to prepare for the work it has to do; and it is impossible for that work to be done comfortably and effectively if further food is introduced into the stomach before the last meal has been disposed of. The interval between the last meal in the day and the first meal on the following day is so long in comparison with the time separating any other two consecutive meals, that a patient will for a long time complain of a trouble which is confined to the day, and which is put right at night by the fact that the stomach has time to empty itself and start fair again on the following morning.

(c) Abstract of a Clinical Lecture delivered at the Medical Graduates' College and Polytechnic.
108 THE MEDICAL PRESS. ORIGINAL COMMUNICATIONS. JULY 29, 1901.

the stomach. If malignant, the obstruction is produced by malignant disease of the pylorus. To secure a dose for patients with cases of:
1. Those in which the motor insufficiency depends upon simple atony.
2. Those in which it depends upon atony with gastric irritis.
3. Those in which it depends upon some simple direct or indirect mechanical obstruction.
4. Those in which it depends upon malignant disease of the pylorus.

The common divisions do not admit of a hard and fast distinction. On the contrary, two or more of them are often present in the same case. Thus the fermentative processes associated with well-marked atony may give rise to gastric irritis, or, as an aid to diagnosis in a case complicating with atony, or, again, atony may lead to displacement of the stomach and relative obstruction, while pyloric obstruction almost always, sooner or later, leads to marked atonic relaxation.

The lecturer then gave a short clinical sketch of a fairly typical case of each of these four conditions, and also related a case of partial pyloric obstruction from celiacal contraction following upon an old ulcer close to the opening.

I now pass on to a brief consideration of the general diagnosis of motor insufficiency in reference to the circumstances of its occurrence. First of all, we have to determine the existence of motor insufficiency. All signs available for this purpose there is no doubt with certain precautions that the splashing sounds obtained on succession may be relied upon as the most characteristic. This is known as Chome's sign. For its validity two conditions are essential: First, that it exists throughout the digestive period, and this makes it a measure as well as the index of motor insufficiency, for as long as you get the sign there is something in the stomach that is not got rid of, and therefore if you obtain splashing sounds in the morning you know that there must be retention, and, on the other hand, if Chome's sign is unobtainable in the morning, in all probability if there be motor insufficiency it is a case of simple stagnation. Of course, you must make allowance for those cases in which the abdominal walls are very thick, and those in which a nervous person keeps his abdomen very tense. Such cases must be carefully distinguished from those cases in which acidity is present. Wherever the tube can be passed you will get evidence that is, of course, of a much more conclusive nature. People in this country do not talk readily to the tube, and if you went about with a tube in his pocket to put down the throat of every patient who happened to consult him for indigestion would rapidly lose what practice he had managed to obtain. Still, for educational purposes, in medicine, for example, the taking of a tube, if not more necessary than in dealing with diseases of the stomach. Avoid getting into that common habit of ordering drugs—whether acids or alkalies—simply because a person complains of dyspepsia. Examine the case with a view of eliciting the causes. Get some idea of how the patient lives and passes his day. The things to look to are the actual amount of food taken at one meal, the time occupied by the meal, the degree of the trouble, the taking of or the absence of the day's meal, the nature of the work and business of the patient, the conditions under which the work is done, the exercise taken, the arrangement of clothing, and the question of corsets in dealing with women, the condition of the stomach, the amount of simple indigestion in women arises from the way in which they dress. In such cases of dyspepsia I am strongly of opinion that an abdominal support which presses the abdomen upwards instead of downwards should be provided for the curious, if it is possible to persuade the patient to wear it.

With regard to diet in simple stagnation or motor insufficiency of the first degree, the most important thing is to give a diet of such a quality and quantity that the stomach shall empty itself before the next meal. That may be done in one of two ways, either by giving small quantities and rather frequently, or by lengthening the intervals between the meals. Permanently the latter is the better plan for getting enough nourishment into the tissues. In an ordinary case of atony the best plan is to begin with a glass of hot water in the morning; this helps the stomach to empty itself and start fair on the day's work. Do not let a meal be taken for at least an hour afterwards, during which 15 or 20 minutes' exercise may be taken. Then a plain breakfast consisting of cereals with a little milk, such as are shredded wheat, is best tolerated. Of course, the use of tea and milk if the stomach will tolerate it; very little fluid must be taken with the meal. This may be supplemented if necessary with a little state bread, plain or toasted, with some fatty food, which is the best thing to give at the beginning of the day. Nothing should be taken after breakfast before the middle-mid-day meal, except, perhaps, a glass of hot water. At the mid-day meal you must be careful to
avoid all easily fermentable foods, and keep almost exclusively to nitrogenous food, but in an ordinary case of simple stagnation you may generally give some carbohydrates. Otherwise the "paddling course" must be avoided. Very little must be given in the shape of fluid. In atony a little alcohol may be desirable, either diluted spirit or light wine, but in phosphates and bicarbonates of sodium. Two ounces of the former with half an ounce of the latter are pounded up so as to make a fine powder, and the dose is one teaspoonful in a glass of hot water in the early morning. This does not irritate the stomach and is very efficient in many cases. Medicines I have left to the last because that is the position of their usefulness in these cases. In the above forms of obstruction, strychnine is far and away the most beneficial and valuable. In the severer forms of motor insufficiency, where there is fermentation, you must rely in the first place as far as possible on nitrogenous, proteid food-stuffs, for these are the foods which a fermenting stomach takes to best. Any fat, carbohydrate, or succulent food at once gives rise to fermentation. With not bulky but fairly concentrated proteid foods (meaty food) you can sometimes get along fairly well, but, of course, a patient this dose for a great length of time, and it is then a good plan to supplement with rectal nutrient injections, containing fat and starchy matter. By this means you can very often keep up the nutrition of your patient. The dilemma is this: if you give enough carbohydrate food to effect proper nutrition, the stomach is upset, and if you only give as much as the stomach can bear, the patient is imperfectly nourished.

With regard to antisepsics, I do not believe much in medicinal antisepsics. Resorcin is the one that suits best, but all antisepsics are more or less irritating to the stomach. However, if the stomach can bear them, you have great advantage.

The last part to which I would refer is the use of the tube. In any case of well-marked retention, I am quite sure that you cannot do justice to yourself, the complaint or its treatment without occasionally washing out the stomach, and the best time for doing this is in the early morning.

Gentlemen, I must apologise to you for the fragmentary nature of my lecture, which was unavoidable, both from the extent of the subject and the short time at my disposal.

SERUM-THERAPY
IN THE
TYPHOID FEVER OF CHILDREN.

By Dr. ALBERTO JOSIAS,
Physician to the Bretonneau Hospital, Paris. (a)
*Specially reported for the Medical Press and Circular.*

The discovery of the antitoxin serum of diphtheria marks the beginning of a new era in medicine. The success naturally led to the prosecution of research for the discovery of the antitoxin of typhoid fever. Chantemesse and Widal, in 1892, took the initial steps by inoculating guinea pigs with gradually increasing doses of bacillary cultures of the typhoid bacillus, living and dead, and finally obtained a serum which possessed prophylactic properties, that is to say, it conferred protection on animals, so that they bore a lethal dose of the typhoid toxin; but it did not neutralise typhoid in the human being. At the 1898 International Congress of Medicine at Madrid, Chantemesse announced that by cultivation of the products he had secured a toxin from which, by the removal of the bacilli by filtration, he got an antitoxin possessing both phlogistic and curative properties. He now had a working formula, and could produce the circulating antitoxin, useful and advantageous, for its production, and the effects of heat and oxygenation on its properties.

(b) Paper read at the International Medical Congress at Madrid.

D
He found the horse very susceptible to typhoid toxin and slow and difficult to immunise; he therefore experimented no more with it. From his experiments on animals, and from the use of it as a therapeutic agent for human beings, he from the first concluded that in the typhoid antitoxin we had a powerful prophylactic and curative remedy. His experiments threw a great light on the action of typhoid antitoxin and its activity as the following experiments illustrate. He took two rabbits, one of whom he injected with the antitoxin, which we will call the protected rabbit, and the other remained unprotected. Both animals were inoculated with emulsion of typhoid bacilli, the protected animal receiving a dose twice as large as the unprotected one. In six hours the serum of the unprotected rabbit was found to be as rick in Eberth's bacilli as if it were a gelatine culture, the serum of the protected one was rich in mono- and polynuclear leucocytes, in the protoplasm of which the typhoid bacilli were found motionless. From this he concluded that the antitoxin, by arresting the functional activity of the bacillus, played the part of a true preventive. The curative action was, in his opinion, shown by the survival of the protected animal under twice the dose of the toxin that produced fatal results in the unprotected one in thirty-six hours.

The antitoxin treatment cannot, however, be deferred too long; if postponed until the typhoid poison is producing its full physiological effects the reaction is intense. The leucopenia so marked in the course of the unprotected animal was not found in that of the protected one. It is fair from the above experiments to conclude that the anti-typhoid serum of Chantemesse has both antipathogenic and curative properties. It intensifies the activity of the phagocytes and leucocytes, and stimulates their production, and it also appears to have a physiological excitant action on the lymphatic system. To secure its therapeutic action it should be administered early in the disease and in doses sufficiently large to counteract the severity of the attack. Has the typhoid antitoxin a prophylactic and curative influence on man? This question cannot be answered until a comparison is made by careful and prolonged observation of the results obtained by the serum treatment and the older remedies. To make this comparison, Chantemesse for twenty months devoted himself to the study of the typhoid fever mortality tables of the Parisian hospitals, and spent twenty-nine months in the examination of those of Bastian. In the Bastian Hospital the administration of anti-typhoid serum and the use of the cold bath by the patient, the hospitalisation of the patient, and the usual pharmacological remedies are used. Here are the results of his industry:

From April 1st, 1901, to December 31st, 1902, there were 1,478 cases of typhoid fever in the hospitals of Paris, of which 286 died, giving a mortality of 19.3 per thousand.

From April 1st, 1901, to December 31st, 1902, M. Chantemesse treated in the Bastian Hospital 186 cases of typhoid, of which 7 died, giving a mortality of 3.7 per 1,000.

These results were so much better than those obtained in the Parisian hospitals that he ascribes them to the anti-typhoid employed by the cold bath with the patients to whom the anti-typhoid serum was administered, some have said that the good effects were due to the baths and not to the serum. This argument will not, however, bear examination. M. Chantemesse has found that under the most perfect hydroathic treatment the statistics of the hospitals never showed a less mortality than 12 per thousand.

The complications in the cases treated by M. Chantemesse have been few, with the exception of a perforation of the small intestine, which occurred five times in the 1,86 cases. From an examination of the statistics of the Bastian, Gratt and Co., he finds that perforation of the small intestine occurs in 2.75 to 3.00 per cent. of cases.

Including the cases under the care of M. Chantemesse in Toulon, as well as those in Paris, the number treated amounted to 507, of whom 30 died, a mortality a little under 6.0 per cent. The cases in which perforation occurred were those in whom the inoculation was not made until the ninth or twelfth day of the disease. Not a single case of perforation occurred in those cases in which the anti-typhoid serum was administered early in the disease, due to the nature of the intestinal wall, which, as a rule, commences at the beginning of the second week. If the serum is to be of use in such cases it must consequently be introduced in time to prevent the gangrene spreading into the whole thickness of the intestine. M. Chantemesse tells of the good results he has had in osteitis and periostitis occurring during convalescence by the injection of one or two doses of the antitoxin repeated at five-day intervals.

Before submitting to the Committee the final statistical results of his treatment carried out in fifty cases of typhoid fever in the Hospital for Children in Paris, the Hôpital Bretonneau, I will place before you a short letter from Dr. Chantemesse summarising the observations and clinical studies in the serum-therapy of typhoid fever. The accounts published were so encouraging that I had no hesitation in adopting the remedy in the treatment of my little patients, in whom I am glad to say, no minor accidents occurred. I commenced the treatment boldly, not tentatively, and of the fifty children so treated, some few of them suffered from polymorphous eruptions similar to those following the use of antitoxin of the typhoid bacillus, the serum used being that known as Lier's. For twenty-four hours after the inoculation the diet should be confined to water and two or three litres of a light fruit drink. During the second twenty-four hours a light meal is allowed and in the third twenty-four hours the amount of milk may be increased to two litres, and on the fourth day milk and broth may be substituted.

When the temperature rises to 102.5 or 102.8 F. the child gets a bath, the water being 72 F.; when the temperature does not reach such a height we confine ourselves to cold sponging of the body. This combination of serum inoculation and cold bathing, or sponging, is our routine treatment when the diagnosis of typhoid is made, either by Widal's test or by the presence of the rash. The effect, in each case, of the serum is tested by a mixture of a drop of typhoid serum and fifty or a hundred drops of the Eberth suspension. The characteristic reaction was obtained in forty-five cases out of the fifty. The serum injections were made at the stated intervals as follows:—Three children were injected on the sixth day of their illness, five on the seventh day, ten on the eighth day, seven on the ninth day, eight on the tenth day, five on the eleventh day, three on the twelfth day, two on the thirteenth day, one on the fourteenth day, three on the fifteenth day, one on the sixteenth day, and one on the seventeenth day.

As a rule, the inoculation was found to influence the temperature curve; a descent was noticed on the day of the injection and continued for many days; also continued daily until convalescence. In some serious cases, however, the fall of temperature which took place for a few days after inoculation was not
maintained; but the temperature did not afterwards attain to a dangerous pyrexia. The marked constitutional disturbance occurred after inoculation, without any subsequent elevation, took place in fully one-third of our cases. We conclude that the best results are obtained when the serum is used at the beginning of the disease. The typhoid fever of 1897 at Châlons was marked by an early toxemia. Patients who have been inoculated before the seventh day of the attack make a good and quick recovery. In those cases where inoculation was not performed until after the fifth day the pyrexia was not so marked and the duration of the fever was greatly prolonged, reaching to thirty and even thirty-nine days. In a great majority of the cases the initial injection was sufficient. In a few cases of a decomposed type of typhoid fever, the disease did not appear to influence either the temperature or the duration of the fever. But in the great majority of them the inoculation plainly lessened the temperature and cut short the attack. In the case of children it is difficult to get the urine kept, and to estimate the quantity passed in the twenty-four hours; but from what we could learn we believe that the inoculation did not diminish the amount, neither could we find more than a rare with marked prostration, in the secretion, and in no case did we meet with nephritis.

The symptoms and effects that follow from the use of antitoxins in the treatment of disease call for careful observation from many standpoints. I have been able to find some observations on the use of the anti-typhoid toxin, in all of which the subcutaneous injection has been followed by a gradual fall of temperature until it reached the normal. I have noticed a slight relaxation, a more or less recurrence of a very mild type of the fever, which disappears in four or five days, or ten at the most. But for this there seems no other reason than the elimination of the serum from the system. In four of our fifty typhoid patients treated by the anti-typhoid toxin I have had relapses; in three cases it occurred on the twenty-second day after the subcutaneous injection, and in one case on the ninth day. These relapses have all been of short duration and of a very mild type. Complications are the exception.

In one case, however, there was perforation of the bowels, followed by death: in this case the subcutaneous injection was not given until the ninth day of the illness. Of fifty typhoid patients treated by the anti-typhoid toxin I have had relapses; in three cases it occurred on the twenty-second day after the subcutaneous injection, and in one case on the ninth day. elucidated. A further lesson of that epidemic has been that many tests hitherto relied on to demonstrate the presence of arsenic have really been equally ready to respond to the presence of selenium or even of antimony.

These preliminary remarks are intended as an apology for attempting to show that persons who work with compounds of antimony, and, most notably, persons who handle type containing it, are subject to a species of chronic antimonial poisoning, which manifests itself chiefly as a neuritis, allied to arsenical neuritis, and which is essentially distinct from lead poisoning, to which they are notoriously subject.

The symptoms appear to be such as to make it seem that if any considerable number of printers do suffer from chronic antimonial poisoning, attention would certainly have been drawn to it already. I happen to live in a part of Dublin which is the centre of the printing industry, and have had a series of compositors and others coming to me with affections characterised by the ordinary symptoms of peripheral neuritis, accompanied by marked affections of the bladder and prostate, acute headache, abdominal tenderness, dry, glazed, and irritated conditions of the gums, tongue, throat, and digestive tract, as well as a characteristic and intense depression, at times bordering on a suicidal tendency, which, generally speaking, this is the first time that they seemed to me to be evidently due to the absorption of antimony during the course of their work.

Sir P. Manson, it will be remembered, stated that a similar neuritis is often occasioned in the orient, because of the ingestion of tin compounds. Some thirty years ago Dr. Smith was appointed by the Home Office to investigate and report on the health of printers in London. He describes them as we know them now, mostly pale, thin, nervous, and anxious-looking, with large and prominent eyes, often myopic, having a chronically tired air, almost invariably with decayed and defective teeth, and often victims of external and internal affections. The usual sufferer tends to liver troubles and piles, and almost always dyspepsia, though not unfrequently with fair, but dainty appetites. They are often subject to colicky attacks and other indications of lead poisoning; generally with long and clubbed fingers, peculiarly irritable, and often morose and melancholy. Often affected with bladder and prostate troubles, very frequently of alcoholic habits; usually a short-lived race, and prone to die of paralytic affections.

The general tendency has been to attribute the affections of printers largely to their night work, to the usually ill-ventilated character of printing offices, to the peculiar modes of living, and most of all to their alcoholic proclivities.

It is precisely this last factor which has been made the scapegoat for very many affections which would otherwise have demanded strict scientific investigation, in order to discover their exact etiology. Obviously the proprietor of a printing office is more prone to suppose that any symptoms of nerve trouble which his employees may exhibit are rather due to the indulgence in intoxicants than to the results of working in a tainted atmosphere. And I fear we medical practitioners are rather inclined to class every neuritis as probably due to alcohol, and so often fail to trace its real cause. I believe that, taken in the aggregate, the symptoms above described are largely due to antimonial poisoning.

Antimony being unquestionably present in type along with lead, there appears at once an a priori reason why those who handle it should be liable to antimonial poisoning. But, according to my observations, it seems more prevalent of late years, when the actual handling of type is not so common, on account of linotype machines and other contrivances.

Many have questioned whether it is possible to absorb any notable quantity through the skin, although it is notorious that tartar emetic, when employed in the form of an ointment, at once provokes a reaction and brings about a typical putrid eruption.

Van Hassler, indeed, states that chronic antimonial poisoning is common among those working with that metal, but it rather seems to me that the cases which now occur in printing offices are mostly due to antimony without antimoniated hydrogen. This gas is an active poison, and more readily evolved from alloys, like printers' type, than from the pure metal. It is readily disengaged by the action of sulphuric or hydrochloric acids, which are now often used in printing establishments for etching purposes, and most readily of all by nascent hydrogen, which is now of common use by all building. Whether accumulators for the storage of electrical energy are used. Hydrogen is, indeed, commonly found about any electrical apparatus, and hence it seems that the production of antimoniated hydrogen must be common in places where antimony is employed than it was before the introduction of electric light.

Besides the ordinary symptoms of neuritis and the mental depression in cases of apparent antimonial poisoning which have come under my notice, some have been marked by feebie action of the heart. This is to be expected, as antimony is known to be a powerful cardiac poison. The liver appeared enlarged, and that antimony has a specific action in inducing enlarged liver in geese and fowls has long been known to fowl farmers, who put grey antimony into the drinking water of geese. An obvious difficulty in the diagnosis of antimonial poisoning is the differentiation from lead poisoning, the same liver, as the same patient may have both affections.

In the former disease there is not quite the same cachexia nor the same wasting of the muscles; the abdomen is more tender, and the blue line in the gums is absent, although the gums may be tender and red and the teeth loose. The small muscles of the hand are not generally affected in antimony poisoning, whilst they are, of course, usually in saturnism.

Sensory disturbances are commoner in the former, reaction of degeneration in the latter.

Colic is seldom found in antimony poisoning, though the abdomen may be tender and tender.

To distinguish from arsenical neuritis one must rely largely on the history of the case, but it is seldom so painful as arsenical neuritis, neither is there the glossy skin, the pigmentation, or the herpetic eruptions. The comparatively chronic course also tends to differentiate it. From alcoholic neuritis the distinction is not always plain, but one finds a neuritis in total abstainers, and like antimonial neuritis generally it is accompanied by a general feeling and air of melancholia and depression, which contrasts it strongly from the exuberant optimism of the mere alcoholic.

It would be improper to enter minutely into the pathology or treatment of the disease before this Section, which is rather concerned with the prevention of disease.

As regards the therapeutics, cases seem to improve under the usual nerve tonics, such as phosphorus, nux vomica, and quinine, with fresh milk and fresh vegetables, where the patients were removed for a time from their printing office.

The question of prevention obviously turns on the sufficiency of the air supply, the proper ventilation of the rooms, the limitation of the number of hours spent therein, the avoidance of the presence of electrical generators or accumulators near the printing office, and the type is stored or handled together with the usual precautions recommended in cases where lead poisoning is liable to occur. If the existence of antimonial poisoning as a common affection among printers be admitted, local sanitary authorities will doubtless endeavour their medical officers with sufficient power to deal with it from the prevention point of view.

An action was tried last week at the Manchester Assizes in which Dr. Blacklock sought to recover a sum of money due in respect of the purchase of a partnership practice, payment of which was based on the ground of misrepresentation as to the value of the practice sold. Without waiting to hear all the evidence the jury found in favour of the plaintiff and against the counter claim for damages.
TUBERCULOUS MENINGITIS
IN INFANTS AND CHILDREN:
WITH NOTES OF TWO CASES.

By JAMES BURNET, M.A., M.B., M.R.C.P.Edin.;
Clinical Tutor, Extramural Medical Ward, and formerly Resident
Physician, Royal Infirmary, Edinburgh.

There is perhaps no disease of infancy and childhood so insidious in its onset as tuberculous meningitis. At first the child is merely "out of sorts." On the one hand it may be irritable and peevish, while on the other it may be listless and apathetic. The characteristic initial symptom is, in my opinion, a marked change in the child's temperament. A formerly good-tempered child will become cross and fretful; a bright, active one will show disinclination for play, and, instead of romping about as formerly, will sit quite still in a moody fashion. Another early symptom I have often observed is sighing. The child takes a long, deep, audible inspiration, often accompanied by yawning. Still a third condition which is seen at the very onset of this disease is conjunctivitis. These three phenomena, change in temperament, sighing respiration and conjunctivitis, are, in my opinion, some of the most commonly observed initial signs of this disease. In the early symptoms often resemble most closely those produced by intestinal parasites, or by digestive disorders; and it is only by the most careful observation that we are able to arrive at a correct diagnosis of the condition present.

The following case illustrates some of these points very clearly:—Helen C., ast. 3. Previous to the onset of her illness she was an exceptionally bright and intelligent child. In the beginning of the year she was noticed to be less active than usual, and inclined to sleep during the day. She also began to show a marked disinclination for food. She had no pain, and her parents thought the child was suffering from influenza, which was very prevalent at the time. Some weeks later I was asked to see her, as she had "sore eyes." I found the child suffering from conjunctivitis, and on elevating the right lower lid an oval-shaped inflammatory swelling was seen occupying the central portion. The eyes were treated with lotio. acid. borici and ung. hydrarg. oxid. flav. In the beginning of February they were better. On the 14th of that month, as the child's tongue was coated and the bowels were not acting at all regularly, I ordered a mixture containing sod. bicarb., tinct. rhei., and gentian to be taken before meals. In a few days the tongue was cleaner, and the appetite somewhat improved. The child, however, was still drowsy, and I noticed that she was frequently sighing. My suspicions were aroused as to the possibility of tuberculous meningitis. On the 20th I was asked to call at once as she was "in a high fever." I then found the child perspiring freely, and the axillary temperature 103° F. She had a very listless expression. I questioned the parents closely, but could elicit nothing beyond the fact that the child was often restless during the night, and occasionally would start up screaming. I ordered the child to bed, and at my evening visit the thermometer registered 101° F. Next morning I found the temperature had fallen to 100° F. As the parents had all along maintained that the child suffered from worms, I ordered a dose of antonin, but though the bowels were freely moved no worms made their appearance. By this time I had made up my mind that the case was one of tuberculous meningitis.

After this the bowels became very constipated, and the child more listless and apathetic. On the 21st I examined the eyes ophthalmoscopically, and the result was entirely negative. On the 24th the child lay perfectly still in bed, and made no reply to questions. She seemed very emotional, however, and kept constantly crying out as if in pain, or as if she wished for something she had not got. Her mother had bought her a doll, but, though the child was exceptionally fond of dolls, she took no notice whatever of it. Appetite was almost entirely gone, the only article of food she cared to take being boiled. The thirst was extreme, and the tongue was now raw and sore. The lips were also dry and cracked. The pulse was 120. Breathing was normal, but a few crepitations were audible over both lungs behind, and the patient had a short, dry cough.

On the 25th the temperature rose to 102½° F. In the morning it was noticed that she kept putting her left hand up to her head, but on percussion over the scalp there seemed to be no pain. On the 27th I received an urgent message about 7 a.m.. On my arrival I found the temperature to be 104° F. The cheeks were somewhat flushed, and the skin dry and hot. The hands twitched convulsively and the mouth also, which was drawn spasmodically towards the right side. There was no actual paralysis. On inquiry, I learned that the child had been very restless during the night and crying out. While I was present she screamed repeatedly, the sound resembling very closely the cry of a cat in distress. As the temperature was elevated, ice was applied to the head. At 10 a.m. the patient was quieter. The face, including the chin and both cheeks, was scarlet, so that the child looked exactly like a case of scarlet fever. The body was wet with perspiration. She had passed neither urine nor feces since the previous evening, and that afternoon she was somewhat board-like. At 7 p.m. the temperature had fallen to 102° F. She was now passing both urine and FECES in bed, and the abdomen had become perfectly soft. The face was now pale, save for the flushed spots on either cheek. I gave a very grave prognosis, and fully expected death to supervene before the end of the next twenty-four hours.

From this time the child gradually sank, and from time to time twitchings were observed in the arms and hands. The palms were kept constantly clenched, with the thumbs turned inwards, while the condition known as drop-foot was well marked on both sides. The body as a whole was somewhat rigid. The breath also became clenched, so that the mouth could only be opened with difficulty. Sordes collected about the lips and teeth. This was her condition on March 2nd. On the 3rd I saw her at 11 a.m. The temperature was then 103½° F. The body was greatly emaciated. The hands were blue and cold, and the radial pulse could not be felt on either side. The feet and legs were also cold. She died quietly at 2 p.m.

The temperature chart in this case was of interest as showing a definite rise of temperature exactly a week after the first onset of fever. I would also
I think this case is of some interest on account of the almost maniacal excitement which was exhibited by the patient. As regards the predisposing causes of tuberculous meningitis, I think impure air and improper feeding are important. Very often the child has been kept shut up indoors, all the windows being closed, with the room full of dust. The result of this is that the tubercle bacillus finds an entrance to the weakened tissues, it may be by way of the nose, eye or ear. The prognosis of this disease is not good; in fact, it is as bad as it can possibly be. Cases have been recorded of so-called cures; but these cannot possibly have been genuine. Written on the morbid conditions present, we see at once the hopelessness of such cases. Cure being impossible, treatment need hardly be attempted. Still, we must do something. We must support the patient's strength by well-regulated nourishment and suitable medicines. Ice is very often applied to the head in these cases, but it must be used with great caution lest delirium and collapse. In cases where the anterior fontanelle is depressed an ice-cap is a danger to be carefully guarded against.

**Clinical Records**

**CASE OF MEDIASTINAL LYMPHADENOMA.**

By Dr. H. LE ROUX,

The other day I admitted an infant who died a few days afterwards of acute apnoea. The autopsy revealed a lymphadenoma of the mediastinum, arising from the thymus gland, which had caused a flattening of the trachea to the extent of giving it a knife-blade shape. The remarkable feature of the case was the short interval of time between the initial suffocative attack and that which determined death. The infant was reported to have coughed a little for a few days, but did not appear ill, when, on the Saturday, it was seized with a violent fit of coughing and complained of a sensation of suffocation that lasted for fully half an hour. Twice after the same day coughing attacks recurred, when the little patient was brought to hospital by the nurse. It remained free from the cough and the sense of suffocation on the way here, but on the following Monday there was a certain amount of dyspnea, slight thyroid enlargement, some distention of the veins of the neck, and an increased fulness of the supra-ternal region. The right subclavicular region was flattened, and percussion elicited dulness. The heart and the large vessels were normal.

I diagnosed tracheo-bronchial adenopathy. My colleague, M. Chatelier, made a laryngoscopic examination, and, finding nothing abnormal, diagnosed mediastinal pressure from thymus enlargement. On Tuesday a slight suffocative attack occurred. On Wednesday two similar attacks came on, and during the night an attack occurred during which the infant succumbed, in spite of all that could be done.

**A Medical Officer of Health Mutked in Damages.**

An interesting case was tried in the Alfreton County Court last week in which it was alleged that the medical officer of health had exceeded the powers of his office by closing a house to be closed for fourteen days in consequence of the occurrence of a case of small-pox therein. It was urged that no such power was conferred by the by-laws, the officer's authority extending only to part of the house. On behalf of the medical officer of health it was denied that he had given the order which was impugned, but the judge awarded the damages claimed (£20), execution to be stayed for twenty-one days.

BRITISH SANATORIA FOR CONSUMPTION.—V.

[NORTH OF ENGLAND SANATORIUM, ANGLESEY.]  
NORDRACH-ON-DEE SANATORIUM, BANCHORY, N.B.

Deeside has long been famous as a health resort. It was selected by the Royal Commission of 1871 as the most suitable district in Scotland for a Royal Retreat, and here, as everyone knows, Balmoral Castle proved a favourite home of our late Queen. Nordrach-on-Dee Sanatorium is delightfully situated in middle Deeside. It is a little to the west of Banchory, and a little over four and a half miles from Aberdeen. Opened in 1900, it offers exceptional advantages for the most complete application of the hygienic treatment of consumption. The site is probably the best for Scotland for the purpose. The sanatorium has been erected in the midst of a pine forest. On the north it is protected by hills rising in one part to 1,545 ft., on the south lies Goich Hill, of 1,104 ft., and away to the west stand the peaks of the Grampians. The climatic conditions also appear to be particularly suitable for phthisical cases. The rainfall is low, being only 28 ins.; the temperature of the air in the winter months is relatively high, while in summer it is cool and bracing: the percentage of ozone is high; much sunshine is enjoyed, and south or south-west winds prevail during nearly nine months of the year and are comparatively warm. The soil is red gravel and contains much alumina, and is particularly absorbent, and even after heavy rain the surface readily dries. The moisture quickly finds its way into the fast-flowing Dee. The glorious outlook is calculated to have a good psychological effect on the patients. The sanatorium has been admirably designed and excellently constructed. There are three floors, and in the centre there is a high tower. The building is only one room and corridor deep. The ground-floor contains rooms for the medical and nursing staff, a large drawing-room for use in inclement weather, and a library and writing room. There is a glass-covered verandah, but this is not used as a "liegehalle." Recently the institution has been considerably extended, the newer bedrooms being provided with excellent balconies, which, however, are so constructed as to offer but little impediment to light and air.

The bedrooms are of an excellent type. The windows occupy two-thirds of the outside wall-space, and are provided with louvre shutters; the walls are attractively pointed; all corners are rounded; and the floors are of polished wood. Fanlights are situated over the doors. As a protection from fire and damp, silica wool has been inserted in each wall. Every bedroom is furnished with a douche bath and two fitted-in basins and provided with hot and cold water. Heating is by steam pipes and the lighting is electric. Communications are maintained by an excellent system of electric bells. The dining-room is placed separately: it is a particularly spacious and peculiarly attractive room, 56 ft. long and 24 ft. wide, with large windows on three sides. The kitchen and servants’ accommodation constitute a separate block. The engine block stands at a distance of over 100 yards from the sanatorium, and is hidden by densely wooded ground.

The lavatories, water-closets, and bath-rooms are placed in separate blocks entered from the main corridor. The water system of sanitation is elaborate, but apparently very effective. The water supply is excellent.

The system of treatment followed appears to be designed on the best and most effective hygienic methods. The element of personal supervision is well maintained. Members of the medical staff live in the sanatorium, dine with, and share the general life of, the patients. Much attention is devoted to the dietetic aspects of the management of the cases. The grounds are particularly suited for an efficient conduct of graduated exercises. There are many miles of walks within the sanatorium grounds, and patients may extend their wanderings far into the adjacent pine forests. Many of the paths are suitably marked by distinctive colours. A number of excellent and picturesque shelters are scattered about the grounds.

Everywhere there is evidence of a scientific precision in the direction and general conduct of the institution. The notes of cases are well kept. A special report is sent to the private medical attendant of each patient every month. Special charts, several showing considerable ingenuity in design, are used. There is a well-equipped laboratory. Well furnished rooms also exist for throat work, radiography, the use of electricity, high frequency currents, and ultra-violet light. There is also a well-appointed dental room.

Convenient elevators are provided for the use of the patients.

Altogether, Nordrach-on-Dee deserves to rank high as an excellent private sanatorium for the well-to-do class.

The resident medical staff consists of three physicians. Dr. David Lawson, the founder, still acts as senior physician, and directs the work of the institution. Dr. J. McKenzie Booth, of Aberdeen, attends as consulting laryngologist; and Mr. T. Alexander Macintosh is consulting dentist.

Patients of either sex are admitted.

The terms are five guineas weekly. This charge is inclusive, the only extras being personal laundry and alcohol; but the latter is only allowed when medically prescribed. The sanatorium is on the telephone. It can be readily reached from London by through carriages to Aberdeen, thence to Banchory, where a carriage meets the patient and he is driven a little over two miles to Nordrach-on-Dee.
FRANCE.

[FROM OUR OWN CORRESPONDENT.]

PARIS, July 28th, 1903.

THE DIAGNOSIS OF ULCER OF THE STOMACH.

If the diagnosis of gastric ulcer is relatively easy in the cases where the three fundamental symptoms of this affection (pain, vomiting, and haemorrhage) are present, on the other hand it is far from being so in the absence of one or other of these symptoms. Considered separately, none of the three signs in question present a pathognomonic value, as they are to be met with in many different gastric affections.

According to M. Mendel, there exists a method which facilitates the diagnosis of doubtful cases and renders it possible to control the progress realised by the treatment.

The method in question consists in striking the epigastric region—by the aid of a small hammer, similar to that used in percussion—a series of small taps. No pain or incontinence is felt by the patient if the stomach and the neighbouring organs are healthy. But where an ulcer is present the operator will not be slow to discover a point where the slightest stroke of the hammer produces an intense pain, followed by a painful sensation lasting for some time. By careful research, this sensitive zone can be exactly defined and traced out, and at this spot it may be presumed that the ulcer is situated. If the treatment be appropriate the zone will diminish gradually and finally disappear, indicating that the ulcer is healed.

The same method would be capable of rendering good service in the diagnosis of ulcer of the duodenum, an affection which is still more difficult to recognise than gastric ulcer. The painful zone, of the size of a florin, is situated close to the line alba, a little below the centre of the space comprised between the umbilicus and the costal edge.

PERMANGANATE TREATMENT OF Erysipelas.

The treatment of erysipelas by permanganate of potash is strongly recommended by a professor of one of the hospitals. He proceeds as follows:—A piece of lint, sprinkled with thurine is twisted with a solution of permanganate of potash 1:1,000, and applied to the affected parts. Under the influence of these applications, associated with quinine internally, the malady progresses rapidly towards a cure. Out of 130 cases thus treated only three were attended with complications (endocarditis, phlegmon). All the patients got well and generally in two or three days.

GERMANY.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, July 25th, 1903.

At the German Society for Surgery Dr. Höpfnr reported having made experiments on animals as to TRANSPLANTATION OF VESSELS.

In experimenting on dogs, he took a piece out of the femoral artery and transplanted it into the carotid. With careful and accurate suturing, good union took place with permeability of the transplanted portion. He had also amputated extremities and reunited them with success. He advised the adoption of the procedure with human subjects in suitable cases.

Dr. Heile, Breslau, spoke on the ANTESEPTIC ACTION OF IODOFORM.

He remarked that on account of its prompt action, iodoform had become a standard among clinicians, whilst experiments in the reagent glass only showed that it possessed a very moderate germicide power, in that it scarcely brought about the destruction of micro-organisms. Not being satisfied with this, he set about a new series of experiments. In these he discovered that the bactericidal action of iodoform was only developed by its decomposition, which was set up by the living tissues. He used trituration of liver, mixed staphyloccoci and streptococi with iodoform, and brought the two together. After some days no action worth naming was observed, even when they had been shaken up and air had been introduced. When the process was gone through, however, without air, when the mixture was covered with paraffin, reduction was much more rapid, and in the course of two or three days the destruction of the micro-organisms was complete; but in a mixture without liver tissue there had been but little change. When liver tissue had this power the conclusion was permissible that other animal tissues had a like effect, and, in fact, a similar result was obtained with all the tissues experimented with. Liver showed itself the most active, fat and brain tissues the least, the other tissues occupying an intermediate position. It was the same with iodoform; iodoform was reduced in the tissues and that the amount of bactericidal action was in proportion to the amount of reduction. Water and bouillon produced no reduction; pus caused some, and granulations acted like other tissues. It was not the iodine split from the iodoform that was the active agent, nor was it acetylene; it was rather a fixed body—deiodo-acetylene.

From this it appears that iodoform applied to superficial wounds, therefore, with free admission of air, was not active. It owed its extensive use as a good antiseptic to its favourable action in cavities. Here were found living tissues, with little admission of air, as in intra-peritoneal operations. Whence also the favourable effect of injection of iodoform into tuberculous joints. By comparative experiments with other antiseptics it was shown that iodoform, which was behind them as a bactericide, applied under the condition named was superior to them all—even to sublimate.

Hr. Petersen, Heidelberg, reported his ANATOMICAL AND CLINICAL INVESTIGATIONS INTO CANCER OF THE STOMACH AND INTESTINES.

They had extended over 150 cases of cancer of intestine and 100 of cancer of the stomach. The development of the disease was either multi-central or uni-central. According to his investigations they only developed uni-centrally in lymph tracts. The outer portions of the growth were useless as regarded the study of histogenesis, as they were not developed primarily. This development could not be brought into accord with the parasitic theory. Bowel carcinoma grew more deeply, whilst carcinoma of the stomach spread more laterally and superficially. After extirpation recurrence could only develop from cells previously diseased; another question was whether disease must always return from such diseased cells. One saw everywhere transitions from cancer to normal cells; so also in the stomach. In their margins we saw peculiar cells of which we could not say whether they were carcinomatous or not; whether normal cells were formed from them, or whether they degenerated carcinomatously. In the glands also in carcinoma of the uterus similar cells were seen which were not held to be carcinoma. Such cells, in the speaker's opinion, did not give rise to recurrences, the system, in virtue of its protective power (phagocytosis) might compensate for these diseased cells, so that in all collections met with in extirpation of the disease in the stomach might be left, with safety. The demand

TORTICOLLIS AND NVSTAGMUS.

At the Aereate meeting, Swobada showed a child, aged 22 months, with a severe form of torticollis which relaxed during sleep. At every attempt to correct the deformity of the head nystagmus appeared. At an earlier period in the disease spasmus nutans was excited when correction was attempted.

Reuss said that torticollis appeared to be the compensating factor for nystagmus, as this disease often arises from a prolonged holding of the head in one position, giving a false appearance of movement and giddiness.

URTICARIA PIGMENTOSA CRONICA.

Swobada drew the attention of the members to a case of urticaria pigmentosa chronica. The patient's body was covered with pigmented spots about the size of lentils. There was no itching over these brown spots, which might lead the case to be thought one of syphilis, but against the latter no history, nor trace thereof, could be found. When any part of the body was rubbed large white blisters arose on a red base.

RADIIUM AND MALIGNANT TUMOURS.

Exner brought forward two cases of melanoma-sarcoma of the cutis which he had treated with great success by means of the radium rasp. The first case was one of melanoma-sarcoma of the left arm. The tubercles varied from three to four millimetres to one and a half centimetres in diameter. The duration of each sitting was from five to fifteen minutes, and was continued for fourteen days. All the small tubercles had quite disappeared, while traces of the large ones were yet to be seen.

The second case was that of a patient, aged 61. This had proved refractory, the disease having recurred several times in the squamous epithelium over the tumour, which lay in the floor of the mouth. By persevering with the radium rays the ulcerating tumour has since taken on a healthy appearance, while the swelling is receding.

RADII MELLIAE RONTGEN RAYS.

The radium rays seem to meet with a considerable amount of success in the hands of all who have tried it, yet from all the testimony to hand it is very difficult to estimate its real value.

Holzmecht brought forward a variety of cases to show the relative value of the two kinds of rays. The first was a case of psoriasis vulgaris, which required two hours' treatment with the Rontgen rays, but the same effect could be produced in one minute by the use of the radium rays, the plague disappearing in an incredibly short time. The second case was one of lupus tumidus, where both kinds of rays were used with complete resolution. Holzmecht remarked that the Rontgen rays only improved these cases, which required the Finsen rays to bring about complete resolution. The third case he exhibited was that of a man who had suffered from an epithelioma of the cheek, which had now quite disappeared. The rays of radium were only used three times in this case, with five minutes' application at a time. The fourth case was of telangiectasis of the right arm. In the diffuse red part the radium capsule was applied in the form of eight points for ten minutes. Shortly after the conditions began to return from these eight centres, leaving in the end a soft white skin. These facts, he thought, went to confirm Niesser's teaching that the rays of radium enhanced the activity of the intima of the capillaries, while the "pre-capillary" vessels degenerated, and finally were obliterated by the action of the light.

LUPUS, OR BLASTOMYCOSIS.

Brandweiner next exhibited an interesting case, that of a person, aged 37, who first came to him with a lupoid condition of the left side of the nose, which was red, infiltrated and soft, with acne-looking tubercles which discharged a light yellow viscid pus from their centre. From the breaking down of these nodules, ulcers with irregular cleft papillae formed at their bases. These finally healed, leaving soft irregular scars without any pigmentation.

Microscopic examination of the pustular contents revealed a genus of torula resembling a yeast cell, four to ten millimetres in size, and having a double contour in formation and structure. He thought this was a case of blastomycosis, described by some American authors as a distinct disease.

Kren demonstrated another patient, aged 37, with the same affection.

This coincidence caused Oppenheim to state in answer that he had seen three such cases in Vienna very recently, which yielded satisfactorily to full doses of iodide of potassium. He understood there were now forty-five of these so-called blastomycetes on record with five deaths, in whom the disease is reported to have been general. He thought the affection required more attention.

Lowenbach referred to the histological points of the disease, and said that there was a great similarity between lupus and tuberculosis verrucosa cutis, but by Gram's method of colouring it was very easy to distinguish between either of these and the blastomycetes. All the ultra-violet rays. All the ultra-violet rays.

CATALYTIC FUNCTION OF HUMAN MILK.

Hecht and Friedjung described a test they had performed to prove the catalytic quality of human milk, which comprises a number of super-oxidised hydrates which are fermenters that rapidly break up the nutritive constituents of the fluid. They showed by example how this fermentative action could be meas-
sured by taking the carbonic acid product in a modified fermenting saccharometer. They further demonstrated how to estimate the nutritive value of a milk as it entirely depended upon this property of fermentation.

**ENURESIS AND INJECTIONS.**

Kapsamer discussed the subject of enuresis and the treatment adopted by Catleine some time ago, which was the use of a cocaine solution as a subcutaneous injection into the sacral canal.

He, Kapsamer, had now treated twenty-five cases of enuresis in this way with remarkable success. He added that he had somewhat departed from Catleine's solution, and used the physiological salt solution in thirteen of the cases with the same result as if injecting cocaine. One of these cases was treated a year since. The cure was effected with the salt injections, while eight others were treated more than six months ago. In all the cases he had not seen an accident of any kind from the injections, except one where the nerve eripites seemed to suffer from shock.

**The Operating Theatres.**

**GUY'S HOSPITAL.**

**OPERATION FOR CHRONIC OBSTRUCTION PRODUCED BY CONSTIPATION.**—Mr. Arbuthnot Lane operated on a woman, aged 22, who had suffered from constipation all her life, and for some time had recurring attacks of pain in the right iliac fossa and loin. These had been regarded as appendiceal in origin. When the patient was seen for the first time by him about three years ago, the cæcum was found to be dilated and hypertrophied, and the woman complained of pain in the right iliac fossa and lumbar region, with considerable tenderness on pressure over the cæcum and ascending colon in front and behind below the last rib. The appendix could be felt, but it was impossible to differentiate its tenderness from that of the cæcum, beneath which it lay exterally. The symptoms were all exaggerated when the patient had been standing about for some time; a varying amount of relief was obtained when she assumed the recumbent posture. Mr. Lane said he regarded the case as one of chronic constipation, which had produced a distension of the cæcum or the cæccop of the gastro-intestinal tract. This had produced a dilatation and hypertrophy of the cæcum and ascending colon with the formation of abundant adhesions between it and the abdominal wall externally. These adhesions, he pointed out, had, after a time, developed into a mesentery, which exerted upon the hepatic flexure such a traction as to render it sufficiently kinked to produce a varying amount of obstruction. This condition, Mr. Lane said, he had already described very fully in his writings; it was very commonly met with, and its symptoms are usually attributed to disease of the appendix, which may or may not be a complication of it. The patient was feeble and emaciated, and presented the subjective and objective symptoms which are associated with very severe constipation. Her abdomen was opened, and the conditions Mr. Lane had described were found existing in a very marked degree. The appendix was bound down by the adhesions, which had attached the cæcum and ascending colon to the abdominal wall, but its lumen was not materially affected by them. It is usually, he pointed out, by the kinking up of the appendix caused by these adhesions, which result directly from an imperfect drainage of the cæccop, that the lumen of the appendix is permanently or temporarily constricted, and the condition called appendicitis results. The appendix was removed, and the cæcum and colon both freed from the disability which resulted from the adhesions. It was noticed at the time that the intestines were remarkably inactive, the coils assuming and retaining any shape impressed on them by the fingers for a very abnormal length of time. The abdomen was closed and Mr. Lane said that the patient would be given a purge on the following day, and this would be repeated at frequent intervals with the object of preventing the formation of adhesions.

It is interesting to note that this treatment was most satisfactory in its results. It was supplemented by abdominal massage. After some months, however, the constipation returned, and it was with the greatest difficulty and only at long intervals that the patient could obtain any evacuation of her bowels. She was again operated on, when it was found that the adhesions had re-formed as before. More stringent methods were adopted, with the same success; but again the condition recurred, and again she derived temporary benefit from the same operation. After a much longer interval she was readmitted into the hospital, and after again freeing the bowel she was turned on to her left side with the object of attaching the bowel to the abdominal wall in front, and she has been kept in this position since. Should he not succeed in relieving the recurrence of the obstruction by this means, Mr. Lane proposes on the next occasion to open the ileum into the sigmod, and so throw the remainder of the large bowel out of use.

**KING'S COLLEGE HOSPITAL.**

**OPERATION FOR OLD DISLOCATION OF THE SHOULDER.**—Mr. Peyton Omlar operated on a man, aged 50, who had a dislocation forwards of the head of his right humerus of six months' duration, together with intense pain in the right arm. The joint was ankylosed, the arm hung in a very awkward position and was quite useless. The patient was not a good subject for operation, but it was thought that some improvement, at any rate, might be effected by operation. The man having been in the usual recumbent posture, an incision was made over the joint, starting from the tip of the acromion and extending downwards for five inches. After separating the muscles, which were matted together, as was also the tendon of the biceps, it was found that the original dislocation had been accompanied by a fracture of the neck of the humerus. The glenoid cavity was found to be perfectly normal, but there was so much new bone and fibrous tissue about the head of the humerus that it was quite impossible to place it in position, so it was removed at the seat of the old fracture. When this had been done the upper end of the shaft of the humerus rested just below the glenoid cavity. The large wound was then stuffed with gauze, the skin edges being approximated by sutures for about three inches, and Mr. Beale said that the case would be a long one, for the patient was an old soldier who had suffered from syphilis badly, and was generally not a good subject for any extensive operation. He expected some necrosis at the top of the divided humerus, and therefore stuffed the wound. As a general rule it was not advisable, he thought, to undertake an operation of this kind in a patient over forty-five, but in this particular case it seemed justifiable, as the dislocation was of less than a year's duration. There was complete fixation of the joint, indicating some further injury than a simple dislocation, and there was very considerable pain down the arm.

WEDNESDAY, JULY 29, 1903.

BOVINE AND HUMAN TUBERCULOSIS.

The views of Professor Koch as to the essential difference between the bacillus of human and of bovine tuberculosis have not been confirmed by subsequent investigators. They possessed a practical bearing of almost incalculable effect upon the preventive hygiene of the community as regards the scourge of phthisis. Many authorities hold that the malady in mankind is largely due to the ingestion of the products of bovine tuberculosis. If Professor Koch's startling thesis be true, the transmission of the tubercle bacillus from man to the lower animals and vice versa must be regarded as a remote, if not an altogether impossible, contingency. Needless to remark, any such proposition announced by so distinguished a scientific authority as the discoverer of the tubercle bacillus would be criticised by the medical world generally in a spirit of the utmost caution and moderation. The matter has now been examined and reported upon in various authoritative quarters. In Germany itself the verdict has not been favourable to Professor Koch's views. In the United Kingdom various distinguished experimenters have accepted the identity of human and bovine tuberculosis in a clear and unqualified manner. Indeed, recent experiments have assumed the power of transmissibility of comparative tuberculosis as an established fact. A most interesting set of investigations, for instance, has been conducted at the Jenner Institute by Drs. Dean and Todd, at the suggestion of Lord Lister. Their object was to ascertain whether the tubercle bacillus of human origin undergoes any marked change in virulence towards the bovine species by passage through certain other animals. The material used was sputum from cases of well-marked pulmonary tuberculosis in man, and the animals experimented upon were the pig, cat, rabbit, rat and mouse. For the most part the results of these experiments were negative, but in the case of the pig some most interesting and valuable observations were made. Pigs inoculated with human tuberculous sputum became infected with tuberculosis. This fact is crucial as regards the theory of Professor Koch, inasmuch as his views were largely based upon the experimental inoculation of lower animals. Two pigs inoculated by him with pure cultures failed to develop the infection. It is suggested by Drs. Dean and Todd that this difference in results is that the greater infective power of sputum over pure culture may be due to various factors—for example, (1) "in the sputum the bacillus probably retains its original virulence, and has undergone no modification, as may be the case in cultivation; (2) the associated organisms or their products in the sputum may assist in the process of infection." The feeding of pigs produced results not less striking than those obtained by inoculation. Professor Koch obtained some form of infection in three out of six pigs thus treated. Drs. Dean and Todd, on the other hand, used three pigs, all of which contracted a local but definite infection, followed by great wasting and death. They state that the tuberculous lesions appeared hardly sufficient to account for death or for the emaciation, but point out that the animals were somewhat younger than those employed by Professor Koch, and that the feeding was commenced at the period of weaning, when young animals are liable to catarrhal intestinal disturbances. These investigations appear to disclose an initial fallacy in Professor Koch's chain of reasoning. In any case, they form a brilliant contribution towards the better understanding of a problem that is being slowly but surely unravelled by the labours of modern science. The Jenner Institute may be congratulated on the zeal and ardour of the distinguished band of workers that have found encouragement and shelter within its portals.

THE TRYPANOSOMA CASTELLANII.

With the steady advance of scientific medicine, hidden things are being one by one gradually brought to light. Each fresh discovery marks another milestone upon the onward journey of medical research, which leads ever upward towards the elucidation of those problems which at times seem as if they were incapable of any solution. The science of bacteriology has revealed and made clear many things which we should never have been able to ascertain without its aid. Our list of acute specific infectious diseases due to a "cause unknown" is becoming smaller and smaller, and the time cannot be far distant when a distinct and definite cause shall have been assigned to every acute malady with which we are acquainted. The etiology of that obscure tropical disease known as "sleeping sickness" has long baffled the many attempts at explanation on the part of skilled and painstaking observers in the past, who have, at times, been very near the light, and yet have been reluctantly
compelled to acknowledge that their efforts were devoid of any constant or satisfactory result. It is with special interest, therefore, that we turn to the recent work of Dr. Aldo Castellani, who has laboured in this field for the last year in connection with his office as bacteriologist to the Royal Society Commission for the investigation into the etiology of sleeping sickness. In a paper embodying the result of his researches, published in the Journal of Tropical Medicine, Dr. Castellani reviews the previous work of Le Dantec, Ferguson and Manson. The views of the latter observer, who suggested that the *Filaria persians* was the probable cause of the malady, are the most familiar to medical men, and up till now this theory has held the day. Other writers, among whom are Cagigal and Lepierre, Marchoux, and Dr. Broden, have ascribed the cause of the disease to various bacilli. A special form of streptococcus has been found in several cases by Dr. Castellani, but it was not until November, 1902, that he began to observe the frequent presence of a trypanosome in the fluid obtained by lumbar puncture, the technique for which procedure he greatly improved. In 70 per cent. of cases of sleeping sickness this organism was found in the cerebro-spinal fluid. The parasite does not appear to be precisely identical with the Trypanosoma Gambiense, described by Dutton and Forde as occurring in relation to trypanosomiasis, which is a specific febrile disease affecting Europeans in the tropics. Moreover, this variety has only been found in the blood. The trypanosome discovered by Dr. Castellani has also been found in the blood, together with other special bodies, which are considered to be developmental stages of the parasite. A series of control experiments was also undertaken, with the result that the organism was never found in the cerebro-spinal fluid in other diseases. With regard to the difference between the two varieties now known to occur in the human subject, we may quote Dr. Castellani's own words: "I do not see any reason why man should not be attacked by different species of trypanosomes, each of which might give rise to different diseases. This fact has been clearly demonstrated in the lower animals. The horse, for instance, is liable to be infected by three different species of trypanosome; *Trypanosoma Bruci*, the cause of nagana; *T. Evansi*, the cause of surra; *T. equiperdum* (Döfflein), the cause of the disease called 'dourine.'" These are very important and suggestive remarks, and it is not impossible that further research upon these lines will be productive of more confirmatory evidences of the truths contained therein. In the later stages of the malady, Dr. Castellani is inclined to believe that there is a concomitant streptococcal infection, which, although playing an important rôle, is not the primary cause of the trouble. There are many diseases in which secondary infections by other organisms than the primary one occur, as, for example, in diphtheria. But it is the *Trypanosoma Castellani*, the name given to the parasite by Kruse, of Bonn, in honour of the discoverer, that we must now look upon as being in all probability the specific cause of this hitherto mysterious complaint. It is to be hoped that Dr. Castellani will be enabled to clinch his discovery by the application of inoculation tests, and that a rational basis will be established for the treatment of the disease.

PROPOSED GOVERNMENT VACCINE ESTABLISHMENT FOR SCOTLAND.

A DEPUTATION of Scottish medical men and members of Parliament waited on Lord Bal-our of Burleigh on July 15th for the purpose of supporting a memorial in favour of a Government vaccine establishment for Scotland. The memorial was prepared as the result of a conference of the various medical bodies in Scotland, and set forth that while the greatly preferable vaccination with calf lymph is superseding arm to arm vaccination the only calf lymph available in Scotland is that obtained from private manufacturers, and not, therefore, subject to any such inspection as can guarantee its purity and efficiency. In England satisfactory and guaranteed lymph is gratuitously supplied for vaccination, and the memorialists think that this inequality of treatment of the two countries should be removed by establishing a vaccine establishment for Scotland from which lymph could be gratuitously supplied to medical practitioners under such rules as may be considered necessary, and to local authorities during outbreaks of small-pox. The establishment should be able to supply 500,000 tubes of lymph annually, the probable expense being £5,500, or, in epidemic years, £5,000. In support of the views urged in the memorial, the extensive use of calf lymph and the inconstancy of the supply of commercial lymph are put forward, as well as the inadvisability of the lymph supply of the country not being liable to state control. It is probably not feasible to utilise the existing Government institute, since money voted to supply lymph to English public vaccinators could not be devoted to Scotland, with a separate Poor-law and public health system of its own. There is reason to believe that there is a great deal of imperfect vaccination in Scotland, due largely to the uncertainty of the present commercial lymph; and, as revaccination is increasingly practised, and may soon become almost as universal as primary vaccination, there is urgent need of an abundant supply of reliable lymph for both purposes. Sir Thomas Fraser, the leading speaker in favour of the memorial, and Dr. Farquharson urged the necessity of providing efficient lymph for Scotch vaccination, the former pointing out that in England two-thirds of the vaccination was done by public vaccinators with guaranteed lymph, while in Scotland only about 2 per cent. of the vaccinations were done by the parochial medical officers, who were supplied by the Scottish vaccine institution, the latter suggesting that the employment of badly prepared lymph was the most likely means of leading to anti-vaccination agitation. Bailie Graham, Glas-
Notes on Current Topics.

Gout Among the Poor.

To the public mind the connection between gout and high living is so intimate as to be almost proverbial. A certain class of people feel even flattered when informed by their physician that they have a tendency towards gout. Nevertheless, the lithiatic diathesis is by no means confined to the wealthy and leisured classes, as is shown by Dr. F. S. Toogood, in the Practitioner. Occupation does not appear to influence the incidence of gout, or only to a slight extent, but certain actions of the body, as much walking, the constrained position of the wrists in holding reins, and the grip of the iron by laundry-workers, are conducive to the gouty inflammation of the neighbouring articulations. The general history of the majority of the cases reveals the fact that the consumption of malt-liquor is the most important, if not the sole, determining cause of the production of gout. Men are therefore affected to a greater degree than women, in the proportion of twenty to one. Chronic gout, which clinically bears much resemblance to chronic osteo-arthritis, is very common among the poor, as are also the so-called "irregular" manifestations, such as chronic bronchitis, eczema, and phlebitis. The smaller joints, especially those of the extremities, are chiefly affected by gouty deposits, leading to considerable crippling. Many of the older patients are thus seriously handicapped in their struggle to obtain a living, the finer movements required in cobbling or sewing being rendered very difficult to perform. Highly seasoned food is not by the very nature of things an important factor in the development of the disease among the poor, but Dr. Toogood points out that gout in non-beer-drinkers, even when considerable amounts of animal food are consumed, is rarely seen.

The Value of Strong Abdominal Muscles.

The inequality which nearly always exists between the development of the muscles of the trunk and those of the limbs, even in individuals who profess to be athletic, is one which somehow fails to strike the average anatomical critic. So long as the calf-muscles are firm and prominent, and the biceps and triceps show evidence of good "form," their possessor is classed as muscularly well-built, even though his external abdominal obliques are rarely wanting in sturdiness. The muscles of the abdomen, with their powerful fascial connections, are functionally of great importance, for not only do they afford protection to the underlying viscera by their contraction and resistance, but they have also no small part to play in the mechanics of the circulation. An important article on the subject by Dr. A. P. Beddard appeared in "Guy's Hospital Reports," vol. lvii., in which it is shown that a chronic failure of the cerebral circulation may result from persistent weakness and atony of the abdominal muscles. The syncope not infrequently seen after tapping the abdomen for ascites is due
to the inability of the muscles to contract properly, and the consequent over-filling of the great abdominal veins. Another result of this inefficiency is the gradual production of the condition known as general enteropontosis. The necessity of exercising the abdominal muscles, especially in the debility accompanying certain chronic diseases, was strongly urged by Dr. Alexander McPhedran, of Toronto, in a paper read at the Ontario Medical Association. Such out-door sports and pastimes as rowing, horseback, bowls and golf are invaluable as means of developing the trunk muscles. Massage of the abdomen, judiciously employed, is also useful in conditions of gastric dilatation, splanchnptosis and in some cases of neurasthenia.

Renal Fat Necrosis.
The phenomenon of fat necrosis has long been observed in the various tissues of the body, notably in the subperitoneal fat and in the pancreas. Perhaps it is most frequently seen in connection with acute pancreatitis, but it is known to occur apart from any affection of the pancreas. The fatty degeneration of the cell, which is supposed to be the initial morbid change, passes on into actual necrosis. Dr. James Guthrie, of Iowa University, records the case of a young woman, aged 22, who suffered from a left renal tumour. This was operated upon, and it was then found that the kidney gave way upon its capsule being grasped with forceps, and discharged a fluid resembling in colour an emulsion of cod-liver oil and iodine, containing a peculiar flaky or shredded material. On microscopic examination, this was seen to consist of oil globules, fatty cells and fibrous tissue. Other cases of ooluria are quoted in which fat particles appeared in the urine. The degeneration commences in the cortex of the kidney, as a rule, and it has been variously ascribed to the agency of bacteria, to alterations in the blood-supply to the organ, and even to its displacement. The latter condition, by producing torsion of the renal vessels, might conceivably tend to cause a necrosis in certain cells, especially in poorly vitalised subjects. Clinically, the disease resembles chyluria, which is more common, and, on the whole, more amenable to treatment. It is doubtful if recovery be ever possible, as the process is a progressive one tending g to the total destruction of the entire renal tissue.

The Cult of the Cradle.
The begeting of children is an accomplishment which deserves to be respected on account of its antiquity. The care of the child is a duty of the first order. One result of town life but rarely referred to is the practical abolition of the cradle, at least in the dwellings of the poor. The cottage cradle has taken a sacred place in folklore and ballad, and country dwellings still manifest the happy appearances of domesticity by retaining this nest for the developing race. In the crowded habitations of our cities, with their rabbit-warren-like tenements and close congregated barracks homes, a crib or a cot takes up far too much space.

It thus follows that in the lodgings of the poor the baby has to find its resting place in the parental bed. This explains in great measure the enormous massacre of infant life from overlying which goes on in our busy centres. Dr. Wynn Westcott, one of the London coroners, has recently shown that maternal inebriety is an etiological factor of great influence in the massacre of infant life, and with the increase of alcoholic indulgence in women it is to be feared that this cause of destruction of young life will increase. According to published statistics during the last ten years 15,000 infants in England and Wales were overlain. In London alone the yearly average of such deaths is 600. And it is to be feared that many cases are overlooked, or hurried up, or appear as "convulsions" in the death certificate. It is manifestly most difficult to substantiate a charge of culpable neglect against these inebriate transgressors, but the loss of life due to the overlying and suffocation of babies by their drunken and neglecting mothers is so great that some way should be found for abating what is now a national disgrace.

The Hygiene of the Third-Class Traveller.
A CYNIC has sought to classify the manners of travellers by declaring that those in the first-class are rude to the guard, those in the second are rude to each other, while to those in the third the guard himself is rude. This is, of course, a gross caricature, for now all sorts and conditions of men and women are wise enough to travel third class. But it must be admitted that from the purely hygienic standpoint the third-class compartment and our third-class companions leave much to be desired. Certain lines the carriages are lacking in many of the essentials for health and comfort, lavatory accommodation is frequently conspicuous by its absence, and cleanliness is unknown. In certain districts, also, travellers in the most unhygienic condition crowd the carriages, and by their filthy condition and filthier habits make the third-class compartment a veritable den of discomfort and disease. It is true one occasionally meets with a shyly-worded request placed in some out of the way corner of a waiting-room or booking-hall requesting passengers not to spit, and even in some carriages there may be an expression of a desire that the seats may not be soiled by filthy boots, but, generally speaking, the officials of our railway companies make but little or no attempt to undertake missionary work in the interests of hygiene, or even seek to promulgate education work for the advantage of their own company. We are all travellers nowadays, and many from the necessities of their work are compelled to spend an important fraction of the day in a railway carriage. It is manifestly of the utmost importance that if the rules of health are to be reduced to their minimum, not only must the stations and carriages be maintained in a high measure of hygienic efficiency, but travellers must be instructed in proper hygienic conduct. During recent years, no doubt, much has been secured, and the public mind is alive to the necessity of enforcing measures
which shall protect against the folly and ignorance of the hygienically neglectful. At this time of the year when every train journeying to the sea or the country seems packed in all its third-class compartments with individuals, many of whom must be considered anything but desirable fellow-travellers, it is most necessary that popular opinion should be awakened to the importance of regulating the commissions and rectifying the omissions of the thoughtless, ignorant and oftentimes altogether selfish non-hygienic third-class traveller.

Hats and Hygiene.

The shape of many a man’s hat is as unchangeable as his habits. The tall silk hat is for not a few the outward and visible sign, not only of professional standing, but of a habit of mind which finds it easier to bear discomfort than deviate from custom. And in almost all ranks of life the same conservative spirit in regard to hats prevails, and it is only the furnace heat of a summer wave that dissevers, and then only as a temporary deviation, the firm forged habits which govern the supremacy of the ordinary male’s head gear. It is needless to point out that our remarks are solely directed to mere men, for woman, ever wise in her day and generation, is accommodating in regard to hat and bonnet, and can be equally charming and respectable with either or neither. Most men suffer much from the hat habit. The inflection of the ordinary and conventional silk hat is accountable for not a few of life’s minor ailments, and unfortunately this form of covering is usually worn under circumstances when the wearer is least able to contend with the shortcomings of his cerebral protector. Far be it from us to suggest any ideal form of head gear, but we would suggest that the principles of hygiene might at least be allowed equal consideration with the claims of habit.

The Formation of a “Health Conscience.”

The summer season of Health, Sanitary and Medical Congresses brings some enlightenment of the national intelligence in matters making for health. It is pathetic to find the eagerness with which many ignorant sufferers search their daily half-penny papers for directing light on hygienic and therapeutic procedures. The press of recent years has done much to awaken and maintain an interest in the physical well-being of the people. A nation’s wealth depends upon a nation’s health, and the recent disgusting reports regarding the physique of a large section of our people may well make serious men and women think earnestly as to the future of our country. Dr. Clouston and Sir Lander Brunton have recently advocated the carrying out of what we may venture to call a home-missionary enterprise: they would develop what has well been succinctly described as “a health conscience.” We cannot boast of a Minister of Health in our Government, and much of our machinery for dealing with matters touching the physical well-being of the country is by universal admission medievale and hopelessly out of date, but a strong public opinion is rapidly growing, and we are of opinion that the formation of a National League for Physical Education, or a Physical Education League, or The National League of Healthy Life would do much, if properly organised, to foster and develop not only sentiment and conscience but an active working intelligence which should be rich in energy for the public service.

Retinal Hemorrhages in Fractured Base.

The diagnosis of fractured base is not always obvious at once, especially if unaccompanied by signs of external hemorrhage. Fractures through the posterior fossa are more likely to give no sign than those involving the anterior or middle. Bearing in mind the close anatomical connection between the sheath of the optic nerve and the arachnoid membrane, it is not surprising to find that in conditions of hemorrhage into the sub-arachnoid space retinal hemorrhages are frequently found. This relationship has been recently studied by Dr. R. A. Fleming, of the Edinburgh Royal Infirmary, who records several instructive cases in the Medical Times and Hospital Gazette. It is stated that retinal hemorrhages are more often seen when the effusion of blood into the subarachnoid space has been rapid, and also that when this is unilateral, the hemorrhages tend to occur chiefly on the affected side. Since the two optic intersheath spaces communicate with each other through the basal sinus, it is not easy to see why the retinal hemorrhages are unilateral, even when the subarachnoid effusion is one-sided. The hydrostatic explanation offered by Dr. Fleming appears to be the most reasonable, according to which the sudden increase of pressure in the subarachnoid space tends to diffuse itself into the intersheath of the same side, at the same time occluding that of the opposite side owing to the production of flattening of the cerebral convolutions on the side distant from the original hemorrhage. These retinal signs, therefore, appear to possess some real diagnostic significance, and should prove of assistance in obscure cases of head injury.

Flies and Summer Diarrhoea.

The summer diarrhoea, which is so prevalent among infants during the third quarter of the year, and which amounts to a veritable scourge in some localities, has received a good deal of attention from time to time at the hands of hygienic experts. The character of the fluid nourishment administered to the children has naturally enough, been subjected to the most minute investigations, and parents have received from medical men careful instructions about boiling or sterilising the milk. In many hospital out-patient departments printed rules regarding infant-feeding are circulated among the mothers bringing their children for treatment. The prevalence of the stone-fruit season has also been held responsible for the production of the malady, regardless of the fact that very young infants are not, as a rule, given such fruit even, by the most
careless or ignorant of mothers or nurses. Likewise, the influence of heat is largely over-rated, for, as a matter of fact, it is when the temperature begins to fall after a period of hot weather that the disease makes its appearance. Even when the food supply is above suspicion, and the infant is apparently in good hygienic surroundings, summer diarrhoea is apt to present itself. In endeavouring to ascertain the reason for this, Dr. E. F. Willoughby, writing in the Sanitary Record, lays stress on the importance of the common house-fly as a probable means of infection, by conveying micro-organisms from neighbouring decomposing animal matter, and then settling upon the food and person of the sufferer. It has been proved experimentally that flies are capable of transporting pathogenic germs by their sucker-like feet, and it is well known that other diseases, such as diphtheria and small-pox, can be conveyed by their agency. In corroboration of this theory is the statement of Dr. Nash, Medical Officer of Health for Southend, that there was not a single death reported from summer diarrhoea during last July and August, in which period there was a remarkable absence of flies, whereas the previous yearly average had been twenty-five for each month. Dr. Willoughby suggests that if a sanitary campaign against flies could be instituted, a diminution in infantile mortality from this cause might be the result.

Fire-Escapes and Tuberculosis.

Owing to the limitations of space in our great cities, the efficient accommodation of those phthisical patients who are desirous of undergoing some form of open-air treatment, and yet who are unwilling to leave their homes, becomes a matter of increasing difficulty. The utilisation of balconies for such a purpose is sometimes practicable, and in suburban villas it is not uncommon to see hopeful and determined patients spending at any rate the daylight hours in these airy resting-places. Some little moral courage is, no doubt, needed, owing to neighbourly prejudices, but these are, happily, gradually being overcome. The outside iron staircases or fire-escapes attached to the tenement houses of New York appear to offer several possibilities in this direction. Dr. Alfred Meyer, of that city, strongly advocates the use of these structures for the outdoor treatment of consumption. Some instances are recorded in which patients have benefited materially by this adaptation of a municipal appliance to the needs of practical medicine. The method has the advantage that the patient is readily accessible to the physician without being obliged to travel many miles to a sanatorium. The objections which might be raised by local authorities to the placing of "encumbrances" upon fire-escapes could, in all probability, be overcome by the practical utility and economy of this new mode of treatment. The patient's bed or couch need not, of course, occupy the entire area of the platform or landing stage so as to block the gangway, while in the event of fire, he or she would be in a most convenient position for rescue.

Flats—Psychology and Physique.

Modern London is rapidly becoming an aggregation of flats. The upspringing of these residential warrens is so important a manifestation of the tendencies of present day city life that no serious thinker can afford to neglect the influence of this far-reaching factor on the life of our people. Flats may be convenient and may present economic advantages, but they are not dwellings which tend to nurture a healthy psychology and perfect the highest type of physique. They may be sociological necessities, but, unfortunately, they do not assist the development of the altruistic citizen, and go far to destroy the best form of domesticity. The aggregation of huge numbers of people in a very limited area has upset all our old bases of calculation. Fresh statistics must be forthcoming if we are to have trustworthy data for estimating the influence of life in flats on the mental and bodily health of those who dwell in these limited-liability-like abodes. The sense of impaired individuality, of lost egoism, which almost inevitably is experienced by the thoughtful flat resident, is not, we conceive, beneficial either to the unit or the State. The lack of responsibility, neighbourliness, and wide sympathy must be harmful to the maintenance of the best type of unselfish citizen. It is well that the drawbacks of flat-life should be clearly recognised, though it would be too much to hope to be able to stem the tide.

Bonded Hospital Medical Officers.

Dr. Bateman, Secretary of the Medical Defence Union, calls attention to a new departure on the part of certain provincial hospitals, the managers whereof require their house surgeons to sign a bond not to practise subsequently within the district. Obviously, if such a proviso became general, it would tend to prevent the best qualified men from soliciting appointments, for although the bond would probably be legally inoperative, a breach of the informal agreement would entail a slur on those who disregarded it. The warning is issued none too early, for such a pernicious innovation, contrary as it is to all ethical principles, should be summarily disposed of. It can only be the outcome of a fear on the part of the medical staff that their junior officers may subsequently select that district for a sphere of practice, and it seeks to enforce a restriction which is utterly unjustifiable.

The Ballaughlish Dispute.

Under the terms of the interdict recently granted against Dr. Lachlan Grant, he will now have to refrain from practising in the district, and the quarry company will proceed to advertise for another medical officer. Meanwhile, the men have appointed a medical man ad interim to take Dr. Grant's place, and it is to be hoped that their praiseworthy persistence will not be stultified by the acceptance of the appointment by any young
medical man on behalf of the company. It is precisely at such junctures as these that the solidarité of the profession may be demonstrated, and any action calculated to weaken it cannot fail to have an unfavourable influence on the status of practitioners in general. We hope, therefore, that the company’s advertisement will remain without response. In any event, the newcomer would have to reckon with a hostile public opinion.

The Care of the Feeble-Minded.

The Association for Promoting the Welfare of the Feeble-Minded is fulfilling a useful mission in focussing attention on the large number of children needing special care and training to compensate for innate mental deficiency. Dr. Shuttleworth has estimated that about 1 per cent. of all children require some form of special education. At the recent annual meeting of the above Society a resolution was adopted expressing the opinion that a Royal Commission should be appointed to investigate and report upon the condition and needs of feeble-minded persons throughout the country. During recent years School Boards and Poor-law authorities have accomplished something for the better protection of these “deficients,” but it must unfortunately be admitted that our present means are all too meagre, and meanwhile large numbers of these “unfit” are joining the ranks of the casuals, prostitutes, inebriates and generally worthless. It would be well if a travelling commission could obtain trustworthy information regarding the present condition of affairs.

The President of the British Pharmaceutical Conference on Medical Dispensing.

In the course of an interesting introductory address delivered by Mr. T. H. W. Idris, J.P., F.C.S., before the British Pharmaceutical Congress at Bristol, the question of medical dispensing is referred to in terms of unqualified condemnation. Disclaiming any trade interest in the matter, Mr. Idris contends that few doctors have had the proper training to become trustworthy dispensers, and that even were it otherwise the practitioner’s duties militate against that concentration of thought which is so essential in the practice of pharmacy—and indeed of any other responsible function. Even more to the point is his contention that by restricting the functions of the prescriber and the dispenser to different hands, one acts as a check on the other and a safeguard is provided against the inevitable, if infinitesimal, proportion of errors. We feel constrained to observe that some of the quotations made use of by the speaker to support his contention are as lacking in conclusiveness as they certainly are in good taste. Unauthenticated stories about “excited” medical men pouring two or three teaspoonsfuls of laudanum into an ounce phial and signing the death certificate in the morning, and the like, savour of libel and detract from the value of arguments which would otherwise commend themselves for favourable consideration. It must be understood that if dispensing ever cease to remain the prerogative of the medical practitioner it will be because the latter has decided against it. We are confident that Parliament would under no circumstances be induced to withdraw that privilege, the more so seeing that the number of mishaps is, after all, miraculously small. Mistakes, fatal mistakes, are far too common in the hands of the qualified pharmacist for it to be safe for him to recklessly fling stones at our glass windows. We should welcome regulations having for object to insure a better pharmaceutical training on the part of practitioners; not only for those who contemplate dispensing their own medicines, but also those who will only prescribe, since a knowledge of pharmacy is as indispensable to the prescriber as to the dispenser. This is a matter which might well engage the attention of the General Medical Council in the near future, since the examining boards do not appear disposed to intervene.

Antistreptococcic Serum.

A correspondent writes:—“Antistreptococcic serum has not received the attention which it deserves from the profession. Failure has followed its use in many cases, the reason for which is not far to seek. In every case before the serum is used a bacteriological investigation of the pus must be made. If streptococci alone be found or if streptococci be in the ascendency, then the use of antistreptococcic serum is followed by most beneficial results. From personal experience I can testify to its usefulness in the following class of cases: Puerperal septicaemia, follicular tonsillitis, diphtheria, in which we have a mixed infection, streptococci being largely represented. This type of diphtheria is usually ushered in with high fever. If antistreptococcic serum be used, followed by anti-diphtheritic serum, the value of the latter under these conditions is greatly enhanced, also in septic pneumonia and in certain cases of infective endocarditis. In one case of very septic throat associated with scarlet fever, in which I found streptococci almost exclusively present, I injected antistreptococcic serum with marked benefit.”

The Pathology of Plants.

Mycot light will doubtless some day be thrown on morbid processes in animals by a more scientific comparison with the derangements of plants. Hitherto vegetable pathology has remained almost entirely a terra incognita. Dr. Ernst Küster, in his recently published “Pathologische Pflanzenanatomie” has broken new ground and in his study of the factors concerned in the etiology and development of diseases of plants has indicated a method which may ultimately prove of much service, both directly and indirectly, to the human subject. We certainly think that the student of medicine in his biological course might well have his attention drawn to the importance of remembering that plants, like animals, may be liable to wide deviation from the normal. It is only by taking the widest possible view as to the
nature of disease that we can hope to unveil the many mysteries which encircle the morbid affections still afflicting mankind.

Poetry and Pathology.

The passing of Mr. William E. Henley recalls to mind the close association of poetry and pathology. Not a few of our most notable poets have felt the buffetings of disease and have borne the scars of affliction, and in every land and in every age the problems of pathology have afforded material which the true singer has dignified in his desires and attempts to unfold and solve. Mr. Henley has endeared himself to many members of the medical profession. His own life was heroic in his combat with suffering and his victory over disease. More than thirty years ago he was a patient of the present Lord Lister, in the old Edinburgh Royal Infirmary, and here his literary career commenced. In Hospital will long be prized as a series of perfect sketches of hospital life and surgical experiences. While a patient in hospital Mr. Henley first made the acquaintance of Robert Louis Stevenson.

PERSONAL.

Dr. G. S. Stephenson, of Grimby, has been placed on the Commission of Peace for the Borough.

Dr. William C. Taylor has been appointed Medical Officer of Health to the West Ham Board of Guardians.

Dr. W. McCallin has been appointed Assistant Medical Officer to the Southampton Corporation.

Dr. William Gabriel Rockwood has been re-appointed unofficial member of the Legislative Council of the island of Ceylon.

Sir W. S. Church will deliver the opening lecture of the winter session at the Post-Graduate College, West London Hospital, early in October.

A Fellowship, founded at Newnham College by Mrs. Sturt, has been awarded to Miss G. L. C. Matthaei, who is investigating the respiration and assimilation of plants.

Mr. W. H. Folker, F.R.C.S., was the recipient last week of a testimonial on velvet congratulating him on the completion of fifty years' connection with the North Staffordshire Infirmary, and expressive of the high appreciation of his services.

Dr. J. L. Stowers has been presented by his colleagues at the North-West London Hospital with a handsome silver salver, the inscription on which explained that it was given "as a token of friendship and in recognition of seventeen years' service as honorary secretary to the Medical Committee."

Professor G. Sims Woodhead, who occupies the Chair of Pathology in the University of Cambridge, has accepted the invitation of the trustees of the Lees and Raper Lectureship to deliver the next lecture on "Recent Researches on the Action of Alcohol in Health and in Sickness," on Monday, November 16th. Dr. Butler, the Master of Trinity, will preside. The lecture will be given in the Guildhall, Cambridge.

[FROM OUR SPECIAL CORRESPONDENT.]

SCOTLAND.

EDINBURGH UNIVERSITY SUMMER GRADUATION.

This ceremony took place on Saturday last, July 25th, in the McEwan Hall, the proceedings opening, as usual, with the presentation of candidates for the honorary degree of Doctor of Law. This degree was conferred on Sir Andrew Fraser, Lieutenant-Governor of Bengal; Professor Laurie, who has recently retired from the Chair of Education in Edinburgh; Sir Henry Normand Maclaurin, Chancellor of the University of Sydney; and the Hon. Mr. Justice Rampini, High Court, Calcutta. Thereafter the ordinary degrees in science, arts, law, and medicine were conferred, and various prizes, scholarships, &c., were awarded. The address to the graduates was delivered by Professor Crum Brown, who took as his subject the well-known yet ever new theme of the progress of the healing art. At the outset he spoke of the changes which had taken place in the University during the past year, and welcomed the new professors of education, theology and Greek among them. As to the progress of medicine during the past forty years, he mentioned the Röntgen rays and other forms of radiation in quite recent times; all these, however, were overshadowed, as they were preceded, by antiseptic surgery, of which it could only be said that by no effort of the imagination was it possible to realise the change it had effected. Progress of an interesting, practical and most important kind had recently been made by the discovery of the mode of action of bacteria and bacterial products on the animal economy. The study of these phenomena had led to a clearer understanding of the cause of immunity. He need not remind them of the pioneer work of Pasteur in the development along modern lines of Jenner's work, which had led to what was now called preventive medicine. There seemed hope now that two of the most fatal of all diseases—tubercle and malaria—might be controlled, as their modes of infection were becoming better known. The address was concluded by an exhortation to cultivate sound and rapid judgment. The practitioner had to make up his mind, and that quickly, as to what ought to be done. Science did not help him here; it was a matter for sound judgment, the same kind of sound judgment that led a business man right in matters of business. Without this no scientific processes of observation, and no manipulative skill, would help their patients. This sound judgment could be cultivated, but could not be made right off; it was not a secret that could be communicated, but most grow. It came from the habitual conscientious performance of duty.

Correspondence.

QUACKERY—MEDICAL AND DENTAL.

To the Editor of The Medical Press and Circular.

SIR,—It seems to me that discussion of this subject well deserves to be continued in your pages. If you agree, perhaps you may feel inclined to accept my contribution towards it. During my career for many years as dental surgeon to a general hospital in London I was brought into relation with large numbers of invalid out-patients. It was not my business to inquire into the question of medical quackery, but the information I casually gained sufficed to show me how terrible is the amount of misery inflicted upon the
poor, the ignorant, and the helpless by the army of
cynical knaves, who as vendors of fraudulent nostrums,
or as quack practitioners, gain their livelihood or amass
wealth by plying upon suffering humanity. If, as
one of your correspondents suggests, a Parliamentary
Committee be appointed to take evidence and report
upon this subject, there can be no doubt overwhelming-
proof will be forthcoming of the necessity
for legislation in the interest of the classes who have
most claim on the guardianship of the State. It
would be shown that, whatever advantage might
accrue to the profession by measures tending to
protect itself, would be far outweighed by the
benefit conferred upon the people. If dentistry as
a branch of surgery were included, as it ought to be, in
the inquiry, a similar result would be attained. The quack
dentist does not directly destroy life, but he inflicts
a vast amount of preventible injury, and carries on a
system of fraud and plunder, and often of blackmail.
The dental quack who practices among the poorer
classes holds out as a bait artificial teeth at prices
which could not possibly provide the materials, even
if necessary surgery could be safely ignored and the
process of fitting the teeth made merely mechanical.
The bait is exactly similar to that used by the quacks of
other departments—ear quacks, obesity curers, and cancer quacks—who mostly offer
a cure for a nominal sum. Some of these rogues, in-
cluding more than one professing to “reduce” fat
people by a miraculous method, spend thousands a
year on advertisements; and it is well known
that a part of their system consists in blackmailing
foolish women who fall into their hands. It
is, at any rate, evident some nefarious means must be
employed to gain an income after spending so large a
sum in advertisements. In a similar way the cheap
dental quack never gives a patient a set of teeth for
the price advertised, and more commonly extorts ten
or twenty times the amount for worthless work. Two
cases have lately come to my knowledge in each of
which £20 was taken from lower class patients by an
infamous firm who advertise sets of teeth for a few
shillings “warranted.” The teeth supplied were useless.
The dental quack who lays himself out for wealthy
patients works, as a rule, under cover of a sham Ameri-
can institution. There are many of these in London
and throughout the Kingdom. Their proprietors,
some of whom own several establishments, often work
with the aid of the Limited Liability Act, and often
make large incomes. They carry on their trade by
means of gangs of unqualified assistants, often Ameri-
cans, or able to palm themselves off as such. These
men are paid salaries and a share of the plunder from
each patient. No self-respecting qualified man, who
was not a complete failure in his profession, could
possibly serve in such an establishment. Every
patient who goes there is, of course, treated with the
main consideration of getting as much money out of
him as possible. Every dental surgeon in London of
wide experience could fill many of your pages with
narratives of cases within his own knowledge in which
wealthy patients—mainly women—have been de-
ceived of large sums and cruelly used by improper
treatment in the hands of the sham American dentists.
It is these patients who so often return, after a time,
to their family dentist with a narrative of their ex-
periences. Sometimes, although rarely, a male rela-
tive intervening compels a quack to disgorge his ill-
gotten fees. But as a rule the quack finds impunity
in the fact that there is nothing a woman will not
dure under the circumstances rather than expose her
honor publicly in a court of law.

I remain, Sir, your truly,
HOSPITAL DENTIST.

Mr. Victor G. Pfarr, the well-known Librarian
of the Royal College of Surgeons of England, has written a
Adlard and Son, which medical men, ambitious to be authors, would do well to study seriously.
THE PRINCE OF WALES AND THE HONORARY MEMBERSHIP OF THE B.M.A.

The "first gentleman" in the land has always evinced the deepest interest in matters medical, and has not been slow to recognise the honourable place which medical men occupy among the best workers for the weal of the nation. It is, therefore, particularly pleasing to find the Prince of Wales following the example of his father, the King, in extending the sympathy and support to "the doctors of Wales." The first duty of Dr. Griffiths, the new President of the British Medical Association, is a particularly pleasing one, being to move the following resolution:—

"That the Prince of Wales be and is hereby elected an honorary member of the British Medical Association, not only for the honour his membership will confer on the Association, but for the distinguished services his Royal Highness has rendered to the medical profession."

Literature.

BROUARDDEL ON DEATH AND SUDDEN DEATH (a)

This second edition appears five years after the first, and the slightly increased bulk of the volume is fully justified. The translator has extended the range of the subject matter and added further illustration, detail, and comment, which adds completeness to the work, and also the volume remains a concise and convenient source of information on many practical points on which at some time or other every medical man finds himself in doubt or difficulty. The new matter, which is mainly drawn from British writers, is indicated by brackets, and the sources from whence obtained are in all cases acknowledged. Dr. Brouarddel, so long Director of the Morgue, has had vast experience of medico-legal cases; in fact, the author's name furnishes sufficient guarantee that the information offered will be valuable, and the translation of the text by Dr. Benham leaves nothing to be desired.

The first part of the volume is devoted to the signs of death. This somewhat dry subject is here presented in an attractive form, and affords most interesting reading and valuable information. The possibility of determining the exact instant of death—apparent death (premature interment)—the real signs of death and the question of asphyxia, with the proof of death are fully discussed. The second part of the volume deals with sudden death, which, apart from the effects of violence, is the "rapid and sudden termination of an acute and chronic disease which has in most cases developed in a latent manner." Commencing with sudden death due to lesions of the circulatory system, sudden death due to lesions of the other systems are fully described, and numerous examples given. The most frequent form of sudden death, according to Dr. Brouarddel, is death due to the kidneys, the renal lesion not always being the only factor, but a combination of causes, which make the mechanism of this kind of sudden death difficult to determine. Death supervenes from auto-intoxication in such cases. When death is suspected to be due to embolism he points out the importance of not performing a post-mortem examination by the usual method, for in order to remove the thoracic organs the relations of the parts are changed, the clot is displaced, and will not be found in situ. Therefore, to obviate this, he recommends opening the chest freely and the pericardium, and the dissecting of the heart in situ. On removing clots formed during the last hours of life, and following the ramification of the pulmonary artery, if there be an embolism it is found without difficulty, and the broken surface of the lung thrown into the pleural cavity can be compared with the remainder of it left in the vein where the thrombus was formed. Many and similar useful practical hints are given which make this work invaluable to the medical man who is called upon to report upon a sudden death or to conduct a post-mortem examination in such cases.

Each chapter leaves nothing to be desired in the way of precision and clearness. Innumerable cases are quoted to illustrate the text, some of which are sufficient to arouse incredulity. The sources from which they have been derived are, however, in all cases acknowledged. It is a book to which the medical man may turn in moments of anxiety or doubt, and in which he is sure to find help and guidance. It will also create a sense of comfort, knowing he has such a work to refer to, so much is dealt with which cannot be found in works of medicine or medical jurisprudence.

A SHORT MANUAL OF INORGANIC CHEMISTRY. (a)

This work, which has been revised and brought thoroughly up to date, meets the need which many teachers will have felt in providing for students a handbook at an exceedingly moderate price, which contains practically all that the advanced student requires for an intelligent grasp of the principles by which his work is governed. Special attention has been paid to the fundamentals of the periodic law, and, speaking generally, it will be found on studying the work that the authors, while dealing with the subject from a thoroughly practical point of view, have not been inclined to the modern method of treating similar forms of "pollution" in water. This sentence is, of course, qualified by its context, but we would point out that, while not seeking to diminish the value of bacteriological examination of potable waters, there are hardly any recorded cases in which a proper chemical examination has failed to show contamination which has subsequently been revealed by a biological investigation. It is to be regretted that the authors did not devote a little more space to the question which to the extensive use of waters for drinking and for other purposes, seeing that every student ought to possess a fair general knowledge of this important subject.

The electrolytic processes for alkali production are mentioned, and will doubtless be further detailed in subsequent editions. We note with satisfaction that the authors give an indication of the physiological action of the various salts dealt with. This is, in our opinion, a feature highly to be commended.

The subject of crystallography is well dealt with and illustrated with well-drawn diagrams. The book is well got up, with clear print, and so far as we have been able to examine it, is remarkably free from misprints.

POORE'S SANITATION, (b)

This small volume consists mainly of extracts taken from the author's "Milroy Lectures," and his book, entitled "The Dwelling-House." He deals with the question of the relation of flies and feces to the propagation of disease. He advocates the burial of fecal matter in shallow furrows, which are then filled in on the earth, and the soil may be used for the growing of vegetables. The rest of the book is taken up with a detailed description of a model cottage,

with an ingenious special tank for the collection of rainwater, and in a scheme for the disposal of slops by means of a filtration gitter. In addition, the author gives practical hints on earth closets, dry urinals, the housing of animals, and the construction of wells. Its pages will certainly find favour with those who desire information; no doubt the author's style is the broad and accurate in the expression of his opinions.

WARWICK AND TUNSTALL'S FIRST AID. (a)

At the present time, more so perhaps than ever before, there is a growing tendency to popularise medicine and surgery. Ambulance instruction, though of the greatest possible service, is apt to lead those attending such lectures to suppose that they are thereby qualified, not only to give first aid, but also to practically all ailments and accidents that may come in their way. Nothing could be more fatal to progress. We make these remarks because in the ably-written manual before us, fear of first-aid tendency to impart too much information, especially in the earlier chapters devoted to anatomy and physiology. In fact, the book is so replete with information that even the over-concerned for its clinical reference in cases of emergency. The chief alterations in this edition are an increase in the number of illustrations and an improvement in some of the original diagrams. Ambulance learners will derive much help from its careful perusal.

NEW BOOKS AND NEW EDITIONS.

The following have been received since the publication of our last list—

Diseases of the Stomach. A Text-book for Practitioners and Students. By Max Einhorn, M.D., Professor of Clinical Medicine in the 5th Graduate Medical School and Hospital. Pp. 600, with 74 illustrations. Price 4s. 6d.

Proctor and Disease. By J. Jackson Clarke, M.B., L.R.C.P., F.R.C.S. Pp. 188, with 31 original illustrations. Price 7s. 6d. net.

Uterine and Tubal Gestation. A Study by Samuel W. Hadler, M.D. Pp. 158, with 83 illustrations. 7s. 6d. net.

John Bell & Sons. (London).

Cassells & Co. Ltd. (London).

An Inquiry Into the Etiology and Pathology of Beri-Beri. By Hamilton Wright, M.D. Pp. 93. Price 3s. 6d. net.

FELIXIR.

This is a very pure spirit with a flavour recalling that of juniper berries. It has been doubly rectified, and hence is remarkably free from fuel oil. We have personally visited the factories, Booth's Distillery, Cow Cross Street, London, where it is prepared, and are therefore, in a position to speak as to the remarkable care and cleanliness displayed there.

The flavour and taste are of themselves sufficient proof that it has been thoroughly rectified and has matured for a considerable time. The extracts are usually under half one per cent., and the sugar present is very small, not exceeding 0.2 parts per cent. We consider this to be a thoroughly wholesome and well-matured spirit, fitted for medicinal application, on account of its great purity, especially in those cases in which malt whisky is productive of biliousness. Its alcoholic strength is quite satisfactory, being over ten degrees, about the statutory limit.
TRISCUIT.

The manufacturers of "shredded wheat" now prepare a product to which they have given the name "Triscuit." This is a thrice-cooked biscuit possessing considerable merit and novelty. The finely divided thin pieces of crisp wheat grain allow of more perfect cooking than would be possible in any form of bread, and would also facilitate more perfect admixture with the salvia and gastric juices.

Analytically its composition is manifestly superior to the best bread, and the sample submitted has yielded the following results:—

- Moisture, 6 per cent.
- Mineral matter, 1 per cent.
- Nitrogenous matter, 3.2 per cent.
- Ash, 1.2 per cent.

These figures show that the substance is practically all nourishment, the difference between them and 100 being, of course, carbohydrates. It is to be noted that while Triscuit contains only 6 per cent. of water, the best bread generally has 30 per cent. thereof.

This article should prove of very great value as a substitute for toast, but it can easily be converted into an appetising sweetmeat. We have exposed part of the sample submitted to conditions of temperature and moisture such as would be met with in the tropics for a considerable period, and it remained perfectly uninjured and palatable.

COW'S HEAD BRAND CONDENSED MILKS.

We have received for examination from the Swiss Milk Society (Peninsular House, Monument Street, E.C.) two samples of Cow's Head brand of condensed milk—one slightly sweetened, the other unsweetened. The qualities of a rich, genuine milk, and are highly creditable preparations.

The unsweetened brand yielded the following figures on analysis:

- Fat ........... 12.0
- Albuminoids ...... 9.4
- Milk and sugar .... 13.3
- Ash ........... 1.8

These figures are well above the average for good condensed milk, suggested by Mr. C. G. Moor in his masterly work on "Standards for Purity for Foods and Drugs."

The sweetened sample gave nearly the same figures for fat, milk-sugar and nitrogenous matter, but we were pleased to find that the added sugar, which in most brands is objectionably high, was low, so that when diluted the milk is free from excessive sweetness. We consider these milks as types of what condensed milk should be, and have pleasure in commending them to the notice of our readers.

SOLUBLE SALTS OF MANGANESE AND IRON.

We have received from Messrs. Burroughs Wellcome and Co. samples of soluble salts of manganese, and manganese in combination with iron, six, manganese citrate, manganese and iron citrate, and manganese and iron phosphate. All three are in the form of scales, and are readily soluble. Although it is well known that manganese is therapeutically useful in the treatment of anemia and allied conditions, it has not come into general use by reason of the lack of soluble salts thereof. This lapsus has now been remedied, thanks to researches carried on in the Welcome Research Laboratories, and we have the choice of three very elegant and useful products. These salts can be had either in scale form or as tablets.

The writer of an interesting sketch on the fashionable resort of Plombieres, in the current number of Travel, declares that "it is a well-known fact that out of every six persons one knows at least four have either already had, are at this moment having, or intend soon having appendicitis," and it is suggested, "it is always safe with strangers to say courteously, 'I presume you have had appendicitis?'—it leads to an animated comparison of symptoms and does away with the idea of awkwardness of opening.

From all this it would seem that Plombieres is hardly likely to prove a paradise for the few remaining non-appendicular subjects.

Westminster Hospital Medical School.

The annual distribution of prizes took place on the 18th inst., in the presence of a large gathering of the students and their friends, the members of the staff, and governors of the hospital. Lord Strathcona was to have presided, but owing to an injury to his foot he was unable to be present. In his unavoidable absence, the prizes were presented by Mr. G. V. Yool, Chairman of the School of Medicine Committee. The prize list was as follows:—J. A. B. Hicks, scholarship of 110 guineas; J. N. Beadles, scholarship of 90; G. G. James, scholarship of 40; A. W. Browne, scholarship of 40; H. G. Curtis, scholarship of 40; W. C. Nimmo, Chadwick prize of 20 guineas for medicine and surgery; C. Parker, "Bird" medal and prize of the value of £14 for obstetric medicine; G. G. James, Treasurers' prize of 10 guineas for anatomy, biology, and chemistry; J. J. W. Evans, prizes for practical chemistry and physics; H. Galloway, prize for biology; J. Cromie, prize for midwifery; C. Fletcher, prize for histology; W. France, the prize for pharmacology and the prize for medicine; W. Ball, prize for pathology; C. G. Browne, prize for anatomy; R. Elworthy, prize for physiology. In moving a vote of thanks to the chairman, Mr. W. G. Spence, F.R.C.S., expressed regret at the absence of Lord Strathcona, who had taken so deep an interest in the medical side of university education. He also alluded to the affiliation of the several medical schools to the University of London, and hoped that the University would make some provision soon for relieving the medical schools from the teaching of elementary science.

Death Under Chloroform.

An inquest was held on the 17th inst. on a child, fifteen months of age, who had died at the Royal Berks Hospital while undergoing an operation for empyema. The usual verdict was returned.

The Carmichael Prize Essay.

The President and Council of the Royal College of Surgeons in Ireland will, on the first Thursday in November, 1904, proceed to adjudge a prize of £20 to the best essay that may be presented to them, in accordance with the following instructions prescribed by the late Mr. Carmichael:—"(1) "The state of the medical profession in its different departments of physiology, surgery, and pharmacy, in Great Britain and Ireland, at the time of the writing of the prize essays." (2) "The state and mode of examination, or of testing the qualifications of the candidates, for the licensing colleges or corporations of medicine, surgery, and pharmacy." (3) "The state and mode of examination, or of testing the qualifications of the candidates, for the licensing colleges or corporations of medicine, surgery, and pharmacy." "Under these heads the authors will be pleased to make such suggestions as may occur to them respecting the improvement of the profession, with the view of rendering it more useful to the public, and a more respectable body than it is at present. In these suggestions the authors will be pleased to consider the preliminary and moral education of medical and surgical students, as well as the mode of conducting their professional studies." "In considering the third head, or mode of testing the qualifications of candidates by the licensing bodies, the authors will please to consider the most practical mode of rendering the examination as demonstrative as possible,—i.e., in anatomy, by having the dead subject placed before the candidate; in chemistry, botany, and pharmacy, by examining the specimens of minerals, plants, and pharmaceutical preparations placed before him; and in the practical subjects of physic and surgery, the candidate to be placed before the patients in the wards of an hospital, as the testator is certain that this will afford the most certain and only true mode of testing the qualifications of candidates."

The essays must be lodged at the College on or before July 1st, 1904. Further particulars will be found in our advertising columns.
The Cambridge Small-Pox Epidemic.

The Cambridge Small-Pox epidemic continues to spread at Cambridge, and up to Saturday last there had been ninety-two cases with five deaths. Vigorous measures have been taken to prevent the further spread of the disease, and vaccination is being proceeded with on a large scale.

The Jenner Institute of Preventive Medicine.

At a special general meeting of the members of this institute on the 22nd inst., a resolution was unanimously passed to change the name to "the Lister Institute of Preventive Medicine." A change which, apart from the technical need for an examination of the aims and object for which the institution was created, a second meeting will be held on the seventh prox. to confirm the resolution.

Medical Address to the King in Ireland.

On the occasion of their Majesties' visit to Dublin last week the Presidents and Fellows of the Royal Colleges of Physicians and Surgeons presented loyal addresses, offering a most enthusiastic welcome on this the first occasion on which his Majesty since his accession to the throne had been graciously pleased to honour the city and Dublin generally with his august presence. As representing the profession of medicine, the addresses regarded with grateful appreciation the intelligent favour which his Majesty had ever extended to it and the great interest he had taken in its efforts for the advancement of medical science, as well as for the preservation and improvement of the health of the nation. Reference was especially made to his having saved the object the checking of the fatal ravages of cancer and tuberculosis. The Colleges also begged to offer a loving welcome to her gracious Majesty Queen Alexandra, who, on the occasion of her previous visits as Princess of Wales, had won a secure position in the affections of the Irish people. The Royal Academy of Medicine, Dublin University, the Royal University of Ireland, the Apothecaries' Hall, the Pharmaceutical Society of Ireland, Royal City of Dublin Hospital, Royal Hospital for Incurables, Mercer's Hospital, Adelaide Hospital, Incorporated Dental Hospital, and the Matrons and Nurses of Dublin also presented loyal addresses to the Majesties, all of which were graciously accepted and thanks duly returned.

Central Midwives Board.

A meeting of the Central Midwives Board, Dr. Chambers in the chair, was held at the Privy Council Office, Whitehall, S.W., on Thursday, July 23rd, when the following business was transacted:—1) The Secretary reported that, subject to the confirmation of the Board, it had made an arrangement with Mr. Spottiswoode and Company for the sale of the Board's publications, including the rules, forms, and midwives roll. The action of the Secretary was approved. 2) The Secretary was instructed to advertise for a lady clerk at 3s. per week, to enter on her duties when the Board takes possession of its new office at 6 Suffolk Street, about the middle of August. 3) A letter was read from the Clerk of the Council enclosing a copy of the rules as revised by the Privy Council after consideration of the representations made by the General Medical Council, the Home Office, and the Local Government Board. After discussion of the suggested amendments, some of which were accepted and others modified, the Secretary was directed to return the rules to the Privy Council, with the observations of the Board on the alterations made. It is not anticipated that any difficulty will now arise to prevent the approval of the rules by the Privy Council at an early date.

Mr. Alexander Joseph McAuley Blayney, F.R.C.S.I., has been appointed Surgeon to the Mater Misericordia Hospital, Dublin. Mr. Blayney has for some years past been one of the assistant surgeons of the institution.

Conjoint Examinations in Ireland.

The following candidates have passed the Second Professional Examination, Part II., by the Royal Colleges of Physicians and Surgeons:—

Third Professional:—

1. Honours (in order of merit):—Miss A. M. Barry and Miss L. E. O'Meara, equal; G. A. D. Harvey, M. Keane, Miss G. W. Clarke.

Anniversary Address.

At the graduation ceremony on Friday last, July 24th, the degree of Doctor of Medicine (M.D.) was conferred on the following:—

Cruckshank, Wm., M.B., Petrie, J. M., M.B., Ch.B. C.M.

Reid, Alec. W., M.B., M.C. M.C.

Dunwoody, A. M., M.B., C.M. (Highest Honours for Stephen, G. M.B., C.M.

Tindall, F. M., M.B., C.M.

Fraser, S. J., M.B., C.M., C.M. (Trotter, R. S., M.B., C.M.

Geddes, G., M.B., C.M.

Tuach, W., M.B., Ch.B.

Gibb, G. A., M.B., C.M.

Cochrane, A., M.A., M.B., B.M., Ch.B.

Jamieson, A. M., M.B., C.M.

Murray, C., M.A., M.B., Wishart, J., M.B., Ch.B., Ch.B. (Highest Honours B.Sc."

In the latter Degree of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) (New Ordinances) were conferred on the following:—

With Second Class Honours:—Alexander Newton Callum, Wm. Clark Southern.

Diploma in Public Health:—George Grant Macdonald, M.A., M.B., Ch.B.

" Commendation " for Thesis.

Mr. Howard Marsh, F.R.C.S., Surgeon at St. Bartholomew's Hospital, London, has been elected to the Professorship of Surgery in Cambridge University.
NOTICES TO CORRESPONDENTS.

JULY 20, 1903.

Advertisements.

BUTLER, WILLIAM, M.B., C.M. Univ., D.P.H., London, Medical Officer of Health of Withams.

GILL, J. W., D.P.H., London, Surgeon and Agent for the care of Sick and Wounded Seamen and Mariners at Llanwyrta Major by the Admiralty and Medical Officer to the Yacht Llwyn Isaf by the Yacht Llwyn Isaf, 1st Class, Trinity House.

MILLER, J., M.R.C.S., L.R.C.P. Lond., Medical Officer to the Troops stationed at Exeter.

O'BRIEN, A., M.R.C.S., L.R.C.P. Lond., Medical Officer of the Ulster County by the Barracke Board of Guardians.

PARKER, H. C., M.B., L.R.C.P., London, Medical Officer to the Royal Naval Hospital.

RICHARDSON, R., M.D., L.M.S., L.R.A.C.P., London, Medical Officer of the north of England by the National Insurance Board.

WAR, J. P. S., M.R.C.S., L.R.C.P. Lond., Medical Officer of Health for the Borough of Hove.

Vacancies.

Stockport Infirmary.—Assistant House and Visiting Surgeon, Salary £60 per annum, with board, washing, and residence. Applications to the Secretary.

Birkenhead Borough Hospital.—Junior Male House Surgeon. Salary £50 per annum, with board and washing. Applications to Hon. J. H. Bayes, Town Clerk, Town Hall, Birkenhead.

Liverpool Dispensary.—Assistant Surgeon. Salary £10 per annum, with board and washing. Applications to Dr. A. T. S. Armstrong, 104, Mount Street, Liverpool.

Royal Lancashire Infirmary.—House Surgeon. Salary £20 per annum, with board and washing. Applications to the Secretary.

George.—On July 31st, at Beverley, East Yorks, the wife of W. Herbert Gregory, M.D.Edin., of Beverley, Editor of "The Lancet," and of Surbiton, M.C., a son.

GRIMMELL.—On July 21st, at 5, Windosr Place, Cardiff, the wife of Cornelius A. Grimmell, F.R.C.S.I., of a son.

GRIMMEL.—On July 18th, at Cambridge Terrace, Dover, the wife of Charles E. Murphy, L.R.C.P., L.R.C.S.I., Irel., prematurely, of a son (stillborn).

RUTHER.—On July 22nd, at 28, Beaumont Street, Oxford, the wife of James Ritchie, M.D., of a daughter.

THOMPSON.—On July 25th, at 15, Northbrooke Street, Newbury, the wife of Arthur Thompson, B.A. (Cantab.), M.R.C.S., L.R.C.P., of a son.

Marriages.

BAYLOR.—On July 22nd, at St. John's Church, Lancaster Gate, Presentation of the Left of the late J. B. Bower, to Amy Cecilia, only daughter of the late Mr. and Mrs. G. C. of 13, M.I.C., of Surrey Road, Bournemouth.

BARKER.—On July 25th, at Holy Trinity Church, Mission, Congleton, Cheshire, Robert Roxburgh, M.R.C.S.E. (Edin.), of Westerton, Super-Mare, son of the late Rev. John Roxburgh, D.D. of Glasgow, to Ellen Fanny, the daughter of the late Thomas Rouse Esq., of Tunstall, and Brampton Lodge, Newcastle, Staffordshire.

Health.

MURRAY.—On July 24th, at 56, Addison Mansions, W. J. Ivor Murray, M.D., F.R.C.S.E., late Colonel Surgeon, of Hong-Kong.

OPERATIONS—METROPOLITAN HOSPITALS.

WEDNESDAY.—St. Bartholomew's (1.30 p.m.), University College (1 p.m.), Royal Free (2 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. Thomas's (2 p.m.), London (3 p.m.), King's College (4 p.m.), St. George's (Ophthalmological), St. Mary's (2.30 p.m.), National Orthopaedic (10 a.m.), St. Peter's (2 p.m.), Samaritan (3.30 a.m. and 2.30 p.m.), St. Ormiston Street (9.30 a.m.), St. Northern Central (9.30 a.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Cancer Research (2.30 p.m.), Throat, Golden Square (2.30 p.m.), Great Northern Central (2.30 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), St. Mark's (2 p.m.), Samaritan of 9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), Guy's 1.30 p.m.),

FRIDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Charing Cross (8 p.m.), St. George's (1 p.m.), King College (2 p.m.), St. Mary's (5 p.m.), Opitithalma (10 a.m.), Cancer (2 p.m.), Chelsea (2 p.m.), Great Northern Central (2.30 p.m.), West London (2.30 p.m.), London Throat (9.30 a.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), City Orthopaedic (2.30 p.m.), Scoo Square (2.30 p.m.), Great Northern Central (2.30 p.m.), Great Northern Central (2.30 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), St. Mark's (2 p.m.), Samaritan of 9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), Guy's 1.30 p.m.),

SATURDAY.—Royal Free (9 a.m.), London (2 p.m.), Middlesex (1.30 p.m.), St. Thomas's (2 p.m.), Westminster (2 p.m.), Chelsea (2 p.m.), Samaritan (Gynaecological, by Physicians, 2 p.m.), Scoo Square (2 p.m.), Royal Orthopaedical (2 p.m.), Great Northern Central (2.30 p.m.), West London (2.30 p.m.), London Throat (9.30 a.m.), Royal Free (2 p.m.), Guy's 1.30 p.m.)

MONDAY.—London (1 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), St. George's (2 p.m.), St. Mary's (5 p.m.), Middlesex (2 p.m.), Chelsea (3 p.m.), Great Northern Central (2.30 p.m.), West London (2.30 p.m.), London Throat (9.30 a.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), City Orthopaedic (2.30 p.m.), Scoo Square (2.30 p.m.), Great Northern Central (2.30 p.m.), Great Northern Central (2.30 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), St. Mark's (2 p.m.), Samaritan of 9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), Guy's 1.30 p.m.),

TUESDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Westminster (2 p.m.), West London (2.30 p.m.), University College (2 p.m.), St. George's (1 p.m.), St. Mary's (1 p.m), St. Mark's (2 p.m),) of the University of Athens. Salary £50 per annum. Applications to J. Austin Jenkins, University College, Cardiff.

Somerset and Bath Asylum, Cotford, Taunton.—Assistant Medical Officer, Salary £160 per annum, with furnished apartments, board, fuel, lighting, and washing. Applications to the Secretary, University of Athens.
OBSERVATIONS ON THE EVOLUTION OF ABDOMINAL SURGERY,
FROM PERSONAL REMINISCENCES EXTENDING OVER A THIRD OF A CENTURY AND THE PERFORMANCE OF 2,000 OPERATIONS (a).

By A. W. MAYO ROBSON, F.R.C.S., Hunterian Professor of Surgery and Pathology, Royal College of Surgeons of England.

It is clearly impossible in a short time to even briefly record all the advances made in surgery, but in my work as a general surgeon I have also had the privilege of taking part in the development and progress of a special branch, abdominal surgery, than which nothing could better exemplify the great changes that have occurred during the thirty-three years which I am considering; for, in the early seventies, abdominal diseases were practically always treated expectantly, and if we look at the reports for 1870 we shall see that, judged by results, it was perhaps just as well that surgery had then no business inside the abdomen. As knowledge increased, and surgery became more scientific, many of the diseases in question became surgical either from the beginning or at a later period in their course, so that to-day abdominal surgery is a subject of the first importance. Formerly, ovarian disease was generally known as a form of dropsey, and was either treated by tapping, when the pressure became so severe as to demand some relief, or seeing that tapping was at times fatal or only gave a temporary relief, the greater number of cases went untreated. The surgery of the intestines, except for strangulated hernia, was not thought of, and uterine, renal, gall-bladder, stomach, liver, and pancreatic surgery were hardly dreamt of as possible. In 1870 an attempt was being made in some of the general hospitals to emulate the example set by certain pioneers, such as Clay, of Manchester, Spencer Wells, of London, and Keith, of Edinburgh.

The rise and progress of abdominal surgery has centred more around ovariotomy than any other branch of work, hence it may be of interest to review for a moment the evolution of that operation, for it has been the battlefield of abdominal work. I remember in the early seventies, when there was no special preparation of ligatures, which were of silk used straight out of the storage cabinet, and often handed to the surgeon by the theatre porter, who might even be post-mortem attendant; when little care was spent on cleansing the surgeon’s hands and none on cleaning the patient’s skin; when a perfunctory washing was supposed to be sufficient for instruments, and a very superficial cleansing to be ample for sponges, which were doubtless the most fertile source of mischief. The surgeon then wore a non-washable operating coat to protect his own clothes from being soiled, and not, as now, a sterilized overall to guard his patient from contamination.

The introduction of antiseptics started the change, but at first and for some years, carbolic acid was by many thought to act like a fetish, and to cover a multitude of sins. Then came a reaction against the use of antiseptics, and a veritable crusade, with much acrimonious writing, was led off by Lawson Tait, who argued that antiseptics were not only unnecessary to success, but were actually injurious. But his success came from another discovery, for, although he was by no means what we should now call an aseptic surgeon, as shown by his results in other than abdominal wounds, his genius found a different way, for he taught us the value of natural drainage through the intestines, and the importance of the avoidance of morphine. He made a routine practice of purging after operation, and so avoided that distension which used to kill so rapidly in early ovarian work. Had purging and the avoidance of morphine been adopted in the early seventies I have no doubt that the large mortality of that day would have been materially lessened. Other lessons I learnt from Lawson Tait were the value of rapidity in operating and of thoroughness in the removal of disease, for in early work on the uterine appendages it was not at all uncommon for the surgeon to be deterred by adhesions, and to rest satisfied with the drainage of pus tubes and cysts, instead of their complete removal, with the result that such patients either remained invalids or died more rapidly than if they had never been treated. Under perfected technique, and a judicious combination of asepsis and antisepsis, ovariotomy has become one of the most successful major operations in surgery, and has paved the way for other equally great triumphs within the abdomen.

The discovery of the frequency of perforative appendicitis, of perforating gastric ulcer, and of other peritoneal catastrophes is gradually abolishing the term acute peritonitis for the more rational one of acute peritoneal infection, for the treatment of which surgery alone is of any use, and even for it to be of service operation must not be long delayed.

Up to 1883 every case of intraperitoneal rupture of the bladder had died, but in that year the late Sir William MacCormac operated on and saved two lives; since that time there have been 54 operations recorded (according to Dr. Jones) (a), out of which 28 recovered. Could these cases have been seen earlier, the saving of life would have been much greater, for in the cases that recovered there had only been an average interval of 31 hours between the accident and the operation, whereas in the cases that died the average interval had been 32 hours, and of the 26 deaths, 17 were due to peritoneal infection. Just as in gastric ulcer, the danger is increased with every hour of delay between the accident and operation; hence in case of doubt, exploration (which can be done through a very small incision, just sufficient to admit the finger) is safer than waiting, and experience shows that the aiding of the diagnosis by the injection of air or fluid into the

(a) Abstract of an Address in Surgery at the annual meeting of the British Medical Association at Swansea, July, 1903.

(b) "Annals of Surgery," June, 1903.
bladder adds to the risk of general peritonitis by spreading infection over the whole abdomen.

In injuries of the abdomen by penetrating wound, when the vital organs of the pelvic cavity have been exposed to danger of septic contamination, the surgeon must be prepared to bear the shock of a sudden and unexpected disaster, and to make the most of the means at his disposal, without wait and loss of time, so that the patient may be transferred to a hospital where a trained and competent surgeon is ready to meet the emergency.

Appendicitis of the acute, perforating, or gangrenous type comes on so suddenly as often to constitute a peritoneal catastrophe, and in a proportion of cases terminates fatally in so rapid a manner that the diagnosis is made only with great difficulty, or not at all. The disease is said to be on the increase, but I am not at all clear as to the truth of this, as there have been many cases reported in which the disease has been cured by prompt and efficient treatment. In many cases, I believe, the disease has been cured by the use of the proper remedies and by the proper treatment of the case, and it is almost certain that the disease is more common than it is generally supposed.

The evolution of the operation of hysterectomy has been one of the most interesting and important operations of the age. The first operation was performed by Koebele's urethrotomy, and the operation was performed by Koebele's urethrotomy.

Panhysterectomy, or removal of the whole uterus by the abdominal route, has been advocated by Doyen, and when I saw him operate years ago I could not help thinking that the operation was a most simple and safe one. The operation was performed by Koebele's urethrotomy, and the operation was performed by Koebele's urethrotomy.

Freud advised the abdominal operation for removal of a cancerous uterus, but a mortality of nearly 70 per cent. in 106 published cases caused its abandonment for a time, though after the introduction of the Trendelenburg position it became comparatively easy of performance, and, as it is thorough, it should certainly be the operation of choice whenever there is the slightest suspicion of malignancy, or when the myomatous growth extends down into the cervix.

As showing the feasibility of this method, I have recently operated successfully on a patient at the advanced age of 72, who had no more shock than after some simple operation. Where the cervix is chiefly involved and the broad ligaments and lymphatic glands are free, the vaginal operation will, however, still be the operation of choice.

The surgeon has all the methods, and have come to the conclusion that it is better to be circumspect and to treat each case on its merits.

The surgery of the bile passages is one of the most interesting episodes in abdominal work, for, although the first cholecystotomy was performed so far back as 1867 by Bobbs, of Indianapolis, it is only within recent years that surgery has come to be recognized as the treatment for gall stones. I performed my first cholecystotomy in 1881, and operated nearly 600 times on the gall bladder and bile ducts. At first cholecystotomy only was practised, with the result that the ducts were often left obstructed and fistula necessarily followed. Common-duct operations, performed by using a guarded and carefully performed incision and without the use of the liver, which I introduced some time ago, are now as easy as an ordinary cholecystotomy used to be, for an improved method enables the whole of the biliary ducts to be brought near to the surface, and to be deliberately dealt with.

Nothing could demonstrate this better than the results in my own practice in an experience of over 100 cholecystotomies, for, whereas in my first series before 1900 the rate of mortality was 23.8 per cent., in my last series it is only 1.5 per cent., and I have had a considerable series of 50 cases without a single death. Therefore, it must be borne in mind that nearly one of every ten of these cases is not merely a successful operation, but a life saved, for common-duct cholecystitis associated with infective or suppurrative cholangitis and deep jaundice is mortal malady.

Fortunately, gall stones are usually easily diagnosed, the symptoms are classic, and in the early stages, before complications have supervened, cholecystitis is curable by surgical methods in 99 per cent. of cases, as I myself have demonstrated in a large series of operations: but if we wait for complications to supervene, and for the onset of jaundice and various infections, or until cancer has invaded the liver and gall bladder, which it does ultimately in 50 per cent. of cases in which jaundice is present, then there will be a very different tale to tell.

Even yet we do not get these cases always in time, and as the fact is generally accepted that medicine can, as a rule, only relieve and cannot cure cholecystitis we shall be continually having to operate in the presence of serious complications, endangering life, when operation is five to ten times as dangerous than if it had been undertaken at an earlier stage.

The surgery of the liver was, until recent years, limited to the evacuation of abscesses and hydatids, and it is interesting to note the evolution of the various methods following closely one on the other: of emptying by trocar or aspirator; of opening by caustic or thermo-cautery; of incision à deux temps; and, lastly, of the method which we now generally adopt — the abdominal approach — the liver being reached after the thoracic approach has been made. The liver is then reached through the abdominal parietes or, if necessary, through the thoracic wall — an operation the credit of which must be given to Lawson Tait, who published a first series of 10 cases between 1873 and 1882, all successful. At first sight it would seem impracticable to remove a tumour of the liver, but experience shows that, although the liver tissue is friable and the capsule thin and not easily sutured, the bleeding is readily arrested by pressure, and it is possible to remove both simple and malignant tumours if localized and not too extensive.

The relief or cure of ascites dependent on cirrhosis of the liver is quite a different problem. In 1872 I made a Москов operation, due to Dr. Drummond and Mr. Rutherford Morison, who conceived the idea of establishing a collateral circulation by stitching the omentum to the abdominal parietes. The number of cases operated on has been small, and Morison's operation has undoubtedly saved life, and, among others, I can point to a patient who is now well and free from dropsy for whom I operated two years ago.

The surgery of the stomach is still more recent than that of the gall-bladder; but, unlike gall-bladder work, which was successful from the outset, the way to success in gastric operations has been paved with many failures, and only it recently has the stomach come to show what can be done in this branch of work. I am firmly convinced that many deaths are ascribed to cancer when the disease is inflammatory and perfectly curable by the operation of gastro-enterostomy without removal of the tumour; this I can prove from my own experience in patients now living and well several years after an operation which at the time was thought of a palliative time.

Until quite recently gastric ulcer, except for one or two of its complications, has been considered to be a subject for medical treatment from first to last. The profession is, however, becoming awakened to the fact that it is not the trifling condition it was once thought to be, and that it should from the first be taken seriously, for it is in the early stages that medical treatment can be employed to the best advantage, and in the later
stages that general treatment is so often followed by relapse or by serious complications.

I had practically received no attention, from a surgical point of view, up to Senn's classical experimental work in 1886. Acute pancreatitis is, however, one of the most serious and fatal of diseases, often coming on with startling suddenness, and it is astonishing what can have been interfered with before the notification of pathologists until so recently. Fortunately surgery has been able to interfere beneficially in some of these cases, especially those ending in suppuration, and as our knowledge of the subject increases we shall be able to do more both in the way of prevention and cure.

Chronic pancreatitis, though recognised from a pathological point of view, was practically unrecognised as a surgical condition until I drew attention, in June, 1900, to the fact derived from my experience extending over some years, that many cases described as cancer of the head of the pancreas and leading to chronic jaundice, which ended fatally, were really cases of chronic pancreatitis that could be cured by draining the pancreatic duct indirectly through the bile passages; this has led to great success in the treatment of a class of cases previously treated as hopeless.

The treatment of cancer of the pancreas is very unsatisfactory, and whether we shall ever be able to do much for malignant disease in this situation the future alone will prove. The treatment of cysts is much, though it is now established that in drainage we may reasonably expect to cure or materially relieve in a very large proportion (probably 93 to 95 per cent.) of cases.

Calculation of the pancreas is a disease about which very little has been heard and still less done, but of which more will be recorded in the future. The more complete exposure of the pancreas which can now be obtained by the method I have suggested for exposure of the duct will impel us to generalise pancreatography, and will render the operative technique both easier, safer, and more certain.

Tuberculous Disease.—The advances in the pathology and treatment of phthisis since the discovery of tubercle bacilli have become public knowledge, but I do not think it is quite realised how enormous the saving of life has been; for, while in 1838 38 persons in 10,000 died of phthisis, the proportion is now but 13 in 10,000. Obviously, I need only call attention to the fact that as it concerns the abdomen, and, just as we saw that so-called acute peritonitis may be better described as an acute peritoneal infection, so in the case of chronic tuberculosis of the peritoneum, we may be better to term it tuberculous infection of the peritoneum, for it is generally a secondary infection, and, frequently, as can be proved from actual cases, may be treated in an early stage, which I have found to be the other that bears a tuberculous appendix, a tuberculous pyosalpinx or ovary, a tuberculous mass of intestine or mesenteric glands.

What we must do in the future is to prevent these diseases, if we can, by avoiding the distribution of tubercle bacilli in the air and in our food; or, failing that, we must, if possible, catch cases at an earlier stage, and remove the primary focus, so as to prevent the generalisation of the peritonitis to which I have just referred.

The surgery of the intestines provides the most varied and difficult field of work in the abdomen, and, as the ordinary methods adopted in general surgery here need modification, the evolution of intestinal surgery has been accompanied by infinite variety in detail. Cases of tumour of the bowel, when I was a student, were given as a demonstration, though they had been performed as a means of giving relief, which was, of course, merely temporary. At the present time such growths are removed before the supravention of obstruction, and with very good results, both immediate and remote; for instance, my colleague, Mr. H. Littlewood, recently reported a series of 14 colectomies with 10 recoveries, and out of 38 enterectomies which I have performed 20 have recovered, but out of my last 10 in private 15 recovered, showing the progress that has been made in the operative technique.

For the rational treatment of intestinal obstruction we owe much, first, to the anatomical researches of Sir Frederick Treves, and, secondly, to his admirable work on the pathology and surgery of the subject. At the present day the differential diagnosis has been so well worked out, and the technique of operative work so much improved, that no physician or surgeon long delays, if relief be not soon obtained, and the results, as shown by numerous reports, amply justify the change.

What we want to impress on the public is that a radical cure performed early, when it is practically devoid of risk.

Where the radical cure has not been done and strangulation unfortunately occurs, it ought to be more fully grasped that no time should be lost in taxis, but that operation should be performed, when it can be done with a risk of not more than 5 per cent., and radical cure can at the same time be performed.

Among the great advances in surgery in the period in question has been the successful treatment of many of the anomalies of pregnancy; for instance, the eminently satisfactory results now obtained in that ancient operation Cæsarian section. I know of no operation that has given greater satisfaction than this one, for the patients are eternally grateful, which is truly the highest reward of the surgeon.

Ectopic gestation until recently constituted a dark chapter in medicine; it was altogether misunderstood as to cause, pathognomonic symptoms, and hundreds of lives were lost annually which are now saved by timely surgical intervention. To the genius of Lawson Tait, who utilised the post-mortem experience of Bernouts and Godet in 1885, and the clinical observations of J. S. Parry, we owe the successful treatment of this otherwise fatal disease. His work on this subject alone should be sufficient to establish a claim for him to be placed among the benefactors of science and of humanity. The subject is replete with interest, and it may be said without any fear of contradiction that this operation alone has saved thousands of lives which, without it, would have been sacrificed, and probably certified as having died from internal haemorrhage.

The Surgery of the Kidneys and Ureters.—In 1868, Mr. Henry Morris was able to report 34 nephro-lithotomies. In 1886, Mr. Geo. M. Harris had 33 recoveries with 11 recoveries. The operation was performed as a means of giving relief and removing the invalidity of the condition which had taken place. The operation was performed as a means of giving relief and removal of the invalidity of the condition which had taken place. The operation was performed as a means of giving relief and removal of the invalidity of the condition which had taken place. The operation was performed as a means of giving relief and removal of the invalidity of the condition which had taken place. The operation was performed as a means of giving relief and removal of the invalidity of the condition which had taken place. The operation was performed as a means of giving relief and removal of the invalidity of the condition which had taken place. The operation was performed as a means of giving relief and removal of the invalidity of the condition which had taken place.
renal puncture or incision in certain cases of chronic albuminuria; but to Dr. Edebohl, of New York, must be given the credit of adopting an original operation for the treatment of Bright’s disease. As yet it is too early to pronounce a definite opinion on the procedure, but it is an undoubted fact that decapsulation does effect some improvement in this serious malady, and it may possibly prove effectual in saving life in those terrible cases where an impression of urine comes on after some trifling operation, such as catheterism, or after a chill, or in scarlatina.

Ureterotomy for stricture and valvular obstruction, leading to hydropnephrosis, was an innovation first successfully performed by the latter Mr. Darling, of Chicago, in 1862, and since done by others. I find that I have operated on the kidneys 130 times, with 122 recoveries; but 5 out of the 8 fatalities were in my first 18 cases before 1862, 2 being from nephrectomy, and from nephroscopy; this leaves 112 cases since 1862, with 3 deaths, or a mortality of 2.6 per cent. As the series includes cases of nephrectomy, nephroscopy, nephrolithotomy, and nephropathy, it serves to show the greater safety of these operations within the last ten years.

Although abdominal surgery in its widest sense has practically entered into being and developed within the last third of a century, something more than merely crossing the threshold has been accomplished, though very much still remains to be done. It is reasonable to hope that before another decade has passed that great scourge of mankind, cancer, will have been hunted to its source, and then we may reasonably expect the discovery of a means of cure; but as yet, let us confess it plainly, we know nothing of its pathology and can only recommend its removal as soon as discovered, for if it be discovered early and removed freely, surgery can undoubtedly cure a fair proportion of cases and give relief and respite in many more. I look forward to the time when we shall discover the antitoxin and, either by an antitoxin or by some form of serumotherapy, we shall be able to prevent or cure the disease; then, instead of the aid of surgery, the sufferer will have to look to the help of the pathologist and physician.

Of the treatment of streptococcus infection, such as erysipelas and other diffuse inflammations, by the antistreptococcus serum, we can probably all point to some results, as well as to other uncertain results; but as improvement in the preparation of the antitoxin occurs, and as our knowledge of when and how to use it is increased, we shall be able to calculate on many more certain results. At the present time surgeons are finding the injection of the serum of service in immunising before operating in certain regions, such as the tongue, mouth, throat, and rectum, where sepsis cannot be secured with certainty.

ON

INFECTIVE AND INFECTIOUS
DISEASES. (a)

By FREDERICK T. ROBERTS, M.D., B.Sc.,
F.R.C.P.Lond., and Censor.
Senior Physician to University College Hospital and Holme Professor of Clinical Medicine, University College, London.

While the pathological factor or factors which directly originate a particular disease or group of diseases, about which there had previously been but vague theories and hypotheses, have been definitely recognised, and their true nature established, we may claim that a distinct and important advance in knowledge has been gained. It must be clearly understood that according to this definition the term “infective” is not synonymous with “infectious,” which implies that a complaint is capable of being communicated, either by direct inoculation or by contagion, in various ways, from person to person, or from some other animal to man. In short, an infectious disease must be infective; but an infective complaint is not necessarily infectious.

I now proceed to deal briefly with certain points relating to what I may term the practical etiology of infectious diseases, which have been derived from the point of view of practical etiology whether a particular disease is infectious, in the true sense of the term, or not? Next, it is very desirable, with regard to individual diseases, to have as definite a knowledge as possible concerning its period of incubation; the degree of infectiousness; and the period of infectivity, that is how long infection lasts in a particular case? In relation to many of the best known affections belonging to this group, these points have now been established fairly accurately, but there is still much to be done in this direction. As regards the degree of infectiousness, undoubtedly the gradations in this respect between different diseases are by no means so clearly recognised as they ought to be, even by the profession sometimes, but more especially by the laity, and consequently one cannot help being struck with the want of proportion and tendency to exaggeration exhibited in the way in which certain of these complaints are dealt with. For instance, phthisis is really nowadays looked upon as the large majority of persons as if it were a more virulent infectious disease, such as small-pox or scarlet fever, which is of course absurd, but the idea has none the less got a firm grasp, and is doing an infinite deal of serious harm in different ways.

Passing now to the more practical results of modern investigations as to infection, the following facts are worthy of special attention:—

1. As a starting point infective micro-organisms have been found and demonstrated in the blood; in certain secretions; in the excreta, urine as well as faces; in the cutaneous structures or shed epithelium; possibly in the expired air; and in specific lesions, and in the discharges from the same of various kinds. Hence we can readily understand how and why most of the diseases with which these organisms are associated are likely to be transmitted from individual to individual; how the infected materials may contaminate fomites, and be thus conveyed far and wide; how they retain their activity in a dried state for an indefinite period, thus rendering apartments or other places infectious; and how they may be conveyed in the atmospheric currents or winds, and afterwards either inhaled or swallowed by persons, it may be, far removed from the original source of infection, remote epidemics being thus started.

2. The communicability of certain grave diseases by the contamination of drinking water in different ways, but especially by admixture of infected excreta, is an established fact the importance and far-reaching consequences of which it is impossible to estimate or realise in any adequate degree. While we are now all so familiar with the dangers of infected water, it required some hard teaching to convince the profession and the laity of its reality, and we ought never to forget the excellent work done by Snow, Beck, Ballard, and other pioneers in relation to this matter. Even at the present time, moreover, my experience has led me to the conclusion that no means always appreciated as they ought to be, and I have met with not a few glaring instances of the injurious effects of ignorance or carelessness.

3. One of the most striking additions in modern times to our knowledge regarding the conveyance of infection is in relation to food. In this connection milk and its products stand out very prominently, not only on account of their frequent contamination with infectious materials, but by deliberate addition of tainted water to milk, but also because this valuable food may convey organisms directly from diseased animals by whom it is secreted. No list of this kind will be complete without reference to the communicability of bovine tuberculosis to the human subject in this way; but, notwithstanding Koch’s dogmatic negative statement, more recent investigations, prominent amongst them those of
Professor Hamilton, of Aberdeen, and Mr. McLaughlin Young in this country, seem to have demonstrated conclusively that this authority, in spite of his high scientific claims and standing, is entirely wrong. At any rate it would be a grave mistake to act upon the latter’s views, or to ignore in the slightest degree the possibility of the conveyance by milk of the infective agents of tuberculosis or other diseases.

The belief that different animals play in the transmission of infectious diseases to man is another aspect of the subject upon which modern observations and researches have thrown remarkable light. Of course, the relation of such direct transmission as hydrophobia and glanders has long been recognised. The idea of direct infection through the milk of flesh of infected animals is of comparatively recent date. The danger of infection being carried directly by domestic animals, such as birds, cats, and dogs, from person to person, or perhaps because they themselves are suffering from certain diseases, is not yet appreciated as it ought to be. The rôle played by such uninvited "large vermin" as rats and mice in relation to plague, and probably some other complaints, is now familiar to all. Flies, cockroaches, and the smaller but well known personal vermin may no doubt be issued in contaminating infected cases in certain cases, and flies may thus taint food. But the most remarkable and important revelations which modern investigators have given us is the transmission of infection by animals is those relating to mosquitoes and ticks. The close association and demonstration of the transmission between these minute torturers of humanity and malaria, in which Sir Patrick Manson and Major Ross have taken such a prominent part, has already worked incalculable good, and promises in the future to revolutionise the conditions of life in many parts of the world, to the inestimable advantage of the communities who are native to the district, as well as of Europeans from circumstances compelled to go there.

The statement that yellow fever, and probably to other affections prevailing in climates and localities where mosquitos abound.

5. The question of the relation of infection to soil, place, and particular houses or groups of houses, is a very important one, but about which there is at present much that is uncertain and indefinite, and that needs to be worked out more fully before any positive conclusions can be arrived at with regard to individual diseases. The fact that the tetanus bacillus comes from the soil, being especially associated with garden earth, or horse-dung, is well established, and was a most interesting and important modern discovery. But to be regarded by Manson as a "place disease," due to a toxin produced by a living germ operating in some culture medium outside the body. Of course, houses or rooms may, when once infected with the organism, become a "reservoir" of the disease, remain indefinite, and thus be the means of originating similar affections after long intervals.

6. Another most important aspect of infection, from a practical point of view, is the fact that we are always one of us always carrying about in various parts of our bodies microbes which, while habitually innocuous and non-virulent, may under favouring conditions, if so far as they are concerned, become extremely virulent, or possibly specific, to one personal organism; or we may even be harbouring in our mouths, throats, noses, ears, and thereabouts specific germs by which, quite unintentionally, we are liable to infect others at any time, while we ourselves go scot free. It is the fact that these germs or, through germs may lie dormant for an indefinite period in the human body, such as the bacilli of diphtheria, influenza, or tubercle, or their spores, and either lead to unexpected auto-infection, or to the production in other situations of the disease after a long interval.

When suppuration is set up in any part of the body, moreover, it is wonderful how disagreeable the different organisms can be, in the way of migrating to various other structures and producing a similar condition in connection with them.

7. I must just refer, lastly, to the progress made in our knowledge of the channels of entrance of microbes into the system, and the modes in which they are disseminated. Here again the mouth, throat and neighbouring parts come into unpleasant prominence, especially the tonsils, in connection with the throat and laryngeal region; the nasopharynx, the tonsils, with the adenitis, inflammation of the tonsils, adenitis, the adenitis of the throat, and adenitis of the sinuses; with the adenitis of the larynx, and adenitis of the nasopharynx.

Clinical History and Phenomena—Diagnosis.—While we have to record certain distinct advances in the clinical history of infectious diseases, the methods of diagnosis have been of great importance in the infective diseases and the means of diagnosis, progress in this direction has not been anything like commensurate with that relating to their pathology and etiology. We must, as a matter of general principle, rely, and can safely rely on the diagnosis of a particular infectious disease, as regards its actual clinical history, on its mode of onset or invasion, its course of progress, and the simpler phenomena which personally I always speak of as "symptoms," as distinguished from those revealed by skilled physical or other special methods of investigation. And, in my opinion, it would be a serious mistake to encourage in any way the idea that the ordinary routine of this diagnosis and study we cannot come to any definite conclusion except with the aid of modern scientific methods.

There are certain general symptoms which, in a large proportion of infectious and infective diseases, cases, demand the consideration of the connexion between these minute torturers of humanity and malaria, in which Sir Patrick Manson and Major Ross have taken such a prominent part, has already worked incalculable good, and promises in the future to revolutionise the conditions of life in many parts of the world, to the inestimable advantage of the communities who are native to the district, as well as of Europeans from circumstances compelled to go there. The statement that yellow fever, and probably to other affections prevailing in climates and localities where mosquitos abound.

The symptomatic aspect of infectious diseases is of fundamental and essential importance in the ordinary run of cases, but notwithstanding the progress made in scientific clinical methods I must enter a protest against the tendency among the rising generations of our profession, which is quite impossible to overlook, to discard use of the tongue," and "takes the temperature." In some instances both the pulse and the tongue afford special information; but I am not at all sure that this fact is always duly appreciated nowadays. For in connexion one can scarcely avert making some allusion to the "clinical thermometer." This small instrument, I need hardly remind you, at present universally recognised as an invaluable and often essential aid in diagnosis in most infective diseases, not only in determining the existence of pyrexia, but also in studying its degree, course, and other details.

The symptomatic aspect of infectious diseases is of fundamental and essential importance in the ordinary run of cases, but notwithstanding the progress made in scientific clinical methods I must enter a protest against the tendency among the rising generations of our profession, which is quite impossible to overlook, to discard use of the tongue," and "takes the temperature." In some instances both the pulse and the tongue afford special information; but I am not at all sure that this fact is always duly appreciated nowadays. For in connexion one can scarcely avert making some allusion to the "clinical thermometer." This small instrument, I need hardly remind you, at present universally recognised as an invaluable and often essential aid in diagnosis in most infective diseases, not only in determining the existence of pyrexia, but also in studying its degree, course, and other details.
as it might be in other complaints of an infectious nature.

The special methods of diagnosis applicable to infective and infectious diseases which modern scientific researches have brought so prominently before the medical profession have naturally attracted great attention and excited keen interest. I must content myself with merely giving the following summary of these methods and their objects, mainly coming under the head of bacteriological diagnosis.

They include:

1. Examination of the blood, both as regards its normal constituents, especially the number of leucocytes and the relative proportion of different kinds of cells, the blood plates, and the presence of abnormal corpuscles; and from a bacteriological point of view, the bacillus of relapsing fever and the malaria parasites are prominent examples of pathogenic organisms found in the blood, and the latter have to be observed and studied during the changes they undergo, along with their effects upon the red corpuscles and the formation of pigment.

2. The further detection and microscopic demonstration of organisms, specific or non-specific, or both, either obtained from the tissues of the body or contained in secretions, faces and urine, various discharges, sputum being particularly noteworthy, and other morbid products of different kinds, fluid or solid, of which diphtheritic material is a conspicuous example. These organisms are not only identified by their morphological characters, but also, as a rule, by their peculiar staining reactions.

3. Separation or isolation of the microbes, which are afterwards grown on suitable media, in order to obtain cultures, the results being often highly characteristic, both to the naked eye and on microscopic examination.

4. Application of the "segregation" and "agglutination" tests, in relation to blood serum of the patient, which is most familiar to us in Widal's test for enteric fever.

5. The observation of the effects on the individual of the inoculation of certain products of the specific microbe of the disease from which he is supposed to be suffering, as in the so-called "reaction test" with tuberculin for tuberculosis.

6. The pathological results of inoculation of animals, either the organism itself in those cases or with their toxins, which in some instances are essential for positive and accurate diagnosis, lesions of a definite and characteristic nature being thus produced, as in the frog by diphtheria.

A rather awkward question, but one of extreme practical importance to the profession, has been recently forced upon our notice, which I cannot altogether pass by, viz., the numbers of cases of mistaken diagnosis sent to the Asylums Board's hospitals as notifiable. Of course, any carelessness in diagnosis in relation to infectious diseases is inexcusable; but really young practitioners are not responsible for the fact that they are not so familiar with these complaints clinically as would be desirable, and that many of them have to gain the requisite experience after they have entered upon their active professional duties. May I venture to say that while the modern medical student has immense advantages, he labours under a decided disadvantage from this point of view, as compared with those of us who served an apprenticeship, and became familiar with at any rate the more common infectious diseases, even before we started upon our regular studies at a medical school. As a matter of fact he gets very little opportunity of gaining practical knowledge of most of these complaints during his period of probation, and he will back up what is called "post-graduate instruction" if he desires further and more special training and experience. The bacteriological methods of diagnosis ought to help materially, should there be any difficulty in diagnosing the number of mistaken cases in the future, especially if facilities are afforded to the practitioner of using them without delay; but they are not infallible, even where they can be applied.

TREATMENT AND PREVENTION.—Taking a comprehensive survey of the changes and modifications which have taken place in the treatment of infectious diseases, one of the most remarkable and important is the severe depleting and depressing measures which were formerly extensively, if not almost universally, carried out, have been practically done away with, and are now only resorted to under exceptional circumstances or for particular purposes, as in the free use of purgatives for certain individual complaints. Further, it is a matter of profound congratulation for ourselves and our patients that we now apply physiological, natural, and sanitary principles, in dealing with these diseases as a matter of routine, in the way of physical and mental rest, abundance of fresh air and ventilation, care of the alimentary organs, and surroundings, regulation of diet, personal cleanliness, general comfort, judicious disinfection, and other essential matters. In my opinion a very large proportion of cases of acute specific fevers can be steered through their course on the lines just indicated, without any active treatment whatever, unless it be an occasional apéritif; or, if the exigencies of private practice demand some "medicine," we have excellent remedies such as the "saltpetre," "sulphate of iron," and the "effervescent mixture," which, at any rate, are quite harmless, and may be of definite use for certain purposes. The "open-air" treatment of phthisis is in reality in the main a mere development of similar principles.

Let it not be supposed, however, from what I have just said, that I advocate a general policy of "masterly inactivity" in dealing with infectious diseases. With out entering into any details, I may point out that one of the chief classes of therapeutic agents which in modern times have come to the front in the treatment of infectious diseases are anti-therapeutics, anti-infectives, germicides, or better, as they are now called, to which group not only many valuable additions have been and are being made, but which are now employed in ways which our predecessors never dreamt of, though I think that some of the methods of using or administering certain antiseptics in relation to particular diseases which are advocated and practised at the present day are decidedly open to criticism. Another remarkable group are the new hypnotics prepared in the chemist's, the phenozyne acetanilide, phenacetin, &c.—which, when judiciously given, may be of conspicuous service. Other agents deserving of mention are cardiac stimulants and tonics, strychnine having not unfrequently been a most valuable remedy from this point of view; and the newer hypnotics or other drugs intended to relieve particular symptoms, which may thus afford material assistance in guiding patients through serious illnesses of this nature. In this connection I may also mention certain therapeutic methods and agents, of comparatively modern introduction, which are undoubtedly of conspicuous service in combating grave conditions immediately threatening life, such as subcutaneous intravenous injection of ether or other diffuse stimulants, inhalation of oxygen, saline injections, and transfusion of blood or other suitable substitutes. For the various contagious diseases, as we so often have to deal in relation to infectious diseases, and which not uncommonly sorely perplex us, treatment must be conducted on general principles, guided by the knowledge, experience, and common sense of the practitioner.

There are certain special questions bearing upon the treatment of infectious diseases which I cannot pass over on an occasion like this without brief comment, regarding hydrotherapy and allied nostrums. In the treatment of infectious diseases, I would remark that every medical practitioner ought to be familiar with them, and be able and ready to carry them out when necessary. The mildest methods, such as sponging the skin or applying ice locally, are easily practised, and are often of the greatest service. Personally, however, I do not advocate or employ the more severe methods as a routine system, as many do; and I feel sure that
I have met with serious injurious consequences from such a practice. On the other hand, their essential value in saving life under such grave conditions cannot be over emphasized, and it is incumbent on the practitioner to guard against their use indiscriminately.

With regard to the administration of alcohol, I feel bound to take this opportunity of stating emphatically that when we, as members of the medical profession, allow ourselves to be led by the cry of, "Do you medicine when the patient is thirsty?" and so forth, as a question, we ought to do so under a deep sense of responsibility, but at the same time rationally and without undue bias one way or the other. The medical profession as a body is bound to sympathise with any efforts, and efforts made in this country to check the terrible evils produced by intemperance, which confront us in such an overwhelming and appalling degree on all hands in our daily experience, and to do our utmost to promote sobriety among all classes, however hopeless the task may appear to be. And from this point of view we should always be most careful to avoid offering stimulants to patients not accustomed to them, unless they are, in our individual opinion, really necessary; while it is well always to give definite instructions as to their administration.

At any rate, so far as infectious diseases are concerned, I must express my strong anxiety that the large number of cases the judicious administration of alcohol is of the greatest service, and I have seen a considerable number of grave and sometimes hopeless cases in which I have no hesitation in affirming that recovery was due to the use of alcoholic stimulants, and not unconnectedly in considerable quantities. Moreover, they are often of conspicuous value during convalescence.

What would, no doubt, be generally regarded as the most vitally interesting and important question of modern times, bearing upon the prevention and treatment of the entire group of infective diseases, is that of "serum therapy," using the term as an inclusive one which has come to the natural outcome of the microbic theory, and is founded, on the whole, on reliable bacteriological researches and experiments, supported by the results of practical experience in living subjects. Following Sims Woodhead's classification, the materials used are divided into—(1) Vaccines, which are either cultivations containing pathogenetic microorganisms with toxins, or toxins only; or the tissues or fluids of an animal suffering from a particular infectious disease; (2) Antisera, which may be antigenic only, neutralising the toxins; antibacterial or antimicrobial, acting directly upon the organisms; or in some instances having the effects of repeated injections of this substance in rendering the blood serum of an animal both antitoxic and bactericidal.

In the diagnosis, prognosis, and treatment of pulmonary tuberculosis much reliance has been placed on the results of a systematic, periodical registration of the temperature. Unfortunately for long there have been wide differences in the methods employed for taking temperatures. With the springing up of sanatoria in various parts of the country, in which temperatures are taken as one of the important guides in the modern hygienic treatment of these cases, it seems advisable that there should be less divergence in the methods of registration not only in the interests of the patients themselves but also for the sake of scientific medicine.

Since comparatively few observations have been published in this country with the exception of the recent papers by Mr. J. C. Braine-Hartnell, and Drs. F. W. Burton-Fanning and S. G. Champion, (2) on the results of a systematic registration and comparison in the same case and at the same time of rectal and oral temperatures, we propose to briefly summarise our recent observations on oral and rectal temperatures, and to indicate what we consider to be their respective advantages and disadvantages.

Our conclusions are based on 17,440 individual observations.

(1) Substance of a paper presented to the Medical Section of the Seventy-first Annual Meeting of the British Medical Association at Liverpool, July 24th, 1902.
(3) Burton-Fanning F. W., and Champion, S. Gurney, "The Comparative Value of the Mouth, the Rectum, the Urine, the Axilla and the Groin for the Observation of the Temperature." The Lancet, London, March 26th, 1908.
observations in 300 different patients, in all stages and of every variety of tuberculous disease of the lungs.

It should at once be clearly understood that in many of the statements hitherto made in regard to this matter, sufficient attention has not been drawn to the variations in the temperature of the mouth and rectum brought about by varying degrees of exercise.

In a healthy adult, during rest, the rectal temperature is normally a little less than 98.5°F. higher that of the oral method.

It is clear that most forms of exercise necessarily entail a certain degree of exposure of the mouth, which, of course, tends to give a lower thermometric reading than that of the protected rectum. It may here be noted that the oral temperature is not infrequently distinctly raised by exercise even when such is physiological rise without undue exposure of the face and mouth to cold air or winds or other influences tending to lower its temperature.

In a healthy adult, in fair training, after exercise the rectal temperature is raised from 2°F. to 3°F. In the case of one of us, after an hour’s lawn tennis the rectal temperature rose from 98°F. to 101°F. while at the same time the oral temperature passed from 98°F. to 98°F. Similar results were obtained on subsequent occasions.

From the above consideration it is manifest that in diseases states the normal physiological variation in the temperature as taken in the rectum during exercise and rest must not be overlooked.

In some institutions, we understand, great importance is placed upon the rectal temperature taken during or immediately after exercise; and greater stress is laid upon its directing value by some than when taken during rest. In such procedure, it seems to us, sufficient allowance is not made for the physiological rise directly dependent upon recent exercise, and not necessarily indicative of any pathological condition.

In the healthy adult this rise is but of short duration, whereas it is claimed that in the tuberculous the elevation is maintained for some time; but, even allowing for this, we are of opinion that as a general guide to the diagnosis and treatment of conditions the temperature records taken during rest are of greater importance and afford much more reliable indications for treatment than does the rapidly altering pyrexia dependent on exercise.

We may here add that at the Mount Vernon Hospital, where our observations have been made, it is customary to depend chiefly on temperatures taken during rest and at least an hour after exercise, and this plan, from an experience of several years, has been shown to afford what we consider the most satisfactory indication of progress and reliable guide to exercise and general management of cases.

THE ORAL METHOD OF REGISTERING TEMPERATURE.

The advantages of the oral method are generally recognised to be its simplicity of application, its cleanliness, and that it has for long been in vogue since most of our best available data respecting tuberculous temperatures are based on readings taken in the mouth.

Whatver method is shown to be the most suitable for phthisis may also be expected to prove most desirable for the registration of "surgical" and other forms of tuberculosis and pyrexial diseases generally if reliable comparisons are to be made.

The chief disadvantage said to be associated with the oral method is that it is unreliable.

It is claimed that exposure of the face in the open, the imbibition of drinks, engaging in conversation, active exercise and the like, lower the temperature of the buccal cavity below that of the body generally.

It is, moreover, said that even with a quick registering thermometer a considerable time (some say 30 minutes) is required to get the maximum record. A consideration of the conditions under which it is customary to take oral temperatures will show that many of the above objections are mainly theoretical.

It may be added, however, that reliable "rest" oral temperatures can be obtained with much greater rapidity than during or after exercise, and it must be admitted that under conditions usually associated with the latter some difficulty may be experienced in obtaining a reliable reading in the mouth.

THE RECTAL METHOD OF REGISTERING TEMPERATURE.

The advantage claimed for the rectal method of recording temperature is that it is more reliable since it is less susceptible to varying extraneous influences.

In 11.3 per cent. of our observations the rectal reading maintained a more regular range than the oral, and, taken into consideration along with the condition of the patient, was considered to afford the best guide to management.

The disadvantages of the rectal method, particularly when taken after exercise have been already alluded to. Whilst some patients do at first object to the procedure, any aesthetic objection may generally be readily overcome by a tactful physician if the advantages can be shown to be sufficiently real. A reference to our observations may here be made as indicating the relative value of oral and rectal temperatures.

In 45 per cent. of our cases the rectal temperature closely corresponded with the oral, being from 98°F. to 1°F. higher.

In 38 per cent. of our cases the rectal temperature bore no constant relation to the oral, being sometimes higher and frequently lower. Most of these cases were subacute or had only a slight degree of pyrexia; and here it may be added that, generally speaking, the discrepancies between oral and rectal temperatures have been most apparent in patients with a comparatively slight degree of pyrexia, whilst, on the other hand, the oral and rectal have more closely corresponded when a conspicuous and persistent degree of pyrexia has existed.

In 43 per cent. of our cases the rectal temperature appeared to be very misleading, being constantly below the oral. Thus in one case of extensive laryngeal ulceration and miliary outbreak in the lungs the rectal temperature was almost constantly 2°F. below the oral. The remaining cases in this group were also active, and the rectal temperature remained constantly below the oral in each case for four weeks.

CONCLUSIONS.

1. Temperatures carefully taken in the mouth during rest form a reliable guide in the management of phthisical cases under conditions of sanatorium life.

2. Temperatures taken in the mouth during or shortly after exercise cannot be considered trust-
worthy unless registered with such precautions as mitigate against their general applicability.
3. Temperatures taken in the rectum during rest, generally speaking, register higher than in the mouth, but do not otherwise usually afford any special assistance in the management of phthisical cases.
4. Temperatures taken in the rectum during or shortly after exercise in both healthy and phthisical subjects register a temperature considerably higher than that in the mouth; and, whilst in the non-tuberculous the return to normal is more rapid than in the tuberculous, no special directing advantage in the treatment of the phthisical appears specially to accrue from this method.
5. For practical purposes, in the management of phthisical cases undergoing so-called sanatorium treatment, the registration of temperature by the oral method, when taken during rest and with due care affords reliable guidance.

ATROPHIC CORYZA: ITS DIAGNOSIS AND TREATMENT. (a)

By Dr. E. J. MOURE, Bordeaux.

[Specially reported for THE MEDICAL PRESS and CIRCULAR.]

I PROPOSE to pass in review the numerous clinical varieties of atrophic coryza, an affection on which specialists are not always in accord: one which has been the fruitful source of discussion in every country in the world. Rhinologists designate the disease by the titles of ozéna, true ozéna, or simple atrophic ozéna. These names are misleading, for we meet with ozéna without atrophy and atrophy without ozéna. The name ozénic rhinitis, although more exact, does not fully express the condition we are here considering—the acute period of the disease, when the secretion is very abundant and prevalent, with a tendency to accumulate in the nasal fossae and to decompose there. When the pathological process has proceeded to the total destruction of the glands and soft tissues and broken down the osseous structures, the ozéna disappears, and the ordinary nomenclature becomes misleading. Again, it is undeniable that certain forms of coryza of the atrophic variety, though they have a copious purulent secretion, never develop a fistulsmell, the odour being no more disagreeable. In this stage the membranes are swollen, the hypertrophic state of some authors. The conditions are not, however, accurately described by the name atrophic coryza.

In these latter years some practitioners, Grünwald especially, admit that ozéna has its origin in the nasal sinuses; but they add that it is not always possible to detect the site. Now we hold that owing to the facility the nasal sinuses offer for examination the site of the beginning suppuration can be always detected. The many different views held on the pathology of the disease may be ascribed not only to the many clinical varieties that present themselves for examination, but also to the various periods of the disease, the age of the patient, and so forth.

It is plain that atrophic coryza seen in the young adult, in the man of middle life, and in the aged does not offer the same resistance to treatment. Trousseau drew attention to the fact that in advanced life when the nasal cavities are enlarged

(a) Read before the International Congress at Madrid, April, 1903.
in other regions of the body. Lastly, in the true atrophic ozena, of Martin, with all ozenas of infancy lavage is to be regularly practised, until the child outgrows the allowances of more severe treatment, that is, until it reaches six, eight, or ten years of age. Then we should endeavour to restore the processes of the turbinate bones, which have decayed by interstitial injections of paraffin, which I have practised for years, as have my colleagues. Without doubt this treatment is most valuable in both stages, the sequestering and getting rid of the fester. In the use of the interstitial injections of paraffin in my clinic Dr. Brindel and I have devised a technique which on a future occasion we hope to bring before you. I may just say that the treatment follows the natural lines in restoring the lost parts, and by distending the nasal membrane gets rid of the aprons of tissue which form sacculles and so retain the fetid crusts—inspissated purulent matter. The use of paraffin in these cases is the carrying out in practice of the theory of Zaufel. I took on this method of treatment by paraffin as an undoubted improvement, a step forward which should give successful results. It is a happy application of the method of various, and of, d’Erkstein, of the treatment of an intractable disease, one that the majority of rhinologists consider incurable.

The Out-Patient Departments.

SAMARITAN FREE HOSPITAL.

Tubal Pregnancy developing under observation, and diagnosed before Rupture.

Under the care of Mr. W. Sampson Handley, M.S.

R. N., aged 35, attended the Samaritan Hospital on June 6th, 1901. She had been married five years. There was one child, born in 1897. The confinement was normal, and there has been no miscarriage at any time. Menstruation began at seventeen, comes on every four weeks, lasts six days, and is sometimes profuse. It is accompanied by considerable pain in the hypogastric and sacral regions. The last period was a week ago. She complained of hypogastric pain, dating back two years, and more or less constant. The pain is not worse during micturition, and has no relation to intercourse. She has a regular bowel motion. The bowels are regular. The pelvic organs appeared to be normal; there was no lump near the uterus-unilocular. Mist. tinct. c. rheo. was ordered. There was some doubt as to the patient's habits with regard to alcohol. On August 1st she reported that the courses were a fortnight overdue. The nipples were sore, the breasts painful, and occasional morning sickness had occurred. The voice was not softened. The uterus was firm and somewhat enlarged, and a doubtful small lump was indistinctly felt to the right of the uterus. On August 8th the patient had a large loss of blood, with clots and fleshly pieces; she fainted two or three times. On the right side particularly, it occurred as in the palm of the hand. From this date (August 8th) the breasts have become smaller and less painful. On August 12th, when she was seen, there was no milk in the breast. There was a large amount of blood-stained discharge from the vagina. The uterus was movable and decidedly enlarged, reaching to the level of the pubes. To the left of the uterus was a very definite, tender, rounded movable lump, displacing the uterus slightly to the right. The uterus was firm, was not tender, and had not the characters of the pregnant uterus. A diagnosis of tubal mole was made, the involution of the mole apparently indicating death in the fetus. As the hospital was on the point of closing for the summer vacation there was no choice but to send the patient home to bed. The nature of the case was explained to her, and she was told to seek help at once if severe pain or bleeding supervened. Small doses of bromide were given.

On September 19th, she came up again, still with hypogastric pain and bright blood-stained vaginal discharge. The uterus was slightly retroverted, and the lump slightly in front of it, as well as to the left. On October 6th the lump was observed, if anything, rather smaller, but symptoms still persisted, and an operation appeared unavoidable. The hospital being now reopened, she was admitted under one of my colleagues, who removed by colpotomy an unruptured left tubal mole. On the right side there was a small hydrocele. The patient made a good recovery.

In this case the evidence of death of the fetus, combined with the absence of severe pain and of serious bleeding, seemed to justify, if not to demand, expectant treatment. Even in so favourable a case as this, however, operation became necessary, and in any similar future case I should advise operation, unless the pain and bleeding completely ceased after a fortnight's rest in bed.

The main lesson of the case is that a thorough pelvic examination should be made in every case of supposed complete or incomplete abortion. If a lump is found near the uterus the possibility of ectopic gestation in one of its less dramatic forms should be carefully considered.

BRITISH SANATORIA FOR CONSUMPTION.—VI.

[By Our Special Medical Commissioner.]

THE OCHIL HILLS SANATORIUM.

The establishment of sanatoria for the hygienic treatment of pulmonary tuberculosis in accordance with the best modern methods has raised many points of considerable ethical as well as financial interest. It is perfectly true that in many quarters strong objection is felt to the conduct of an institution for the arrest or alleviation of disease by organised financial combinations of a more or less private nature. No doubt a painful and blighting sanatorium presents many advantages, at least judged from a theoretical standpoint, but since the expense of founding and maintaining an adequately equipped institution suitable for the effective treatment of consumptives is beyond the means of most private individuals, it becomes necessary in some instances to carry on the work by an association which cannot well be other than on "business lines." It is, however, most desirable that these institutions should be saved from any impairment of usefulness by a charge that they are "run to pay." In all cases absolute honesty must prove the best policy, and the interests of the patients must ever have the first consideration.

This leads us to point out that the sanatorium we are about to describe is the result of combined business action; in short, that it is conducted by a small limited liability company.

The Ochil Hills Sanatorium, Kinross-shire, Scotland, has been built at a cost of £40,000, and is one of the most imposing of recent British institutions for consumption. On the north-east the land rises to 1,050 feet, and on all other sides there is ample protection, and the front of the sanatorium is wholly exposed to the south. The views from the lightly rising gradients are particularly fine, including Loch Leven, the Grampians, the Lomonds, the Pentlands, and the Valley of the Forth. Many places of great natural beauty and historical interest are within walking or driving distance.

Unlike many recently constructed buildings for consumptives, the Ochil Hills Sanatorium has an imposing aspect, and being well-built of stone,
presents a very substantial appearance. Indeed, for many miles it appears as the most conspicuous object in the landscape.

There is accommodation for 60 cases. Each patient has a bedroom with a southern aspect. The rooms are well-constructed and suitably furnished. The patient and the comfort and convenience of all patients seem to have been considered with elaborate care; indeed, there seems a danger that the luxurious attractions of the building itself may tempt cases to neglect the simplicity of outdoor existence.

Very extensive arrangements have been made for the application of hydro-therapeutic measures. Spray, shower and sitz baths are available on each corridor. The buildings throughout are lit by electricity. An elevator is provided for the use of the patients.

The grounds, which are very extensive, extending to 560 acres, are particularly attractive, and well suited to the needs of consumptive patients. Excellent shelters are provided, and a well-placed sun-bath is in course of preparation. The estate possesses many miles of walks of various gradients, amid the shelter of pine trees, and allowing of magnificent views of loch and scenery.

Admirable arrangements exist for the thorough scientific investigation of every case, and the sanatorium is well equipped with all modern requirements for treatment. There is a special inhalation room fitted with electric motor for driving a spray apparatus, a convenient electrical room with elaborate installation including apparatus for radiography, the application of high-frequency currents, and the use of ultra-violet light.

Strict medical supervision is provided. Two medical officers are in constant residence. The senior resident physician, Dr. Thomson Campbell, has enjoyed several years' experience in sanatorium methods. Dr. Duncan and Dr. Donald Fraser attend as visiting physicians, and Mr. Walker Downie, of Glasgow, is the consulting laryngologist.

The inclusive terms for board, medical attendance, and medicine are £5 per week. Such care is exclusive of special nursing, personal laundry, driving and alcoholic liquors.

The sanatorium can be conveniently reached. Kinross Junction or Milnathort Station, the two nearest points of arrival, are on the main line of the North British Railway, within an hour from Edinburgh and a half from Glasgow.

Telephone trunk connection with the sanatorium can be effected with all parts of the country.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, August 2nd, 1903.

SYphilis in the Monkey.

At the meeting of the Académie de Médecine, M. Metchnikoff presented a female chimpanzee on which he inoculated by scarification of the clitoris the scrapings of a chancre; twenty-five days afterwards appeared a small erosion, followed by ganglions in the inguinal regions. Although there had not yet appeared any trace of eruption on the body, the speaker considered that the character of the erosion and the inflammation of the inguinal glands justified him in believing that the inoculation was successful.

M. Fournier said that he had no doubts on the case, yet he thought that it would be well to wait another month to see if the secondary symptoms of syphilitic infection made their appearance. If they were the case new horizons opened out for the treatment of that plague of humanity, as probably a curative serum would be discovered. He had made repeated experiments following his colleague, M. Metchnikoff, but failed each time, and he believed this failure was due to the fact that he had tried them on certain races of monkeys too far removed from man. In any case he paid a high tribute to the scientific researches of the Pasteur Institute, which not only honoured medical science but were also a source of great benefit to humanity.

Phlegmasia alba dolens.

M. Chantemesse, speaking of the quantity of chloride of sodium eliminated by the urine in typhoid fever being less than in the normal state, said that it was thought that the retention was made in the blood, but such was not the case, the salt being retained by the proper cells of the tissue. The proof was easy. If a large dose of salt were administered to a typhoid fever patient the excess was not eliminated by the urine, nor would it be found, by analysis, in the blood; it was absorbed by the organic elements. Everyone knew that phlegmasia alba dolens was a relatively frequent complication of typhoid fever, and was remarkable for its long duration. M. Widal had demonstrated how in patients suffering from Bright's disease, the oedema of the cellular tissue was in proportion to the quantity of salt absorbed by the patient, and that it could be diminished or reproduced by suppressing or administering the salt. The speaker considered that there was a correlation as to cause between the oedema of Bright's disease and phlegmasia dolens of typhoid fever. He had applied the régime of saltless food to six patients suffering from typhoid fever and phlegmasia dolens of one of the inferior extremities, and all of the cases rapidly improved under that treatment and in a very remarkable manner. He believed he was right, consequently, to conclude that the above-named affection appearing in the course of typhoid fever was the result of infection of the limb by the presence of chloride of sodium; the venous obliteraton might be considered as only a predisposing cause.

Germany.

[FROM OUR OWN CORRESPONDENT.]

Berlin, August 1st, 1903.

At the Society für innere Medizin, Hr. Litten related a case of Acute yellow atrophy of the liver, with demonstrations. The patient was a girl, 21 years of healthy parentage. She came to Berlin with a view of preparing for a situation, and brought a medical certificate of health with her. Three weeks ago she made an excursion to Potsdam, along with the other members of the pensionate, which lasted from six in the morning to nine in the evening. There long walks were taken, and in the evening there was dancing, in which the young girl was specially active. The following morning she complained of diarrhoea. The medical man who saw her found no fever, a very slight jaundice, discoloration of the skin, and concluded the illness was an intestinal catarrh with a sort of catarrhal icterus. The following day both diarrhoea and icterus were worse; the patient became very yellow, and on the fifth day was admitted into hospital. The condition on admission was as follows: She was well nourished, with deep yellow coloration of the skin and conjunctiva; the spleen was enlarged; there was a left-sided pleural exudation; 4 per cent. albumin in the urine; yellow-coloured yellow urine; small haemorrhages in the skin; temperature, 35° C.; sensorium free; pale-coloured liquid motions; urine strongly icteric, and the abdomen distended. The
following day the sensorium became affected, and the patient died in a comatose condition. As there was no question of poison the diagnosis lay between acute yellow atrophy of the liver and portal thrombosis. The autopsy declared for the abdomen, and opening the thorax, a small pleuritic effusion was seen on the left, extensive hemorrhages in the pleura, nothing abnormal in heart or lungs. The liver was found to be quite shrunken, very small, weighing only about 870 grms., as against 1,500, the average. The spleen was double the normal size. There was severe catarrh in the large intestine, especially in its lower part, and a bloody swelling of the kidneys. The case was one of old excessive atrophy of the liver, upon which an acute yellow atrophy had developed. For this reason the disease had run so rapid a course that no red atrophy had appeared. The microscope showed that the two diseases had existed side by side, an acute destruction of the liver cells such as the speaker had scarcely ever seen—the liver structure was totally destroyed. There was also newly-formed connective tissue, out of which later liver cells and bile capillaries would develop—therefore, degenerative and regenerative changes hand in hand. It was very remarkable that the strong girl had not shown a single symptom of atrophy of the liver before the fatal illness.

From the spleen cultures were made from which cocci developed, and these on agar gave long chains of streptococci. From these, again, cultures were made in bouillon with which two mice were inoculated. One mouse died in three days (kidney degeneration); the second became ill, but recovered.

Mr. Hollandier showed preparations from a case of

GLOMERULO-NEPHRITIS IN AN INFANT.

The infant, 8 months old, had suffered from haematuria for two months. The medical attendant was doubtful whether the case was one of renal calculus or of Barlow's disease, as the child had been fed on sterilised milk. Whilst the child had suffered in its general condition but little, fever suddenly set in, and pus passed from the bladder. Constipation followed the use of uncooked milk. When the speaker first saw the child the haemorrhages had ceased for a week; it was much reduced, there was pus in the urine, pain noticed about the right kidney, with slight enlargement of it. The cystoscope showed normal urine from the left ureter, whilst that from the right was mixed with blood and pus. There was therefore a right-sided renal tumour, with secondary bacterial infection, or the tumour was on the left, the infection on the right, or kidney disease on both sides with infection of the right, or right-sided kidney disease from the Barlow's disease, of which, besides the haematuria, no other symptoms were present. An operation was performed, and the right kidney extirpated. It was strown through with miliary patches. The fever ceased at once after the operation, and the child had recovered as far as the operation was concerned. It might be accepted that the haematuria was due to Barlow's disease. Microscopically, the disease proved to be glomerulo-nephritis.

ALCOHOL APPLICATIONS EXTERNALLY.

Professor Laszewlowsky, Dorpat (Allg. med. u chir. Zeit. February, 1903), has a paper on this subject. He has been using them for two years in cases of pleurisy, peritonitis, and arthritis. He reports two cases of peritonitis in which the alcohol was applied in the following manner. A soft serviette was folded in four and soaked in alcohol so that nothing dripped from it, and then laid over the abdomen. Slightly moistened parchment paper was then laid over the dressings, the edge being tucked in all round to prevent wetting of the garments. The dressing was renewed as the alcohol evaporated, at first every half-hour, then less frequently, and at last twice in the twenty-four hours. On the second day improvement set in, which ended in recovery. The patient was rather severe, and made worse by weight, so lint was used later in place of the serviette. The lint was covered with parchment paper with holes in, so that the alcohol could be put in afresh without disturbance. A bandage was placed above all The alcohol was introduced into the perforation through a glass funnel. A good deal of alcohol was required, so that it would not be made use of frequently in private practice.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, AUGUST 2nd, 1903.

ARISTOCRIN AND PERTUSIS.

Surodor is attracting attention to aristochin, one of the quinine preparations which has been freely used in Prof. Frühwald's wards with apparently good results in cases of whooping-cough. He relates 69 cases of recurrent paralysis which have been quite restored by the application of the drug. Among these cases were eleven from atheroma of the aorta, and six from aneurysm of the aorta. It seems that the atheroma was directly the cause of this paralysis, and not pressure on the nerve as if from an aneurysm. The same may be said of two cases of aortic insufficiency, and others by stenosis of the mitral valve, carcinoma, mediastinal tumours, pleuritis, and tuberculosis accounted for others of a more serious character.

Frankenberger said that he had seen cases of aortic aneurysm where the Röntgen rays alone could be relied on as diagnostic. A very common cause of recurrent paralysis was syringomyelia.

Thomayer said that recurrent paralysis did not always produce hoarseness, and therefore was not a trustworthy symptom. He recently had a theatrical patient with recurrent paralysis, not from atheroma or any of the usually ascribed causes, but from protruded vocal excretions.

APHASIA.

Heveroch related the history of an unusual case of aphasia to the meeting of Zürse assembled in Prague. On exhibiting the patient, he said his intelligence had begun to wane about four years ago, as well as the power of speech, which was more prominent in the case of answers or explanation. His efforts were often so long continued that different ideas were in the end produced from what he had originally intended. He thought the disease belonged to that group of morbid change usually designated "amnestic aphasia," which is also related to "automania." The original cause, he thought, was due to atrophic or encephalo-malacia in the brain function of speech.

Vitek compared this case to another of transortical motor aphasia of his own, wherein the association communications were involved, leading to the same difficulty with verbs that was present in Heveroch's case. He considered the cause to be one of interruption of the motor centre that isolates the verbs.

XERODERMA PIGMENTOSA.

Samberger exhibited a boy, 13, whose face, neck, hips, and hands were covered with a sort of summer speckled skin with atrophic interspaces, whose vessels were largely dilated. On the lower eyelid there was a patch about the size of a franc piece.
raised, hard and nodular. Other small red tumours were also present.

Along with this case he showed another of folliculitis, or necrotic tuberculides, according to some authors, occurring in a young woman, et. 23. The body and extremities were covered with dark red nodules, varying from the size of a pin's head to that of a lentil, around which were halos of infiltration, vesicles, pustules and ulcers. Some of these had taken on a healing process, leaving a dark pigmented cicatrix. The disease commenced about two years ago. It may be added that wherever any appearance of healing takes place a new eruption appears greater than the original.

CASTRATION.

In a long communication to the "Gesellschaft," Brener and Seiller brought forward a number of very conclusive facts to prove that castration has as marked effects on the male as the removal of the ovaries in the female. The blood which was examined for some time before the castration, was found normal, but immediately after the operation both the quantity of haemoglobin and the number of red blood corpuscles rapidly fell, as in the female when the ovaries are removed. They conclude their argument with the theory that the real genesis of chlorosis is dependent on the ovaries.

In connection with this subject Freud raised a discussion on a different form of iron found in the blood in combination with albuminates, that must be estimated differently to obtain the same result. This new body Seiller is pleased to call "hamatinoegen.

The Operating Theatres.

GUY'S HOSPITAL.

FEMORAL ANEURYSM.—Mr. Arbuthnot Lane operated on a soldier, et. 28, who was suffering from an aneurysm of the common femoral artery, which extended along the upper part of the superficial femoral. Fixed on the surface of the pulsating mass, which was about the size of a large tangerine orange somewhat flattened from before backwards, were a number of enlarged lymphatic glands, and a second series of glands could also be felt. The man denied having had a chancre or any evidence of syphilis, but had had gonorrhoea on two occasions. The history of the swelling was very short; indeed, he said he had only observed it three weeks before. There was no evidence of his having sustained any injury or strain. He had served several years in India. Mr. Lane exposed the external iliac artery, which he ligatured about a finger's breadth above Poupart's ligament. He then exposed the swelling and found the enlarged glands inseparably fixed in its wall. The femoral vein beyond the swelling was blocked with clot; it was matted firmly together with the superficial femoral artery. On laying open the tumour a quantity of firm clot was exposed. Bright red blood welled up continuously, and not intermittently, from the cavity. This was found to emerge from the openings of the profunda and superficial femoral arteries. These were ligatured. The bulk of the sac was then removed and the wound closed, except where a small drain was inserted. Mr. Lane said that in his experience the case was one of considerable rarity. He pointed out that when the student reads his text-books he becomes imbued with the idea that poons abscess, femoral hernia, inflammation of the femoral glands, and aneurysm of the femoral artery are of equally common occurrence, and he is rather surprised to find that aneurysm of the femoral artery is a condition of great rarity, and that he will probably never see a case during his lifetime. In this particular instance, Mr. Lane remarked, the aneurysm must have been developing for a very much longer period than the patient imagined, since the collateral circulation in the arterial and venous systems had been rendered quite perfect that after the operation only a very little transitory edema was observed. The operation was performed by ligaturing and the tenderness which was associated with the inflammation, and enlarged glands which were embedded in the wall of the aneurysm, led many of those who saw the case to believe it was one of an abscess of the femoral glands, the existence of a quantity of firm clot in the sac and the consequent inability to diminish its bulk materially by pressure when the circulation was controlled by pressure of the external iliac artery helping to give support in their minds to the diagnosis of abscess; but, on the other hand, there was a definite expansile pulsation to be felt throughout the whole tumour, which was far in excess of any impulse transmitted to the fluid contents of an abscess by an artery running through it. One naturally wondered, he said, what would have happened if the diagnosis of abscess had been acted upon and the swelling incised, as would have been done naturally under the circumstances, and what the operator should do if brought face to face with such an accident. He thought that digital pressure on the external iliac and firm pressure on the orifice made into the aneurysm would have served to control hemorrhage till some one could have exposed and ligatured the external iliac above the point of pressure, when the aneurysm itself could have been opened, its contents evacuated, and the profunda and superficial femoral ligatured.

There was a little transitory edema of the foot for a few days after the operation, otherwise the progress made has been most satisfactory. The patient was at once put on antisyphilitic treatment after the operation.

ROYAL FREE HOSPITAL.

OPERATION FOR COMPOUND DEPRESSED FRACTURE OF SKULL.—Mr. T. P. Lego operated on a boy, et. 5, who had been admitted after having been struck on the left side of the head by the shaft of a cart, the blow causing the child to strike the external iliac. In the region of the iliac there was an lacerated wound above Poupart's ligament. Operation was performed exposing the external iliac artery which was passed through the lacerated wound extending down to the bone, and exposing a linear fracture, two inches long, the lower fragment of bone being depressed about an eighth of an inch below the level of the upper piece of bone for the whole length of the fissure. The boy was quite conscious, the pupils were equal and re-acted to light; there was no muscular paralysis; the pulse was regular, and comparable; and there was no vomiting. The following operation was at once performed:—

The lacerated edges of the scalp wounds were pared, after the scalp had been shaved and thoroughly disinfected. A small trephine was then applied to the sound bone immediately behind the depression in the frontal bone. The piece of bone thus removed was packed away under the scalp in order to preserve it, with a view to its subsequent replacement. The depressed bone was completely removed by means of sequestrum and Hoffman's skull forceps. It was noticed that the dura mater did not pulsate until the depressed fragments were removed. The crown of bone removed by the trephine was replaced, and the wound in the scalp sewn up without a drain tube being
inserted. The posterior wound was now dealt with. As the margins of the fissure in the bone were infiltrated with dirt, they were removed by means of a Wood's saw applied parallel to and just outside the border. The edges of the skin wound were united by interrupted silk-worm gut sutures, a small drainage tube being put in its most dependent part, as it was impossible to get rid of all the infected tissues. Mr. Legg said that the case raised several points of interest. The first and most important was the avoidance of sepsis, which is the most important element of success in the treatment of compound fractures of the skull. The only means of making sure that this danger can be avoided is by removal of all infected pieces of bone and of the scalp. This cannot be efficiently accomplished by scrubbing with antiseptic lotions; the only certain method is by the use of the knife and bone forceps. The next point of interest, he remarked, was the depressed fracture in the frontal bone, which, though small, was evidently exerting considerable pressure on the dura mater, as was shown by the absence of pulsation until the fragments had been removed. The dura was not opened, as it did not bulge unnaturally into the gap left by the removal of bone, and there was no discoloration beneath it. Moreover, the absence of symptoms pointing to increased intra-dural pressure made it unnecessary to incise the dura. The third point, he said, was the question of replacement of the fragments removed. This, in most cases, is impossible when the fracture is compound; none of them were replaced in this instance, the fragment removed by the trephine was, however, replaced in order to diminish the size of the opening in the skull, as it was quite free from infection by dirt. It is, he pointed out, a well-known fact that such fragments, if replaced, will later become completely separated from the periosteum, and in this particular case it was impossible to stitch this structure over the replaced fragment of bone as well as over the adjoining portions. There are two chief methods, he said, of preserving the vitality of any fragments of bone removed during the operation. One, probably the better, was that adopted in this case, i.e., placing the fragment under the scalp where it is kept constantly surrounded by blood and at the body temperature. The age of the child was five, and if the fracture had not been compound the question of the advisability of operating would have had to be discussed; but when the depression is sharply defined and marked, in all cases he considered it better to operate. Owing to the fact that in such cases the internal table is almost always more damaged than the external there is the liability of the dura mater being injured and the probability of sequelae which may occur at a later date.

The after progress of the case was satisfactory in every way. Both wounds healed by first intention; the highest temperature was 100°, the day following; and the boy left the hospital on the seventeenth day after the operation.

Small-pox at Cambridge.

The epidemic shows no signs of abatement, fresh cases occurring daily. Police assistance has been necessary to preserve order in and around the vaccination stations, and some difficulty has been experienced in obtaining an adequate supply of vaccine.

An action was tried last week at the Liverpool Assizes in which Dr. Crawford claimed £835 for medical attendance on the late Mr. John Westmoreland, of the Imperial Hotel, Liverpool. It transpired that a bill of £10 against the estate of Mrs. Westmoreland had already been paid, and the jury returned a verdict in favour of the plaintiff for £599.

the medical press.

Aug. 5, 1903.

Statistics which, unless intended to serve as the basis for action, are mere waste of time. They cannot even be said to satisfy idle curiosity, for none is felt. Yet overcrowding exists in many a small, picturesque village in a more marked degree than even in our large cities, and is rendered more injurious by reason of the strikingly unhygienic conditions of rural dwellings in general. The smallness of the rooms, the tiny windows, and the contiguity of the cesspits to the well more than compensate for the ample supply of fresh air which is allowed to run to waste outside. The alimentation of the poorer classes in the country is deplorable. The choice of food is limited, it is often inferior in quality, and the people are woefully ignorant of the art of cooking, as town dwellers find to their cost when they quit their urban haunts for pastures new. We cannot afford to be indifferent to the consequences of this neglect on the part of rural sanitary authorities. The food supplies of towns are derived from the country, and the non-enforcement of regulations for the cleanly and sanitary conduct of dairy farms, for instance, is productive of much of the infantile mortality that swells the death returns of cities. The causes of this state of things, we are told, may be found in the absence of a strong central authority and the ignorance, apathy, and prejudice of the smaller authorities; and the remedy suggested is the creation of a minister of public health, who must, almost of necessity, be at the head of the Local Government Board. Without attaching an overweening importance to a ministerial creation, much might assuredly be done by insisting on the combination of the smaller public health authorities into areas sufficiently large to secure the services of an efficient medical officer, whose remuneration should suffice for him to give up the whole of his time to the duties of his office; in short, the service must be placed on such a basis as to tempt some of the best talent in the profession to enter it. Incidentally, adequate laboratory accommodation would have to be provided, and the tenure of office of medical officers of health must be rendered independent of the good-will of the persons on whose unsanitary toes he may tread.

The St. Bartholomew's Hospital Question.

Some months ago the proposal to rebuild and extend St. Bartholomew's Hospital on its present site was met by a storm of adverse criticism. The main objections urged were that, in view of the enormous cost of additional land and the conversion of a resident into a day population, it would be better for all concerned to build a new hospital in the suburbs, where land is cheap and population dense. The matter has been inquired into by a Mansion House Committee, who recommend that the hospital shall remain upon its ancient site. From the sentimental point of view, and also from the standpoint of philanthropists interested in this institution, the retention of its present position is undoubtedly desirable. The arguments on the other side, however, are so numerous and weighty that the mere assertion of the Mansion House Committee that objectors have based their criticisms upon "inaccurate information" can hardly be accepted as conclusive. Some more exact and convincing proof will be required before the public are likely to furnish further enormous sums for the extension of what is already the wealthiest endowed medical charity in the United Kingdom. The report of the Inquiry Committee asserts that the value of the present City site has been much exaggerated. It is, of course, easy to obtain a closely approximate estimate of the value per foot of the land involved. There need be no hesitation in assuming that the site value would reach a very high figure, although not likely to touch prices obtainable in some of the most central positions, such as Cornhill. The essential point, however, is the difference between the value of land lying between Smithfield and Newgate and land in the suburbs. A well-placed square yard of area in the City of London costs about as much as an acre of average land in the suburbs. Therefore, a cramped St. Bartholomew's in the City might become, without increased expenditure, a spacious pile of buildings, with a palatial scale of curtilage, in an outlying district. To say that the value of St. Bartholomew's has been exaggerated is simply to avoid the discussion of a main issue. The second proposition of the Committee is still less satisfactory. It asserts that there would be little, if any, ultimate profit in removing the hospital to another locality. As an ex cathedra statement of opinion, it will be noted that the views of the committee are stamped with an air of Spartan brevity and finality. We shall await with interest a full account of the arguments upon which so grave and emphatic a conclusion has been based. One incident in the course of the inquiry is significant. Captain Nott-Bower, the City Commissioner of Police, told the committee that the removal would be an inconvenience and a danger, because of the distance the police would have to take City accident cases. The implied suggestion that the removal of St. Bartholomew's Hospital to a suburb would preclude the provision of ample City accommodation for accidents and emergencies is absurd. Clearly, to leave behind wards for the reception of such cases, in case of removal, would be a first duty. It is not necessary, however, in order to provide accident and emergency accommodation, that many hundreds of sick and injured persons should be brought together from the suburbs and from the country to be nursed in a hospital in the heart of crowded London. The Mansion House Committee apparently accepted Captain Nott-Bower's evidence with full approval. Can they accept its corollary, as above stated, with equal complacency? On the whole, we think that the case for the retention and extension of St. Bartholomew's Hospital on its present site has not been satisfactorily made out. The decentralisation of the great medical charities of the Metropolis must sooner or later follow the decentralisation of the resident population. To
retain an institution for the purpose of housing a sick population in the centre of a huge city is indefensible on hygienic grounds. To retain and extend its premises on land of enormous value is, in our opinion, open to no less valid objection on economic grounds.

MEDICAL WITNESSES’ FEES.

The medical profession in England and Wales have, on the whole, good ground for congratulating themselves on the report which has been presented by the Departmental Committee appointed last year by the then Home Secretary to inquire into the allowances to prosecutors and witnesses in criminal prosecutions. For many years the gross injustice to which medical witnesses have been subjected in the matter of these allowances has been insisted upon, and proved to the full by constantly recurring cases. A typical example of the scale of fees which is at present in vogue was laid before the Committee. It showed that, in one case, a witness received the sum of ten shillings and sixpence for attendance at a police court for almost eight hours, and in another case a sum of two guineas for attendance at Assizes for eight hours on one day and nine and a quarter hours on the next day. In other words, the time of medical men is valued by the community at the sum of approximately two shillings per hour. The report of the Committee on the present scale is very definite and can hardly be evaded by the Home Office. “We think that the allowances hitherto paid under this head (professional evidence) have been inadequate, especially in the case of doctors summoned to places distant from their practice. It seems to us that the complaints made by the medical profession in respect of the present scale are justified by the very fact that its members are much more frequently called upon to assist criminal justice by evidence drawn from their professional experience than any other class of the community.” The report then makes the following recommendations:—

“We recommend, therefore, that the following be the maximum allowances in future:—For giving evidence in the town of residence, one guinea per case, but for more cases than one not to exceed two guineas for one day. For giving evidence away from the town or place of residence, one guinea per day in addition to the above.”

These recommendations, if not generous, can still be regarded as just, if one alteration is made and the word “maximum” is struck out. To give power to a local bench of magistrates, or even to a presiding judge, to order the payment of a smaller fee is manifestly unfair, and is well calculated to lead to abuses. The medical profession has clearly in its mind the recent utterances of a learned judge whose utterances, by the way, are not always governed by that judicial spirit which men look for from those in authority—with regard to the ability of a member of the medical profession who did not immediately diagnose antimonial poisoning in the case of a dying woman. With every respect for the eminent body of men who constitute his Majesty’s judges, we express the opinion that a judge who is not capable of forming a common sense view of the average capability of a medical man, and who expects to find the experience of a hospital physician and the knowledge of a professor of chemistry united in the person of a general practitioner, is also incapable of assessing at a true value the time of a medical man. If a guinea per case is a fair average fee, as the report of the Committee appears to indicate, it may be taken for granted that the cases in which it is earned easily will be more than counter-balanced by the cases in which it is earned with difficulty, by hard work and much loss of time. In the latter case, an increased fee cannot be granted, and why in the former case should the fee be reducible? Another recommendation in the report also calls for notice, as in its present form it creates a distinct injustice to medical witnesses, and at the same time an injustice which we believe is unintentional and contrary to the spirit which actuated the Committee. The report advises that if any witness is detained less than four hours from his home or place of business, he should only receive one-half the allowance which he would otherwise have received. If this recommendation is intended to apply to professional witnesses, it goes far to destroy the value of the other recommendations, but we do not believe that it is meant to so apply. As we have said, the recommendations do not err on the side of generosity, but they do go a considerable way to remove the gross injustice which at present exists. We trust that the Home Office may, without delay, give effect to them, and so supersede a scale of charges which dates back to 1858.

Notes on Current Topics.

The Jonathan Hutchinson Festival.

A correspondent writes:—“It was, as we all know, on Thursday, July 23rd, on his 75th birthday (really his 76th, by-the-bye, for we never count our first!), that we met to do honour to ‘our guest’ at the Balmoral Room of the Trocadero, under the chairmanship of the President of the Royal College of Surgeons of England. There were many of the best there, and, no doubt, many, like myself, who are only ‘as good as they can be.’ But we felt that the greatest general practitioner in the world was being honoured, and that attracted many of us—general practitioners! And what a speech it was, and how mounted in simplicity, I, for one, shall never forget! Here seemed an instance, as we listened, of an exception to the existence of the rule that the greatest work of the world is done by the talent of the world and not by the genius of the world. For if the ‘capacity for taking pains’ be genius, who shall deny to this man the genius he disclaims? But the fact is that genius has varieties, and is now and then Heaven-moulded and blended with a saving and sane alloy of talent also—as here! But I am concerned with the speech, and because it touched and ennobled the whole philosophy of earnest life. It was a sermon
of endeavour from one whose whole life is and has been a prayer. Sir Joseph Fryer had touched the true chord in his claim for ‘our guest’ of ‘fidelity to conscience.’ It was Huxley’s plea for truth ‘before all’ once more—the ‘truth’ that ‘never was indebted to a lie’ that Dr. Young spoke of in his ‘Night Thoughts’—And here were ‘Night Thoughts’ clothed in hues and language of eternal day. He spoke quite plainly, quite simply, quite without desire for effect. And therein was the effectiveness of every word ‘that fell like snowflakes from his lips.’ It was a wonderful little speech—I speak as a student of orators. I have heard the best, Bright, Gladstone, Castelbar, Cosen, Sexton, Sir James Paget, Falory, and I know ‘our guest’ was not ‘orating’—he was speaking what he felt in a way that made us all feel, and that is higher than all art. The art was in the avoidance of art. But every luminous sentence was a point of precision and help. He showed us that a great ideal cannot be classed with mere ambition, that a life-purpose has no pyrotechnics in it, and that the consciousness of work well done is the highest reward of the finest motives. And if that is not an exemplification of George Eliot’s phrase that ‘Fruit is Seed’ I really do not know what is.”

**Head Injuries and Suicide.**

The recent tragic death of a young clergyman as the result of a semi-conscious morbid impulse following upon a fall from a bicycle, illustrates the extreme importance of the effects of injury upon the brain, however slight, and also the dangers incurred by neglecting conditions of mild concussion. The facts of the case are briefly these. Early in the morning of the day of his death, the deceased gentleman, who was riding his bicycle in Hackney, and was seen by a spectator to fall therefrom, was able to return home and transact some business. Shortly afterward, he was found by a servant lying dead in his bedroom with a bullet wound behind and above the right ear, a revolver being found beside him. The medical evidence at the inquest was to the effect that the act was automatic, and that he was in a dazed state consequent upon the fall from his bicycle. Instances similar to this are well known, in which the sight of any object suggests to the beholder its immediate use. Conditions of automatism are not uncommon as a result of traumatism, and in those states of slight concussion of the brain, in which consciousness is not altogether lost, imperative ideas are often seen as the outcome of the mental disturbance produced, the individual being absolutely irresponsible for his actions. The importance of injury to the head as a factor in the production of insanity is well recognised, and epilepsy may frequently be traced to traumatism, either in the patient himself or sometimes in the parents. It is one of the golden rules of medical practice never to pass over lightly any injury to the head or spine, however trivial such may apparently be. The after consequences may be delayed for some time, or they may manifest their presence immedi-

The **Evolution of Abdominal Surgery.**

The introductory address in surgery delivered by Mr. Mayo Robson last week at Swansea is a brilliant exposition of the steps by which surgical practice has advanced to its present high position, virtually within the lifetime of the present generation. In many of these advances the author, it cannot be denied, has taken a prominent part, although, with characteristic modesty, he has devoted his attention rather to the achievements of others than to his own. The great lesson which we deduce from the address is that progress in surgery is attainable only by the closest attention to details. Many a major operation now in daily use only gained scientific recognition after years had been spent in elaborating the, at first sight, insignificant details thereof. But—and this is a point to which the lecturer did not refer—success in surgery is dependent on early diagnosis, and towards this end physicians and pathologists have laboured in common with their surgical brethren. In no department of medicine has progress been more marked and undeniable than in diagnosis, thanks, no doubt, in part to the fact that surgeons have a simple way of their own of throwing light on obscure points, viz., by making an opening. That simple procedure, however, is not applicable to a large proportion of cases of suspected cancer, appendicitis, and the like, in which the success of a surgeon is greatly dependent on the perspicacity of the physician. Although abdominal surgery in its widest sense has sprung into being and developed within the last third of a century, something more than merely crossing the threshold has been accomplished, though much remains to be done. There is promise, however, that before another thirty years have passed the progress of therapeutics will have done something to restore the balance in its favour.

**Human Barometers.**

Just as “there is in souls a sympathy with sounds” so is there some subtle and mysterious connection between the body and its functions and the state of the atmosphere. In many people an increased vivacity is experienced before the approach of rain, which symptom is in common with those displayed by the lower animals, and similarly in wet weather a sense of drowsiness or incapacity for exertion is sometimes felt. Many of the bodily sensations are capable of a physical explanation, such as the well-known aching of corns before rain, which is due to the heightened congestion of the parts owing to the decrease in the barometric pressure. There are, it is true, some individuals of equable temperament who never appear to be influenced in the slightest degree by atmospheric conditions, and who can work with equal facility in extremes of cold and heat, wet or dry. It may be that their power of adaptation to their physical environment is unusually strong, but they are the envy of
more susceptible persons who cannot so adapt themselves. It was Dr. Weir Mitchell who called attention to the fact that neurotic individuals are most influenced by the state of the weather. Certain forms of headache are very prone in them to coincide with electric conditions of the atmosphere. They are the people who have "presentiments of thunder in the air," and nearly always their predictions are verified. In some cases the incidence-curves of headache coincide almost exactly with the curves of the summer electric storms, when represented graphically. Mental depression in some, and irritability in others, is closely dependent upon the absence of sunshine, and in weak nervous states a period of dull weather has been known to retard convalescence to an appreciable extent. With the exception of a small minority, everyone is influenced more or less by atmospheric changes, though it is possible, and indeed desirable, not to allow oneself to be so affected.

A New Contrast Stain.

Though the average microscopist is coming more and more to rely on a few practical stains for routine use, yet he is always interested in experimenting with new modifications. For instance, all who are interested in the clinical examination of blood have now learned that there is no stain as convenient as Leishman’s preparation of casesin and methylene blue, and he gladly substituted it for that of fast green. Similarly, we are now offered a contrast stain for cells and bacteria which, we are told, gives excellent results. One per cent. solutions of pyroxylin and of methyl green are made separately, and mixed in the proportion of four parts of the former to one of the latter. The films (e.g., of pus) are prepared in the usual way, and a few drops of the colour placed thereon. They are gently heated for a few seconds, and then washed in water. On examination the nuclei of the cells are seen to be green, while bacteria show out clearly a brilliant red. As by most other methods of staining bacteria and nuclei take the same colour, the advantages are obvious.

Progress in Cancer Research.

The first annual report of the Cancer Research Fund, read before the general committee of the Association at a meeting held on July 30th, showed that a considerable amount of work has already been accomplished since its formation in the shape of necessary preliminary organisation. It is very gratifying to note the very wide basis and scope of the inquiries instituted, and also the large amount of assistance both given and promised by the various Government Departments, Home and Colonial, the medical Corporations, as well as numerous individual members of the medical and veterinary professions. The investigations in progress fall mainly into three groups—experimental research, therapeutic work, and general cancer statistics. It is hoped that special attention will be paid to the nature and appearances of cancer as it is seen in the animal kingdom, and to such important questions as the methods to be adopted for the more early diagnosis of malignant disease, and to the transmission or heredity of cancer in general. The report having been accepted, Mr. Balfour, who occupied the chair as one of the Vice-Presidents of the Association, delivered a most able and stirring address on the work and objects of the inquiry, in the very breadth of which, it was stated, there is much encouragement to be derived. The necessity for co-operation in research of this kind is very urgent, as even in science union always proves to be strength. The value of the comparative study of cancer, undertaken in a thoroughly systematic manner, cannot be over-estimated, for, as has been the case with tuberculosis, much of our knowledge, and indeed all that relates to sero-therapy, has been gained by the observation of the disease as it appears in animals. We look into the future with hope, and we trust that the noble work of this Research will not be hindered by the lack of the necessary funds.

Motor Car Legislation.

The measure now in the process of legislation having for object the regulation of motor car traffic threatens to press hard on the provincial practitioner who has adopted this rapid and, on the whole, economical mode of conveyance. Should he be convicted on the uncorroborated evidence of a police constable of driving at an unduly rapid pace he may be heavily fined or even sent to prison, while his licence may be revoked. What would be the predicament of the medical owner of a motor car deprived of his licence? He cannot dig, and to beg he would be ashamed, yet if he be deprived of the means of visiting his patients at a distance he would have to adopt one of the alternatives. And, when hurrying to an urgent case, he would be but too likely to trangress the law. It amounts to this, that the provincial practitioner would have to take care to keep on good terms with the police, even to the extent of attending them for nothing, rather than run the risk of incurring their displeasure. Such a position would be intolerable, and we would urge on medical members of Parliament to endeavour to obtain some latitude for medical men when engaged in bonâ fide professional work. We have seen it stated, though we are unable to say on what authority, that under an antiquated law medical men are accorded certain privileges in the matter of speed and short cuts, and perhaps our readers can assist us in refurbishing these antique exemptions for present use.

Galactorrhoea in the Virgin.

Cases of this class are sufficiently rare to make the one reported by our French correspondent sufficiently interesting to place on record. The patient was under Professor Gauthier, of Paris. She was a spinster, twenty-five years of age, of a nervous temperament, though otherwise in good health. She menstruated at fifteen years of age and for the following five years her changes were normal in
frequency and amount; after this the changes ceased for three months, during which time her breasts became swollen. Five years afterwards she again suffered from amenorrhoea; the menses appeared irregularly and finally ceased altogether. With this cessation was established a copious secretion of milk in both breasts, and it flowed so freely that the patient found it necessary to swathe her breasts with napkins, which had to be frequently renewed. By applying pressure around the nipple she could produce a copious flow of normal human milk. At the end of five days the flow diminished, and finally ceased. But on the occurrence of each menstrual period the galactorrhoea returned for five or more days, and so continued until the sixth month. She was now treated for the nervous condition from which she was suffering, and at her sixth menstrual period the flow of milk was decidedly less and she had a slight menstrual discharge. From this she continued to get better and in a few months was quite well. The whole period during which she suffered galactorrhoea was twelve months.

Visceral Lesions in Acute Insanity.

The bodily conditions which determine or accompany the various forms of mental aberration is a subject which never fails to excite the interest of the physician and the alienist alike. We are yet in ignorance of the reason why the sensations proceeding from diseased or deranged organs should in certain cases be more vividly construsted, but there is reason to believe that it is along physical lines that our knowledge of the pathology of insanity will ultimately be advanced. Dr. G. R. Wilson and Dr. Chalmers Watson record in the the Journal of Mental Science two cases of acute mania, both in females, in which visceral changes of a more or less pronounced type were discovered post mortem. The morbid appearances consisted in a chronic form of bronchitis, a chronic congestion of the gastro-intestinal tract, and one case presented a small-celled infiltration of the mucous and submucous coats of the bladder, evidently of long standing. In both cases the bone-marrow was observed to be abnormally red and to contain scattered areas of gelatinous-looking material. In neither instance did the clinical symptoms lead to any suspicion that the visceral lesions were of so grave a nature. The character of the lesions were, broadly speaking, atrophic and hypertrophic, the latter being considered as an early stage of the former. The observers do not, of course, pretend to form any conclusions from these two cases as to the cause of acute insanity, but they only desire to point out the value of a more careful clinical study of individual cases, especially from the physical standpoint. The science of neuro-pathology has made many strides of late years, owing to improvements in the methods of research, but in view of the possibility that mal-nutrition of the brain may result from lesions in various parts of the viscera the study of ordinary morbid pathology must still continue to be pursued as keenly as ever.

Leucocytosis in Variola.

The occurrence of a leucocytosis in various inflammatory disorders is now recognised as an established fact, and in many cases its presence or absence forms a not unimportant factor in arriving at a correct diagnosis. The clinical value of the blood-count apart from blood-diseases is somewhat tardily receiving the appreciation that its merits demand. Leucocytosis in small-pox has been known and described by Brouardel, Hayem, Pick, Emile Weil, and MM. Courmont and Montagard. Dr. Alexander Furguson, of Glasgow, has further elaborated the subject and has embodied the results of his researches in a recent paper in the Journal of Pathology and Bacteriology. The special feature of the leucocytosis is that it is mononuclear in character. It is not generally present before the appearance of the rash, and usually attains its maximum by the eighth or ninth day. The lymphocytes and smaller hyaline cells are always increased in number in the more severe cases, in which eosinophile cells and nucleated red corpuscles are also seen. As in other forms of suppuration, the leucocytosis is most marked in the stage of pusulation, after the subsidence of which it gradually begins to decrease, persisting, however, in a slight degree for some time after the acuter symptoms have passed away. The appearance of abnormal cells, such as derivatives of the bone-marrow, are regarded as of graver prognostic significance, though in some instances their occurrence may be only accidental. Taken in conjunction with other physical signs the results of blood-examination in variola may be of assistance in forming an opinion upon the severity of the case.

Bacteria in Swimming-Baths.

The popularity of the public swimming-bath during the hot summer season is largely due to the physical gratification experienced by the free and unrestricted movements of the limbs combined with the exhilaration produced by a more or less prolonged contact with the cold water. The average Britisher who takes his daily morning "tub" does so partly from a sense of duty, and in his early ablutions he has no time to waste. The purity of the water in municipal baths is a matter of the greatest importance when the large number of bathers who frequent them is taken into account. In a paper by Drs. Glynn and Matthews, read before the Congress of the Royal Institute of Public Health at Liverpool, it is distinctly shown, as might be expected, that the cleanliness of the water varies in direct proportion to the "class" of the bath, that in the first-class containing the least number of bacteria, and also that the salt-water baths contain less than the fresh-water ones. The question as to whether the risk of contracting disease in this manner are great or not can hardly be settled by one series of observations, but the injurious effects, if any, must depend upon the pathogenic character of the bacteria present in the water at a given time. The organic substances in the dirt and epithelial

Corsets or No Corsets.

We have been accustomed for so long to credit corsets with a lengthy train of all the ills that female flesh is heir to that it is quite refreshing—right or wrong—to come across an article in praise of the corset. It seems that we have been quite wrong in laying to the door of this much-abused article of attire ailments of such varied nature as floating kidney and constipation, anaemia and dyspepsia, dyspnœa and dysmenorrhœa, of whose causation tight-lacing afforded such a convenient explanation. We know one worthy gynaecologist who is accustomed to explain the serious deviations from health which come under his notice as due to excessive "tea-drinking," but for how many was the tight corset a ready scapegoat! However, Dr. Gallant, of New York, (a) has put an end to all this, and has shown that the veritable culprit is not the corset, but the waist-band. Let us hear his indictment:

"As the spinal column lengthens, it should carry upward all the viscera attached thereto, but, owing to the weight of clothing and compression at the waist-line this process cannot take place, stretching of the ligaments occurs, the viscera are thereby dislodged and hang at a level much below the normal. . . As a logical sequence, pouching of the stomach results in food retention, fermentation, gastro-intestinal indigestion, intestinal inactivity, and auto-infection from resorption of excrementitious matter too long delayed within the alimentary canal, manifested by coated tongue, hepatic torpor, dusky skin, dark, scanty urine, dysuria, frequent headache, general malaise, anaemia, menstrual disturbance, defective vision, &c."

(One is grateful for the " &c.," for the list might have been interminable.) Luckily, the condition is not altogether as hopeless as we might expect, for Dr. Gallant knows not only the disease (as we have seen), but the cure. Truly is the corset revenged.

The Prokhorow Treatment of Syphilis.

In view of the extreme importance of a systematic mercurial treatment in all cases of syphilis, it has long since been recognised to be unwise to leave its administration in the hands of the patient. Another reason for the treatment being carried out by the medical adviser is that it is possible to adopt the method of administering the mercurial salt by intra-muscular injections, a method which has much to recommend it by reason of the satisfactory nature of the therapeutic results thus obtained. The pain associated with the method of injection will not be objected to by the majority of patients, seeing that such injections do not require to be made more than once, or at most, twice a month. In this connection we have read with interest a monograph by Dr. F. L. Nario, of Buenos Ayres, on Prokhorow's plan of treating syphilis by means of intra-muscular injections of a solution of the biniode of mercury containing thirty centigrammes of the biniode of mercury and sixty centigrammes of iodide of potassium in fifty grammes of distilled water. This solution contains six milligrammes of the salt in each cubic centimetre. The dose is half a cubic centimetre per kilogramme of body weight in the adult, and half that quantity for children, and the treatment comprises a generous dietary pushed to hyper-alimentation. In children Dr. Nario claims to have obtained specially good results, but it is necessary to remark that as a rule a single injection suffices to determine the retrogression of the syphilitic manifestations, in which event no further injection is made for thirty days. If necessary, however, it may be repeated in a fortnight. When five injections have been made a long period of repose is desirable. In adults he injects once a month for the space of a year. A complete course of treatment by twelve injections would be a desideratum, and this method certainly promises to revolutionise the treatment of syphilis.

Climate and Menstruation.

It has long been regarded as a commonplace that menstruation appears earlier in warm than in cold countries. High temperature was supposed to have a direct positive effect in the early maturation of the sexual organs, and the comparatively late puberty of these islands was assigned to their cold climate. It would seem, however, from the statistics published recently by Engelmann at the International Gynaecological Congress at Rome, that this generality is somewhat too wide for the facts, and will have to undergo considerable modification, if, indeed, it is found to disappear entirely. The variation in the age of puberty seems to depend much more on racial and dietetic conditions than on mere difference in latitude. In Europe alone is it true that the warmer the country the earlier menstruation begins. Jewesses, in whatever clime they may live, are known to come to maturity early, while Somali girls, living under the Equator, are as slow of development as Lapps, living in Arctic regions. On the other hand, Indians of Northern Canada develop very early (the average age at first menstruation being 12½), and the Esquimaux are also early. Strange to say, the highest average is in Cochín, China, where the age of puberty is placed at 16½ years.

Proposals for improving the pay and general conditions of the Indian Medical Service have now been formulated by the Government of India, and will shortly be taken into consideration by the Secretary of State for India in Council. It is hoped that the revised terms will be published in September.

(a) "Canadian Journal of Medicine and Surgery, July, 1903."
The success of the open-air treatment, according to Dr. Ransome, lies undoubted in its blood-making power, which, he states, is not the usual explanation given. It is generally thought that it is simply owing to hygienic measures that the powers of the patient are so invigorated as to enable him to fight successfully against the attacks of the bacillus. The whole question of "polycythemia" in the cure and prevention of consumption is one which is well worthy of careful attention.

Dr. H. E. W. Hoffmeister has been appointed Surgeon in Ordinary to the Princess, Henry of Battenberg.

The Barker Anatomical prize, open to all medical students in the United Kingdom, has been this year awarded to Mr. Alfred Norman Crawford, a student of the Royal College of Surgeons, Dublin.

Dr. William Collier, Senior Physician of the Radcliffe Infirmary, has been nominated President of the British Medical Association for the meeting which is arranged to take place at Oxford in 1904.

### BRITISH MEDICAL ASSOCIATION

#### 71ST ANNUAL MEETING, SWANSEA, JULY 28TH TO AUGUST 1ST, 1903

The South Wales meeting of the British Medical Association, although unmarked by any epoch-making pronouncement on matters medical, has nevertheless proved eminently successful, and the "doctors' picnic," as cynics are wont to describe the annual gathering, has furnished much material for pleasant memories. It is estimated that upwards of 700 members attended. Swansea is not readily accessible, and certainly lacks in beauty and suffers from many limitations, and, moreover, the weather was hardly of the best for the full enjoyment of the many delightful excursions and out-door receptions provided by local hospitality. The surrounding country is rich in natural beauty, and full of historical and archaeological interest; and the advantages offered by South Wales as a desirable health and holiday resort were well demonstrated to the visitors who gathered from all parts of the country.

A "souvenir" was presented to each member, in which the attractions of Swansea Bay were excellently illustrated and suitably described. A convenient "Excursion Guide" afforded particulars of the many outings arranged for members and friends. The "Daily Journal" was published each morning in its customary form. The local press devoted much space to the records of the meeting, and much hospitality was extended to all the visitors to the Principality. The President, Dr. T. D. Griffiths, and all his colleagues may well be congratulated on a most successful gathering.

### THE ANNUAL CHURCH SERVICE

There has always been a close association between the pulpit and the practitioner, and on the present occasion very appropriately the Right Rev. the Lord Bishop of St. David's, on Tuesday morning, July 28th, preached the annual sermon from the text "Christ also suffered."

### REPRESENTATIVE MEETINGS

The reconstitution of the Association has been accomplished with the minimum of discomfort, and it may be hoped will have gone far to secure the maximum of efficiency. Certainly the meetings of the "representatives," ably presided over by Sir Victor Horsley, have furnished strong evidence that a change for the better has been accomplished. Much

---

**Polycythemia and Phthisis.**

It has long been recognised that individuals with certain morbid tendencies appear in some way to be immune to tuberculous infection. The antagonism between gout or morbus cordis and phthisis is a favourite topic among clinical teachers. Those bodily conditions in which plethora of the vessels is a marked feature seem to render the subject proof against the invasion of the tubercle bacillus to a great extent. The character of the blood itself, both in the early stages of pulmonary consumption and also at the expiration of a period of sanatorium treatment should afford some trustworthy information as to the effects of pure air upon the progress of the disease. Dr. Arthur Ransome, in a valuable article upon the subject, finds that a considerable "erythrocytosis" is one result of sanatorium treatment, and it is interesting to note in connection with this that at higher altitudes the number of red corpuscles is greater than that observed at lower levels, which statement has been confirmed by actual experiments upon the same individual at different elevations. The bactericidal power of the blood is increased by its "hyper-aeration," though it would appear that even a venous plethora affords some protection against the infection. Nevertheless, it is manifestly the abundance of rich arterial blood which is needed for the cure of the disease.

---

*(a) *The Medical Chronicle, April, 1903*
time was spent on the consideration of the draft Standing Orders and the report of the Council. Although the Council may be expected to fulfi its duties as a medical ‘House of Lords’ in true conserva
tive fashion, there is strong reason to believe that the “representatives” forming the Commons’ will and intent body will move wisely progressive with a statesmanlike precision, and direct, by a scientific knowledge of the needs of the profession.

The reports of the proceedings of the Council and the representative meetings were duly published in the “Daily Journal.” It is to be regretted that the initiation of the new dispensation has awakened but little interest among the majority of the visitors, and it is to be hoped means will be found for quickening that interest existing among the members of the British Medical Association.

The General Meetings.

On Tuesday afternoon, July 28th, the retiring President, Mr. Walter Whitehead, of Manchester, introduced the new President, Dr. T. D. Griffiths, whose portrait we were able to present in our last week’s issue. The same evening the President delivered his address in the Albert Hall, before a large audience of ladies and gentlemen. He dealt with the evolution of the anatomical surgery, and its influence on the progress and advancement of bacteriology and therapeutics, and furnished an interesting retrospect and forecast concerning many points of paramount importance to the medical profession. His references to the conduct of nursing homes and sanatoriums, and to the improvement and extension of procedure in the practical application of scientific knowledge to public health aroused much interest, and has furnished material for careful consideration.

The reception of foreign visitors and representatives of colonial branches, who formed but a small gathering, preceded the Presidential Address. A particularly interesting case was the presentation of the Sylvanus Price to Dr. F. W. Mott, F.R.S., in recognition of his researches concerning asylum dysentery and the influence of syphilis in the etiology of diseases of the nervous system.

The Special Addresses.

The address in Medicine was most appropriately delivered by Dr. Frederick Thomas Roberts, Senior Physician to University College Hospital, who spoke with characteristic felicity on infective and infectious diseases, particularly on the practical importance of etiological factors, and indicating the value of scientific precision in the study of clinical phenomena and the service of rationally conducted prophylactic measures.

Professor A. W. Mayo Robson was the orator in Surgery, and wisely selected a subject which he has made particularly his own—Abdominal Surgery. His address was a luminous presentation of personal reminiscences extending over a third of a century and based on a record of two thousand operations.

The Work of the Sections.

The real work of the meeting is supposed to find expression in the various sections, which at the present meeting numbered eleven. Unfortunately, the sections had to hold their gatherings in two separate buildings, although generally the rooms provided were convenient and more than sufficient as regards size for the meagre audiences. The material presented in most instances cannot be considered notable, and most of the discussions were lacking in distinction. It is much to be hoped that under the new system there will be found to revivify the scientific work of the sections, and secure a satisfactory presentation of the best results of recent research. Unless a high standard of efficiency in the scientific work of the sections is maintained, the annual meeting of the Association will speedily cease to attract serious workers, and will lose in dignity and powers of service to the profession and humanity.

We are of opinion that the Council should devote particular attention to the conduct of sectional arrangements. It would be well if in all cases an adequate synopsis of each introduction to a discussion and a short summary of every paper were made available at least a week before the commencement of the meeting. Unless some such departure from the haphazard procedure which seems at present to rule in certain sections, it will be impossible to secure a representative expression of the best professional opinion on a subject, or obtain anything like satisfactory conclusions based on collective investigation. We are glad to see that in some of the sections an attempt was made to meet the needs of the scientifically minded by presenting in the “Daily Journal” a synopsis of the papers introducing certain very important discussions.

The Medical Section.

The work of this section was particularly disappointing. The subjects selected for discussion were not peculiarly attractive and aroused but limited interest.

Dr. P. M. Chapman introduced the subject of the medical treatment of inflammations in the caecal region; Dr. N. D. Rolleston opened the discussion on the treatment of peptic ulcer; and Dr. Robert J. M. Buchanan summarised recent work on susceptibility and infection.

Among the communications presented in this section were papers by Dr. Wilfred J. Girrour on the treatment by operation of Erb’s palsy, traumatic paralysis of the upper extremity, and infantile paralysis by cross-union of the nerve trunks; Dr. George Parker on bronzed diabetes; Dr. McVail on the treatment of uraemia by spinal punctures; Dr. L. Kelvynack and Mr. M. Sydney Williams on the relative value of rectal and oral temperatures in the study of cases of pulmonary tuberculosis.

The sub-section devoted to electro-therapeutics attracted considerable attention, and the discussion on the results of treatment of malignant disease by electrical methods, opened by Dr. Lewis Jones, was of much interest, although the general trend of opinion seemed clearly to indicate that the “role” of electricity in permanently arresting malignant growth was but of very limited service.

Dr. Chisholm Williams opened a discussion on the application of electrical methods in the treatment of tuberculosis, and furnished evidence which went to show that considerable benefit might accrue from the rational application of this agent in suitably selected cases.

Surgery Section.

The most important feature of this department was the excellent discussion on methods of intra-abdominal abortion, ably introduced by Mr. G. R. Oliver and Mr. E. Stainton Bishop. Special interest was aroused by the admirable diagrams and valuable series of preparations presented by Mr. Bishop. The discussion was essentially practical and of special service, in that it was mainly devoted to the exposition of technical difficulties and the procedures by which they might be overcome.

A discussion on the treatment of advanced tuberculous disease of the knee joint attracted considerable attention; and a number of papers of more than average interest were read.

Section of Obstetrics and Gynaecology.

The chief discussion in this section was directed to the management of pregnancy complicated with uterine fibroids, opened by Dr. Amand Routh, who dealt with the effect of pregnancy upon the fibroids and then proceeded to discuss the effects of fibroids upon pregnancy. He advocated an expectant treatment unless urgent symptoms existed, and indicated the best procedures to be followed before and after fetal viability, and during the puerperium.

An interesting discussion also took place on the diagnosis and treatment of tuberculosis of the uterus and adnexa.

Many papers of much interest were also presented.

Section of State Medicine.

This section proved the gathering ground for many medical officers of health and others specially interested in public hygiene and preventive medicine.
An opportune discussion took place on the Vaccination Acts and small-pox prevention, opened by Dr. J. C. McVail, of Glasgow.

A paper which aroused considerable local interest was presented by Dr. Newsholme and Professor Hunter on sea-shore pollution and its effects on oysters and other shell-fish and the pisciculture of estuaries.

Many other papers of considerable interest to sanitarians were read.

PSYCHOLOGY SECTION.

One of the best sections was presided over by Dr. Robert Jones, of Claybury Asylum. Here Dr. W. Ford Robertson opened an excellent discussion on the pathology of general paralysis, and strongly supported the view that it depended on a chronic toxic infection from the respiratory and alimentary tracts, permitted by general and local impairment of the natural defences against bacteria and due to the excessive development of various bacterial forms, especially the abundant growth of diphtheroid bacillus. The widely-accepted view that general paralysis is dependent upon a syphilitic toxæmia was strongly controverted. Dr. Robertson gave a lantern demonstration illustrating some pathological anatomical features in the case of general paralysis of the insane, which afforded support to his views; together with the results already obtained in the course of an experimental inquiry.

A paper on alcohol in relation to mental diseases, opened by Dr. Theo R. Hyslop, attracted much attention and elicited important communications from Archdall Reid, Dr. Mercier, Dr. T. N. Kelync, Dr. Yellowlees, Dr. Andrieueu, Dr. Eldridge-Green and others.

Dr. Yellowlees opened a very practical discussion on the care and treatment of incipient insanity; other papers of considerable value were also read.

PHYSIOLOGY SECTION.

The chief features of note connected with this section were the valuable opening address of the President, Professor W. J. Hamilton, on the inoculability of human tuberculosis upon bovines; Professor Thomas Oliver's introduction to a discussion on the pathology of miners' diseases; and Dr. Rolleston's summary of the pathology of splenic anæmia.

The more important preparations exhibited in the small but select Pathological Museum we hope to describe in our next issue.

OPHTHALMOLGY SECTION.

The attendance at this section was, as might be expected, small; but serviceable discussion took place on the operative treatment of conical cornea, opened by Dr. Staines-Morton; onular changes in relation to renal disease, introduced by Mr. Edward Nettleship; and the treatment of convergent squint, dealt with by Mr. Hartridge.

DISEASES OF CHILDREN.

Three discussions of much interest were held by this section. Dr. D. B. Lees dealt with the pathology and treatment of chorea; Mr. Burghard discussed the management of congenital dislocation of the hip; and Dr. Nathan Raw, in his address on tuberculosis in children, and its relation to bovine tuberculosis, held that the human may be affected by two varieties of tubercle, one conveyed by infection from one person to another, the other bovine tuberculosis, conveyed by milk from tuberculous cattle.

LARYNGOLOGY AND OTOLGY.

Good work was accomplished in this section, the chief interest centring about the discussions on operative treatment for malignant disease of the larynx, introduced by Sir Felix Semon and Dr. E. J. Moore, of Bordeaux; the technique of operations on the temporal bone in suppurative middle-ear disease, by Dr. P. McBride, of Edinburgh; and Dr. Arthur Hartmann, of Berlin; and the upper respiratory tract as a source of systematic infection presented by Dr. de Haviland Hall and Dr. Jobson Horne.

NAVY, ARMY AND AMBULANCE.

This section bot unnaturally received somewhat scanty attention although valuable discussions took place on such important matters as the personnel, equipment and training of medical units attached to volunteer infantry brigades, the poverty of attraction for men to become regimental bearers, the training of volunteer bearers, and the position of regimental medical officers.

TROPICAL DISEASES.

Sir Patrick Manson opened a valuable discussion on trypanosomiasis, and after indicating the methods for examination of blood for tropical micro-organisms and the clinical features of trypanosomiasis, showed the possible relationship to other diseases, particularly sleeping-sickness. Sir Patrick showed that the prognosis of trypanosomiasis is not necessarily bad while that of sleeping-sickness is always so.

Mr. Jonathan Hutchinson again presented his new well-known hypothesis in favour of fish as a means of spreading leprosy.

Professor W. J. Simpson opened a discussion on the very practical subject of the disposal of excreta in the tropics.

We shall hope to present abstracts of certain of the more important papers in subsequent issues.

ENTERTAINMENTS AND EXCURSIONS.

Numerous receptions, garden parties, and excursions proved exceedingly popular, and afforded many opportunities for congenial intercourse, pleasant private discussion, interchange of views and the renewal of old friendships.

Among the most popular was a visit to Craig-y-Nos Castle, the picturesque residence of Baron and Baroness Cederstrom (Madame Patti).

Receptions were also held by the President and local executive committee and the Mayor of Swansea.

On Saturday, August 1st, excursions took place to Tenby, Llanwrtyd, Llandiniod and Caerphilly.

On Tuesday, July 28th, the President, Dr. T. D. Griffiths, gave a luncheon, and among the guests were the Mayor of Swansea, the Bishop of St. David's, the Vicar of Swansea and members of the Council and officers of the Association.

The annual dinner was held on Thursday evening, July 30th.

THE ANNUAL EXHIBITION.

The "trade" exhibit, in spite of the discouragement and disdain of the few, still remains a popular feature with the many. For the busy practitioner it affords a ready, convenient, and pleasurable means of introduction to new preparations, and goes far to make, what may be, sometimes to renew, an acquaintance with tried and trusted firms. At the present day the wisest practitioners are those who recognise the necessity for a scientific co-operation with the pharmacist and instrument maker, and all those who appreciate the development of rational medicine and the application of technical knowledge to the details of the healing art. It is therefore very desirable that great judgement and much discrimination should be conspicuous in the conduct of the affairs pertaining to the Annual Exhibition of Fools and Drugs, Medical and Surgical Instruments, and Sanitary and Ambulance Appliances.

The present year's "show" has been a fairly representative one, although many well-known firms were conspicuous by their absence. Unfortunately, the accommodation in the Swansea Free Library afforded altogether inadequate opportunities for a satisfactory display; and exhibitors on the first and second floors, in the School of Art and Art Gallery of Engravings, in spite of their artistic surroundings, suffered from their elevation.

The exhibition, however, was well patronised, and the customary means for the giving and getting of "samples" duly provided. As far as we could ascertain, no very startling novelties were forthcoming, but the presentation of many old favourites testified to the favour of numerous popular preparations, and doubtless assisted in the widening of the connections of many old-established firms.

The number of exhibitors was somewhat less than
usual, but we counted eighty-four separate "shows," and the catalogue of the exhibition, in its customary panel-like and most convenient book form, ran to 152 pages.

A number of well-known chemical and pharmaceutical firms furnished attractive exhibits. Messrs. Parke, Davis, and Company had an interesting stall on which were displayed their well-known standardised fluid extracts, serums and toxins, chocolate-coated tablets, medicinal elixirs and syrups, effervescent tablets and granules, euthymol preparations, digestive products, and such well-known agents as acetozene, adrenalin, chloroetone, aseptic logot, liquor sedans, together with a goodly show of medicine cases and chests.

The Denver Chemical Manufacturing Company showed their new antiphlogistine, a non-irritating antiseptic absorbent for the local treatment of inflammatory conditions.

The well-known Bayer Company displayed numerous pharmaceutical products from their famous manufactory at Elberfeld, including aquarin, a preparation of thecine; aristochin, the carbinic ester of quinine; aspirin, the now much-used substitute for salicylic acid and its salts; aristol, helmitol, hedonal, somatose tannigen, thecin, and also many very convenient photographic products.

Messrs. Oppenheimer, Son, and Company showed their popular palatinoid preparations, concentrated liquors, and other special products.

Messrs. Hewlett and Co. displayed their well-known preparations to advantage. Special attention should be drawn to their very convenient hot-water bath and discs for the application of Unna's pastes.

Messrs. Arthur and Company showed their special cosmetic and other elegant preparations.

Messrs. Wyleys, of Coventry, presented an elaborate and attractively arranged stall on which their well-known labattum preparations were exhibited.

The Charles U. Phillips Chemical Company exhibited an elegant "milk of magnesia.

Messrs. J. T. Davis and Company, of Swansea, displayed a good selection of medical and surgical appliances, but the number of local firms exhibiting was but small.

Messrs. S. Kutnow and Company were to the front with "Carabon Powder," and their widely-known "Anti-Asthmatic Powder."

Messrs. Ferris and Company, of Bristol, made a good display of their convenient specialties.

Messrs. Burgess, Burbidges, and Company showed the pharmaceutical products of Von Heyden, including acine, cresotal, xerofem, and salocele.

Messrs. Scott and Bowne still sought to declare the particular advantages of "Scott's Emulsion."

We regretted to see that too much space had been allotted to certain brewers and wine merchants, and venture to think that it will be well in the future to carefully limit the display of "the trade" in an exhibition devoted to scientific medicine.

The exhibitors of prepared foods and food products were present in considerable numbers. Bovril was, of course, to the fore, and Virol and other attractive preparations were duly sampled.

The Chelten Foodstuffs were present in endless variety and attractiveness. The British Somatica Company also showed samples of their various preparations.

The Aylesbury Dairy Company had a goodly show of their well-known and justly popular milk preparations. Maitova was also represented.

Messrs. Cadbury, of the garden town of Bournville, displayed chocolate in all its fascinating varieties.

The needs of the diabetic were well catered for by such firms as Van Abbott and Sons, Callard and Company, and the Manhu Food Company.

Such old favourites as Mellin, Nestle, Liebig, and Brand made conspicuous and attractive stalls.

Messrs. Broomfield and Company showed their pure and refined vegetable fat, "Albene."

The Shredded Wheat Company made an attractive display of their dainty and very useful preparations.

Billon's Ovo Lecithin was also exhibited. The usefulness of Robinson's Barley was also duly proclaimed, although this article has been before the public for eighty years.

Coesenza and Company had a good display of their famous Maggi's preparations.

The Marmite Food Extract Company exhibited their new vegetable extract; and "Vegox," a very palatable food essence, met with favour.

Various mineral waters occupied a prominent place.

The advantages of those of Harrogate, Llanwrtyd Spa, and Leamington were duly declared. The Apollinaris Company and the dispensers of "Friedrichshalt" made good shows. Camomile tea was well represented. A new natural mineral water, "Arabella," at least furnished an attractive name.

The well-known providers of lime-juice were as usual much to the front.

The surgical instrument makers were present in small numbers, but such firms as Arnold and Sons, the Holborn Surgical Instrument Company, Down Brothers, Mayers, and Meltzer had furnished good stalls.

Medical literature was somewhat scantily displayed. Messrs. E. and J. Griffiths, of Swansea, made a capital display, including a good selection of the publications of Messrs. Ballière, Tindall, and Cox, and on this stall we noticed a large number of copies of The Medical Press and Circular. Cassell and Company, Rebman, H. K. Lewis, and W.B. Saunders and Company, also displayed their publications.

Among other interesting exhibits reference may be made to the good show of bedsteads by the Longford Wire Company, of Warrington, and the well-known Lawson's "Tuff" spring beds, made by Messrs. Geo. Gale and Sons, of Birmingham. The O'Connor Extension Company demonstrated their specialties for the lame. The Sanitary Wood Wool Company also exhibited their now widely-known preparations. Mr. Harry Cox had a splendid display of his X-Ray outfits. Ronuk, Limited, also showed their sanitary polishes now so much used in hospitals.

Special Correspondence.

We do not hold ourselves responsible for the opinions of our correspondents.

[FROM OUR SPECIAL CORRESPONDENT.]

BELFAST.

Opening of the Royal Victoria Hospital.—On Monday, the 27th inst., his Majesty King Edward, accompanied by her Majesty Queen Alexandra and the Duke of York, Princess Victoria, came to Belfast to fulfil several engagements, the principal one being the opening of the new Victoria Hospital, a description of which has already appeared in our columns. The Royal party was received by the Lord Mayor and Mr. and Mrs. Pirrie, and after an address had been read by Mr. Wm. Crawford, Chairman of the Management Committee, several of those prominently connected with the undertaking were presented, including Dr. J. Walton Browne, senior surgeon and Chairman of the Medical Staff, and Wm. Whittle, senior physician. The King heartily replied to the address, and opened the door with a gold key, an inspection of the entire building was made, and one ward named the Clarence Ward by her Majesty, in memory of the late Prince Albert Victor, Duke of Clarence.

Medical and Nursing Staffs.—Some details of the medical and nursing arrangements of the new hospital, which have been made for the care of 300 beds, may be of interest. The visiting staff consists of four physicians and four surgeons, with two assistant physicians and two assistant surgeons for the externs; gynecologist and assistant, ophthalmic surgeon and assistant, and pathologist. In addition to these there are two registrars, medical and surgical, and two assistants of anaesthetics. The resident staff consists of three house surgeons, a house physician, and two resident pupils.
The nursing staff will number about 80. There is a matron, a home sister, a superintendent, a housekeeper, and a house-woman, each of whom will be in charge of a "unit", twelve charge nurses, and nearly 90 probationers.

THE ROYAL VISIT AND THE DUBLIN HOSPITALS.

The following official communication has been received for publication:

"The Castle, Dublin.

"The Lord Lieutenant is commanded by the King to announce that a communication has been received from Lord Iveagh, who wishes to mark their Majesties' visit to Dublin by making a presentation to the Dublin Hospitals. "Lord Iveagh has given to the King the sum of Fifty Thousand Pounds to be divided amongst the Dublin Hospitals—Protestant and Catholic alike—and wishes to include in this the National Hospital for Consumption, Newcastle, which is intimately connected with Dublin, and devotes itself to a work in which his Majesty has himself taken a special interest." "The King, who is well aware of the pressing needs of many of the Hospitals in Dublin, has received this information with great satisfaction, and desires that a representative Committee of five gentlemen should be nominated to distribute this munificent gift, and decide which Hospitals are to benefit, and the amount to be given to each." "Lord Iveagh, thanks to his keen insight into the most pressing of the needs of Dublin, has selected the very best means of commemorating their Majesties' visit. The Dublin Hospitals, one and all, are in need—some of them in sore need—of a helping hand, and Lord Iveagh's most generous donation comes at an opportune moment. We trust, however, that it will be found to be not merely a generous donation on his part, but the forerunner of similar donations from others who are equally capable of assisting in the good work done by the Dublin Hospitals. We are sure that nothing could give greater pleasure to the founder of the Prince of Wales' Hospital Fund, which has done so much for the London Hospitals, as to know that the finances of the Dublin Hospitals had been placed on a more satisfactory basis than they at present possess.

Correspondence.

MENINGITIS IN CHILDREN
To the Editor of The Medical Press and Circular.

SIR,—In June, 1890, you were good enough to publish a Communication I sent you on "The Diseases of the Brain in Infants and Children." The chief object that I had in sending that communication was to raise the question of diagnosis in cases of supposed tuberculous meningitis in children. I gave reasons for thinking that such cases as are described by Dr. Burden in this week's MEDICAL PRESS AND CIRCULAR are not tuberculous.

Having made many post-mortem examinations of cases of meningitis, I had come to the conclusion that only a small number were distinctly tuberculous, and that in the majority of cases the symptoms are due to some inflammation, purifying, or septicaemic or other causes. Yours faithfully,

ROBERT LEE.

Trinity College, Dublin—Trinity Term, 1905.

GALTON'S LIFE HISTORY ALBUM. (a)

Mr. Francis Galton's numerous studies regarding anthropological problems, and his valuable investigations into the mysteries of natural inheritance and the unravelling of family characteristics, has peculiarly fitted him for the difficult office of counsellor in such matters. Mr. Galton is no mere enthusiast, carried away by the fascination of academic research, but a serious student of the human desires that the observation of the past shall make us wise in the future. We commend this admirable Life History Album to all physicians, philosophers and patriots. We should like every practitioner to possess a copy, and each family doctor might well induce all rational parents coming under his guidance to purchase one also. Every child has to study the genealogy of historical characters at school, and almost every man and woman delights to detail the pedigree of horse, dog, or other animal pet, but most scientifically-minded individuals know little of their ancestors, and make no serious study of the lives they have been instrumental in launching on life's swift-flowing river. Mr. Francis Galton's Life History Album goes far to stimulate and encourage a serious and continuous study of mankind. The work is arranged to contain a life record. At first the parents are to be the recorders, but later the individual may continue the task of the life's self-improvement. Provision is made for the entering of details concerning genealogy, family characteristics, description of child at birth, particulars of weight and stature, medical history, anthropometric observations, and the preservation of photographs and fingerprints.

In an appendix is provided tests of vision, and a series of charts for the registration of various features. It would be easy to dwell on the humorous and pathetic side of life inevitably associated with such work as Mr. Galton desires to be carried out: and many, no doubt, will take exception to some of the suggestions here given, and may even disapprove of the practice as likely to stimulate or arouse morbid introspection, but we consider that any and every effort which, based on rational and scientific ground, seeks to secure a more reasonable and thorough study of the human subject deserving of approbation and support, and we have, therefore, no hesitation in commending Mr. Francis Galton's Life History Album to our readers.

ELEMENTS OF BACTERIOLOGICAL TECHNIQUE. (b)

This is a technical guide to the application of the various methods of the study of bacteria and their life history. Only methods which experience has shown to be trustworthy, even in the hands of beginners, are described, and the author has endeavoured to present the elements of bacteriological technique in their logical sequence. Recognising the superior educational value of diagrams over mere descriptions, the author has provided a generous supply of illustrations, most of which have been prepared expressly for this work. The literary style is concise in the extreme, and the directions are as brief as is consistent with lucidity. The work has been arranged to allow of its use as a laboratory guide by the technical student generally, in that he may be enabled to select the work of dairying, agriculture, &c. There is, however, a special chapter on pathogenic bacteria for the benefit of medical and dental students.

We have nothing but praise for the way in which the author has acquitted himself of his task. He has

covered the whole ground "up to date," and it is well printed on stout paper.

Obituary.

DR. J. IVOR MURRAY.

Dr. J. IVOR MURRAY, late colonial surgeon of Hong Kong, whose death is announced as having taken place at Addison Mansions, was educated at the University of Edinburgh, and was admitted a licentiate of the Royal College of Surgeons there in 1845, and a Fellow in 1856, taking also in the same year the M.D. degree. Twenty-five years later he was admitted a member of the Royal College of Physicians, Edinburgh. Dr. Ivor Murray was an Army Staff Surgeon in the Crimean War, for which he had the Crimean and Turkish medals with clasps, and was afterwards colonial surgeon, a magistrate, and inspector of hospitals at Hong Kong from 1859 to 1870. He had held several public appointments in Edinburgh and Scarborough, where he practised for some time, and had been a member of several learned societies. He had been decorated by the King of Italy and Sweden with the Order of Merit for assistance to scientific expeditions in the East. Dr. Murray had done considerable literary work. He was the author of the "Catalogue Raisonné of the Military Surgery Museum in Edinburgh University," and he had contributed to the professional journals papers on the "Meteorology and Climate of China," on "Scarborough as a Health Resort in Phtiosis," &c.

Laboratory Notes.

ALLSOPP'S LAGER BEER.

We have had occasion to examine various samples of Allsopp's Lager Beer, which we have no hesitation in describing as a light alcoholic beverage, pleasantly flavoured, and manufactured from sound materials. Owing to the absence of preservatives, it is free from the mawkish taste which characterises many imported lager beers, and it may therefore safely be assumed to be free from the undesirable physiological effects which are associated with the habitual ingestion of chemical antiseptics. It is an ideal beverage for the warm season, containing as it does only 4½ per cent. of absolute alcohol per volume. Analysis gives 4½ grains of extractive per hundred cubic centimetres and 0.25 per cent. of ash. These results are in accordance with the recognised composition of a well-brewed lager beer. It has a delicate flavour of hops, and the product is one which testifies to skilful brewing, so that it can with advantage be recommended as a summer beverage and as a light, mildly-stimulating drink with meals.

Swiss Milks.—In our analytical report of "The Cow's Head Brand," last week, the proportion of 13.3 given as milk and sugar should be read as "milk-sugar."

August 2nd, 1903.

The Medical Injuries and Accident Society.

The usual monthly meeting of the Executive Committee of the Medical Society, Accident, and Life Assurance Society was held at 429 Strand, London, W.C., on the 24th ult. There were present Dr. de Havilland Hall, in the chair; Dr. J. F. Allan, Dr. M. Greenwood, Dr. A. J. Rice Oxley, Dr. Walter Smith, Dr. J. W. Hunt, and Dr. Fredk. S. Palmer. The Committee had presented them the accounts for the first six months of the year, showing that, although the amount paid for sickness claims was large, it was somewhat less than in the corresponding period of last year. As the number of members entitled to sickness benefits grows, the expectation of sickness is present in many cases, and it is therefore satisfactory to find that the amount paid in the first half of this year, £4,860, is about 100 less than in the first half of 1902. The number of members is still increasing; in fact, during the last six months more proposals for new members have been received than in any previous half-year of the Society's operations. The economical manner in which the Society's business has been carried on enables the Committee to offer terms to the members of the medical profession distinctly more liberal than can be obtained elsewhere. Prospectuses and all particulars on application to Mr. F. Addiscott, Sec., Medical Injuries and Accident Society, 33 Chancery Lane, London, W.C.

University of Durham College of Medicine, Newcastle-upon-Tyne.

During the last twelve months there has been a slight decrease in the number of specimens examined in the Bacteriological Diagnosis Department of the University of Durham College of Medicine, Newcastle-upon-Tyne. Some of these examinations have been made for medical practitioners, others by special arrangements for the County Council of Northumberland and Durham, the Guisborough Combined District Councils of the North Riding of Yorkshire, the Town Councils of Sunderland and West Hartlepool, the Newcastle Royal Infirmary and other public institutions. The total number of specimens examined in the laboratory during the year ending May 31st, 1903, amounts to 938, as compared with 1009 during the preceding twelve months. The different kinds of examinations carried out were as follows:—113 samples of sputum from suspected cases of phthisis were examined for tubercle bacilli, which were found in 218 cases; 101 specimens of blood were examined from suspected cases of enteric fever by Widal's method, a positive result being obtained in 44 cases; 205 swabs from suspected cases of diphtheria were examined for the bacilli, which were found in 66 specimens; 10 specimens of pus were examined, the pneumococcus being found in 2, streptococcus pyogenes in 3, staphylococcus pyogenes aureus in 4, and the gonococcus in 1; tubercle bacilli were found in 1 specimen of urine, and in 1 of pus. Seven swabs of exudate of anthrax were examined, positive results being obtained in 4; 50 samples of water were examined quantitatively for bacteria.

Sale of Practice Dispute.

An action was tried in the King's Bench Division on the 30th ult., in which Dr. Houchin, of Ifford, claimed the sum of £978, the balance due on the sale of his practice from Dr. John Marsham. The defence was based on alleged misrepresentation as to the value of the practice and the improving condition of the neighbourhood. Ultimately, however, a settlement was arrived at out of court, by which the French call an échange de bons procédés.

The Royal University of Ireland—Meeting of Senate.

At a meeting of the Senate on Friday, July 31st, 1903, in addition to the transaction of routine business, a letter was read from his Royal Highness the Duke of Connaught accepting, on behalf of her Royal Highness the Duchess of Connaught and himself, the Honorary Degrees vested by the Royal University at last meeting. On the motion of Sir Christopher Nixon, seconded
by Judge Shaw, it was unanimously resolved:—

"That the Senate considers that veterinary medicine is entitled to have its claims for University recognition by the University; and that the Standing Committee be requested to take such steps as it may deem necessary to carry out this object." It was ordered that the annual meeting of Convocation should be held on Wednesday, October 14th, at 4.30 p.m.

PASS LISTS.

ROYAL COLLEGE OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

At the July sittings of the above Board in Glasgow the following candidates passed the respective examinations:

First Examination (five years' course).—John Robert Dunn, Holtrby, of Queen's College, Belfast (with distinction); John David Jones and Andrew Downie Macfie, both of St. Mungo's College, Glasgow; Matthew Hamilton Fleming, Anderson's College Medical School, Glasgow; Charles Nyhan, Queen's College, Cork.

Second Examination (five years' course).—John M'Leod, Mungo's College Medical School; Henry Ruddock Morehead, Queen's College, Cork; George Lees Baker, Owens College, Manchester; William Trega, University of Birmingham; Hugh Glass, Trega College; Alistair Henderson, Robert Fothergill, both of Anderson's College Medical School.

Second Examination (four years' course).—Robert Roberts, William Henry Williams, and Edward Wollen Strickland, of the Glasgow School, Alexander Jack Queen's College, Belfast; John Cretin, University College, Bristol.

Third Examination.—Eva Mary Handley and Anne F. Cleaver, of the London School of Medicine for Women; William Noble Walker, of Anderson's College Medical School; David H. Vickery, Queen's College, Cork, and Trinity College, Dublin; Christopher Parker, of the Westminster Hospital School; George Henry Waugh, Owens College, Manchester; Joseph Owens, of the Edinburgh Medical School; John Priestley Newton, St. Mungo's College; Robert Crothers, Edinburgh University and St. Mungo's College.

Final Examination, and admitted Licentiates of the three co-operating authorities.—Alexander Allen, St. Mungo's College (with honours); Robert Calder Blyth, William Douglas Cockburn, Thomas M'Master, Archibald Montaeth Laurie, James Robert Robertson, John Walker, and Alexander Russell Young, all of St. Mungo's College; Robert Cumming, M.A., B.D., of Glasgow University and Anderson's College; Mulvihill Gerety, Ivan Arthur Jackson, Russell Gerald William Adams, and John Gilmour, all of the Edinburgh Medical School; Anne Fenton Cleaver and Margaret Lucy Tyler, of the London School of Medicine for Women; David Hadden Vickery, Queen's College, Cork, and Trinity College, Dublin; Christopher Parker, Westminster Hospital; Thorvald Maurentius Hafden, Royal Frederick University of Christiana; John Martin, of Queen's Colleges, Galway and Belfast, and Charles E. Hargitt, Queen's College, Birmingham, and Sheffield Medical School.

The quarterly examinations of the above Board, held in Edinburgh, were concluded on 25th ult., with the following results:

First Examination (four years' course).—Mr. Leonard Clarke Webster, Tasmania, passed the examination.

First Examination (five years' course).—Of 34 candidates entered, the following 20 passed the examination:—Effie Jemima Cassels, Glasgow; Michael Albert Mimirbain, Trinidad; Thomas Richard McKenna, Queensland; Lester Ernest Ashley-Emile, India; Archibald Davidson, Melbourne; George Edward Walker Henderson, Edinburgh; Lorn Goldhamer, Mauritius; Charles Henry Alderton, Madras; John Scott Ward, county Cork; Leo Murphy, county Cork; Percival Thomas Rutherford, Shipley; Denham Cecil Woods, Hyderbad; Taylor David Murison, India; Herbert Moncrieff Sturrock, Edinburgh; James Haig Johnston, Carnbee (with distinction); Douglas Llewellyn Leith (with distinction); Herbert Charles Orrin, Colchester; Rodolphe Edouard Laurent, Mauritius; James Quinlan, county Cork; and Francis Willoughby Bullock, London; and one passed in Physics, two in Biology, and one in Chemistry.

Second Examination (four years' course).—Of seven candidates entered, the following three passed the examination:—William Murray, Middlesbrough; Henry Gordon Campbell, Dundee; William Patrick Timmon, Navan; and two passed in Anatomy, one in Physiology, and two in Materia Medica.

Second Examination (five years' course).—Of 30 candidates entered, the following 17 passed the examination:—Lester Ernest Ashley-Emile, India; Townley, Thomas Henry, and Henry Agnew; Albert Pascoe, Durban; Walter Damms, Sheffield; Carlo Ferruccio Fiaschi, Sydney; David James Melville Legge, Dundee (with distinction); Patrick Francis Dwyer, Daniel McVey, Thomas M'Laren, Galloway; Kirkaldy (with distinction); Denham Cecil Woods, Hyderbad; Thomas Campbell Dykes, Dumfries; Henry James Gorrie, Glasgow; S. H. Potts, Robert Thomas Aloysius Patchett, Lancashire; Dirck Johannes Neethling, South Africa; Leo Patchett, Lancashire; and Sorabji Jamasi Bhathend, Bombay; and one passed in Physiology.

Third Examination (five years' course).—Of 21 candidates entered, the following 14 passed the examination:—Tom Newman Darling, Reading; William Cooke Renshaw, Cheshire; Gideon Hendrik van Zyl, Cape Colony; Edward Herrick Knowles, Australia; James Ninian Geo, William McMorris, Newfoundland; John James Gillis, county Antrim; Colin Garnery, Preston; Charles Chaves, Bombay; John Douglas Haley, Youlgrave; Sohrab Shapurji Antia, Central India; Narindra Singh Solhi, Punjab; Ramchandra Kashinath Dhuru, Bombay; Reginald William Blackburn and Henry Agnew; Belfast; and two passed in Pathology and one in Materia Medica.

Final Examination.—Of 57 candidates entered, the following 34 passed the examination, and were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P. and S.G.:—John Archibald Turnbull, Guernsey; Michael Joseph O'Reilly, Ireland; John Stock, London; John Samuel Parkes, Manchester; George James Stones, Birkenhead; Benjamin Peter Donald, Victoria; John Samuel McLean, Melbourne; William Edgar Robertson, Ontario; George Morley Arndell Thomas, Maesteg, Glam; Adrien Ernest Emilie Reboul, France; Herbert Fabian Alsop, Melbourne; Adam Wilson Hall, Edinburgh; Harry Armstrong, West Hartlepool; Allan Graham Hurdman, Ottawa; Thomas Bunnell Lewers, Victoria; Charles Stuart Macaskie, Northumberland; Herbert Frederic Walker, Lanucose; William Pearson Cowper, Orkney; Tom Bragg, Whitewean; John Brydon, Hartlepool; Vincent Paul Pereira, Bombay; Richard Henry Cork; Norman Cecil Rutherford, Shipley, Yorks; Angus M. S. Kelso, Arran; Loren Wilson May, Ottawa; Dowlatram Gop Edas Advani, Hyderabad; Thomas John Walsh, Kilkenny; Peter Oswald Jollie, Leslie; Tom Robert Burnham Smith, Rishshaw; Edward Carlow, Aldershot; Lakshmeshankar Morari Bhai, Bhavnagar; Mervan Sorab Irani, Poona; Arthur Neville, Cheltenham; Thomas Gibbons, Mayo; and Frank Hendry Rae, Kincardine, passed in Medicine and Therapeutics; one in Surgery and Surgical Anatomy; seven in Midwifery; and nine in Medical Jurisprudence.
NOTICES TO CORRESPONDENTS.

AUG. 5, 1903.

Appointments.

Braithwaite, E. A., M.R.C.S., Medical Officer of Health, pro tem., of Exeter.

Dr. Archibald, Assistant Surgeon to the Hospital for Sick Children, Great Ormond Street.

Fox, Hume Clayton, F.R.C.S.I., Assistant Surgeon to the Metropolitan Hospital, for operation on children.

Phelps, J. H., F.R.C.S., M.R.C.S. Lond., a Medical referee under the Accidents Acts, 1875-1900, for Southampton, Winchester, and Romsey in County Court Circuit No. St. 12.

HRH The Prince of Wales, King's Commissioner for Public Health, under the Public Health Act, 1900, of the Port of Nelson, New Zealand.

Vacancies.

Salop Infirmary, Shrewsbury.—House Surgeon. Salary £100 per annum, with board, washing and residence. Applications to the Board of Directors.

Salford Union.—Resident Medical Officer. Salary £150 per annum, with furnished apartments and attendance in the Infirmary. Applications to F. Townsend, Clerk to the Guardians, Union Offices, Eccles New Road, Salford.

Susa Hospital, London.—Assistant Surgeon and Anaesthetist. Salary £270 per annum, with board, washing, and residence in the Hospital. Applications to W. H. Otton, M.A., Secretary, Liverpool Stanley Hospital.—Second House Surgeon. Salary £20 per annum, with board, residence, and washing. Applications to Mr. G. B. Bland, Medical Officer, Medical Board.

Clayton Hospital and Wakefield General Dispensary.—Junior House Surgeon. Salary £150 per annum, with furnished apartments and attendance in the Infirmary. Applications to the Hon. Sec., Clayton Hospital, Wakefield.

Lancashire County Asylum, Wigan, Warrington. —Assistant Medical Officer. Salary £250 per annum, together with furnished apartments and attendance in the Asylum. Applications immediately to the Medical Superintendent.

Southwark, London.—Assistant Medical Superintendent. Salary £300 per annum, with furnished apartments, board, and washing. Applications to Howard C. Jones, Clerk, Union Offices, 10, Southwark Bridge, Blackfriars, S. T. Lee, Secretary.

The Queen's Hospital, Birmingham.—Two House Surgeons. Salary £120 per annum, with board, washing. Applications to the Secretary, Arthur Holme, Secretary, Ramsgate General Hospital and Seaman's Infirmaries and the Ramsgate and St. Lawrence Dispensary. Resident Medical Officer. Salary £100 per annum, with furnished apartments, board, and attendance. Applications to the Secretary of the Dispensary, Ramsgate. University College and Monmouth Wales and Monmouth College of the University of Wales.—Professor of Anatomy. Salary £250 per annum. Applications to J. Austin Jenkins, A., Registrar, University College, Cardiff.

Royal Berkshire Hospital.—House Physician and a House Surgeon. Salary £300 per annum, with board, lodging, and washing. Applications to the Secretary.

Borough Hospital, Birkenhead.—Junior Male House Surgeon. Salary £300 per annum, with board and washing. Applications to the Secretary.

Marriages.

Baker—Hindley.—On July 30th, at St. Mary’s Church, Westminster, to Miss Elizabeth May, youngest daughter of the late Charles H. Hindley, of Allenby Park, B.E.

Humphreys—Lonsbury.—On July 30th, at St. Peter’s, Eaton Square, Rev. Alfred Thomas Humphreys, Vicar of Crouch End, to Miss Ethel Sophia, only daughter of Dr. Arthur Humphreys, of 20, Lower Belgrave Street, Eaton Square, London.

Knight—Hatton.—On July 30th, at Parish Church, Edwinstowe, to Miss Mabel Mary, daughter of Mr. and Mrs. W. Hatton, of Bonsall, Notts.

Mackay—M’Conich.—On July 30th, at the Parish Church, Bochlyvie, to Miss Blair Fraser Mackay, M.C., daughter of the late Mr. William M’Conich.

Morison—Mathews.—On August 1st, at St. George’s, Hanover Square, London, W., to Miss Helen Morgan, M.D., of 11, Brook Street, to Henrietta Frances, youngest daughter of the late Mr. G. H. Matthes, J.P., of Bournemouth.

Deaths.

Bower.—On August 2nd, at 126, Sutherland Avenue, W., to Miss Mary Alexander, in her 90th year.

Operations.—Metropolitan Hospitals.

WEDNESDAY—St. Bartholomew’s (1.30 p.m.), University College (2 p.m.), Royal Free (2 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. Thomas’s (3 p.m.), London (5 p.m.), King’s College (5 p.m.), St. George’s (6 p.m.), National Orthopaedic (7 p.m.), Great Northern Central (7.30 p.m.), Samaritan (8.30 a.m. and 2.30 p.m.), Gt. Ormond Street (8.30 a.m.), Gt. Northern Central (8.30 a.m. and 2.30 p.m.), London (8.30 a.m. and 2.30 p.m.), Samaritan (8.30 a.m. and 2.30 p.m.), Thames, Golden Square (8.30 a.m.), Guy’s (1.30 p.m.), Methodist (2 p.m.), Alderney (2 p.m.), St. Mary’s (2 p.m.), Middlesex (3 p.m.), Soho Square (2 p.m.), North-West London (2 p.m.), Chelsea (7 p.m.), Great Northern Central (8.30 a.m.), Metropolitan (8.30 a.m.), London (8.30 a.m.), St. Mary’s (5 p.m.), Samaritan (8.30 a.m. and 2.30 p.m.), Thames, Golden Square (8.30 a.m.), Guy’s (1.30 p.m.).

FRIDAY.—London (7 p.m.), St. Bartholomew’s (1.30 p.m.), St. Thomas’s (3.30 p.m.), Guy’s (1.30 p.m.), Middlesex (3.30 p.m.), Charing Cross (3.30 p.m.), St. George’s (3 p.m.), King’s College (5 p.m.), St. Mary’s (5 p.m.), Gt. Ormond Street (8.30 a.m.), Gt. Northern Central (8.30 a.m. and 2.30 p.m.), Soho Square (2 p.m.), Southwark (8.30 a.m.), City (8.30 a.m.), Alderney (2 p.m.), St. Mary’s (2 p.m.), Middlesex (3 p.m.), Soho Square (2 p.m.), North-West London (2 p.m.), Chelsea (7 p.m.), Great Northern Central (8.30 a.m.), Metropolitan (8.30 a.m.), London (8.30 a.m.), St. Mary’s (5 p.m.), Samaritan (8.30 a.m. and 2.30 p.m.), Thames, Golden Square (8.30 a.m.), Guy’s (1.30 p.m.).

SATURDAY.—Royal Free (9 a.m.), London (5 p.m.), Middlesex (10 a.m.), Charing Cross (1.30 p.m.), St. Thomas’s (2.30 p.m.), St. George’s (2.30 p.m.), St. Mary’s (2.30 p.m.), Middlesex (2.30 p.m.), Samaritan (2.30 p.m.); (Physician), Soho Square (2 p.m.), Royal Orthopaedic (2.30 p.m.), Soho Square (2.30 p.m.), Thames, Golden Square (8.30 a.m.), City (8.30 a.m.), Alderney (2 p.m.), St. Mary’s (2 p.m.), Middlesex (3 p.m.), Soho Square (2 p.m.), Southwark (8.30 a.m.), City (8.30 a.m.), Alderney (2 p.m.), St. Mary’s (2 p.m.), Middlesex (3 p.m.), Soho Square (2 p.m.), Thames, Golden Square (8.30 a.m.), Guy’s (1.30 p.m.).

MONDAY.—London (7 p.m.), St. Bartholomew’s (1.30 p.m.), St. Thomas’s (2.30 p.m.), St. George’s (2.30 p.m.), St. Mary’s (2.30 p.m.), Middlesex (2.30 p.m.), Westminster (2 p.m.), Samaritan (2.30 p.m.); (Physician), Soho Square (2 p.m.), Royal Orthopaedic (2.30 p.m.), Soho Square (2 p.m.), Thames, Golden Square (8.30 a.m.), City (8.30 a.m.), Alderney (2 p.m.), St. Mary’s (2 p.m.), Middlesex (3 p.m.), Soho Square (2 p.m.), Thames, Golden Square (8.30 a.m.), Guy’s (1.30 p.m.).

TUESDAY.—London (7 p.m.), St. Bartholomew’s (1.30 p.m.), St. Thomas’s (3.30 p.m.), Guy’s (1.30 p.m.), Middlesex (1.30 p.m.), Westminster (1 p.m.), St. Mary’s (1.30 p.m.), Soho Square (1.30 p.m.), St. George’s (1.30 p.m.), St. Mary’s (1.30 p.m.), St. Mark’s (1.30 p.m.), Thames, Golden Square (8.30 a.m.), Royal Ear (8.30 a.m.), Samaritan (8.30 a.m. and 2.30 p.m.), Thames, Golden Square (8.30 a.m.), Soho Square (8.30 a.m.).
Original Communications.

A CASE OF ANEURYSM OF THE ABDOMINAL AORTA TREATED BY THE INTRODUCTION OF SILVER WIRE, WITH A DESCRIPTION OF INSTRUMENTS INVENTED AND CONSTRUCTED BY MR. G. H. COLT TO FACILITATE THE INTRODUCTION OF WIRE INTO ANEURYSMS, by D'ARCY POWER, M.A., M.B., Oxon., F.R.C.S., Assistant Surgeon at St. Bartholomew's Hospital, etc.,

AND

G. H. COLT, B.A.

The patient, a farrier, aged 29, was accustomed to perform heavy work in a stooping position. He had acquired syphilis at the age of seventeen, but had only been treated with mercury for a short time. Three and a half years ago he first noticed something beating in the right side of his abdomen, and since that time he had been continuously under treatment in some hospital or infirmary. On five occasions he received injections of gelatine in the gluteal region, but they had not produced any marked change in the swelling, which increased in size.

On examination he was found to be a sallow, unhealthy, and anemic man, addicted to morphia. His heart and lungs were reported to be normal. His pulse was regular, but poor in volume, and the radial arteries felt thickened. There was a throbbing area of skin in the epigastric and upper part of the umbilical region, which, at its highest point, seemed to be raised about three-quarters of an inch above the level of the surrounding skin. The throbbing was expansile in character, and there was a well-marked bruit, which persisted when the patient was examined in the knee-elbow position. The pulse in the femoral arteries was equal and synchronous. The swelling was diagnosed as an abdominal aneurysm, and more probably aneurysm of the celiac axis, or of one of the branches, than of the abdominal aorta.

The sac of the aneurysm was very thin at one or two points, and as the life of the patient seemed to be in danger, it was decided to expose the sac, and either ligature the artery from which the aneurysm arose, or, if this were impracticable, fill the sac with silver wire.

When the operation had been decided upon my attention was drawn to the fact that Mr. G. H. Colt, one of my dressers in the Throat Department at St. Bartholomew's Hospital, had devised and made an instrument for this purpose. When I had seen the instrument I immediately decided to use it in preference to the more usual method.

I cut down upon the most prominent part of the swelling until an exposure of the sac showed that it would be hopeless to ligature the artery, as the sac was densely adherent to the surrounding structures. No coils of intestine lay between the parietal and visceral layers of the peritoneum in front of the aneurysm. I determined, therefore, to wire the sac, and eighty inches of silver wire, with a clotting surface of 37 square inches, were rapidly introduced into the aneurysm by means of the new instrument (described later as Instrument No. 1). The needle was then withdrawn, the wire was divided, its end was bent up and it was pushed into the sac, the whole being easily closed with a few Lembert's sutures. The operation lasted thirty minutes from the time the patient was placed upon the operating table until he was removed. The actual introduction of the wire only took two and a half minutes, but even this time might be shortened on a future occasion. The pulse during the operation was 88 and the respiration 20. The operation was performed at 4 p.m., and the patient had a quiet night after a hypodermic injection of morphia at 10.30 p.m. On the following morning (January 21st) his abdomen was soft, his respirations were 18, and his pulse-rate was 136. He complained of abdominal pain over the aneurysm and of pain in his back. A second hypodermic injection of morphia was given at 10 a.m., and the patient then slept quietly for several hours. At 2 p.m. the pulse was 135 to 144, and at 7 p.m. it was 146. He ordered two draughts of milk and water every hour, and he was kept under the influence of morphia. There was no evidence of gangrene, nor did he complain of any numbness or tingling in the legs. At 9 a.m. on January 22nd the patient was complaining of pain in his back, his pulse was 160, and his temperature was 101° F. The wound was dressed; it looked healthy. The abdomen was tender, resonant, and showed impaired movement. The right side of the aneurysmal swelling was hard, and did not pulsate, but there was distinct pulsation on the left side. The patient was now taking an ounce of milk and water every hour, and he was reported to have vomited twice, bringing up a small quantity of "coffee-ground" substance the first time, and half an ounce of bile-stained fluid on the second occasion. He still complained of pain in his back, his pulse increased to 170, and he gradually sank, dying at 6.20 p.m. on January 22nd, 1903, about fifty hours after the operation.

The post-mortem examination showed that an aneurysm of the size and shape of a large orange projected forwards from the abdominal aorta between the layers of the transverse mesocolon. The sac was somewhat compressed laterally, and was developed from the aorta itself, the dilated portion of the vessel being about three inches in length, and extending downwards from just below the diaphragm. The great omentum immediately below the greater curvature of the stomach had been torn through at the time of the operation to reach the anterior surface of the sac. On cutting across the aorta just above the diaphragm, a loop of silver wire seven inches long was found projecting into the arch of the aorta, but the rest of the wire was irregularly coiled within the sac of the aneurysm. All the other abdominal organs were healthy; the lungs were normal, and the heart was free from disease, except that the pericardium was adherent in places. The aneurysm and aorta were hardened in formalin before a section was made.

There is nothing particularly new in the treatment
of aneurysm by the introduction of wire, and I should not have ventured to bring this case before the Fellows of the Society unless I had thought that the apparatus invented by Mr. Colt was sufficiently novel and useful to make it worth while to draw special attention to it. Hitherto the surgeon has been content to puncture the aneurysm with a fine trocar and cannula; he has then withdrawn the trocar and forced the wire through the cannula, from which blood was often flowing with considerable force. The amount of wire introduced in this manner has varied with the time at which the occurrence of kinking arrested its further progress. For this reason it has sometimes only been possible to introduce a few inches when it was intended to have put in several feet. The introduction of wire through a cannula is open to the further objection that a great deal of handling is necessary by the surgeon and his assistants, so that it is difficult to ensure that the wire last introduced shall be as sterile as that first used.

The factors in the construction of a new instrument were set out as follows:—

1. The instrument must be self-contained—that is to say, it must carry the wire on the reel, and have some form of fine cannula through which the wire is to pass.

2. It must remove the wire from the reel and introduce it with some force through the cannula, yet without permitting it to kink.

3. It must not allow the wire to damage the sac or the surrounding tissues, although some force has to be used in the introduction of the wire; in other words, the coil must be such that it will pass into the sac.

4. It must be simple in construction, and so easy to work that no instrumental complication may occur during the actual operation, and it must necessarily be capable of withstanding prolonged boiling.

5. It should, if possible, "snag"—that is to say, knot or roughen the wire, so as to be more likely to be promoted by such roughening.

**Instrument I.**—After a few preliminary experiments and considerable trouble, I meet these requirements. The instrument works on a principle which may be enunciated in the following terms. If what is known to the mechanical engineer as a milling tool be made to revolve at a distance less than the diameter of the coil employed from the inner surface of the dorsal wall of a hollow needle, the ventral wall of which has been cut away, the milling tool will grasp the wire between itself and the needle, and wind it off a reel and drive it through the needle with a force only limited by the force at the disposal of the operator. It will at the same time "snag" or mill the wire (Instrument I., Fig. 1). To carry out this principle a quarter-curved tubular needle was embedded for about two inches of its length in the substance of a brass carrier. A semicircular incision was then made down to it through the brass, so that the incision could be used for the needle, and was exposed. A milling tool was introduced at this spot to compress the wire with a steady grip as it passed through the needle, the pressure being made between the milling tool and the dorsal wall of the needle, and care was taken that no space should exist in which the wire could kink. The mounting of the needle was then bolted to the mounting which carried the milling tool, which was then so formed up as to give the operator a room to use the instrument without getting his hands too near the wound. A second hole was made into the tubular needle distal to the milling tool, and along this a stilette is passed to block the point of the needle whilst it is being pushed into the sac of the aneurysm. The instrument is further provided with a handle by which to hold it, and with a second handle which, when turned, causes the milling tool to revolve.

The method of use is as follows:—The aneurysm is punctured on the right-hand side, the stilette is withdrawn, and blood flowing through the needle shows that the point is lying in the sac. The handle through which the milling tool is geared up is then turned in the direction of the arrow engraved upon it, and the wire is wound steadily and rapidly through the quarter-curved needle. The wire emerges into the aneurysm in a coil measuring one and five-eighths inch in diameter, the wire increasing spirally from right to left so as to produce a loosely formed spring. The wire is milled as it passes under the milling tool on the axial surface of the spiral, the coils of which are parallel and one-eighth of an inch apart. This arrangement of the coils is ensured by slightly curving the needle in a plane at right angles to the axis and to the plane of the quarter-curve. Five turns of the handle introduce two complete coils of the wire, the length of which is approximately ten inches, and the clotting surface at least 0.46 square inch. It is evident, therefore, that, although the point of the needle is out of sight, a fairly correct estimate can be made of what is happening within the sac of the aneurysm. When a sufficient quantity of wire has been introduced the needle is withdrawn, the wire is cut, is looped upon itself—to prevent the sharp end from injuring the sac—and is pushed into the aneurysm. The hole in the sac is afterwards closed by a few point sutures.

The use of this instrument in the case narrated at the beginning of the paper shows that although it was not used to the best advantage, it would have been more satisfactory if it had been substituted for the wire instead of being used in conjunction with it. The best method of preventing such an accident on another occasion would be to introduce the wire so that the coils are not all in one piece. This can be done by dividing the wire into sets of coils, a method which has the further advantage of diminishing the ever-in-

---

**Diagram to illustrate the general principle of Instrument No. 1.**

creasing resistance to its introduction. It does not seem possible to make one length of wire push the previous length through the needle into the sac, partly because the wire is too fine, partly because it does not exactly fill the needle when it has been milled, and partly because it is inconvenient to feed a needle with detached lengths of wire. As a matter of experiment, when such an attempt is made the two sections either jam in the needle or the hinder piece of wire kinks. The only alternative, therefore, seems to be to cut the coils as they leave the eye of the needle, and this must be done without withdrawing the needle from the sac of the aneurysm. The wire can be divided in several ways, but the method now to be described seems to be the simplest and most practical.

INSTRUMENT II.—The second instrument (Fig. 2) differs in many important points from the first instrument. There are no gear-wheels, and the milling tool is driven direct. The needle is sufficiently long to remove the mechanism to a distance from the wound. Lastly, the instrument is able to take a thinner wire and a stilette is not required. The coils are divided by the following mechanism (Fig. 3):—The hollow needle (Fig. 3, x) along which the wire travels is encased in a second needle (Fig. 3, x, 2), which exactly fits it. The end of the inner needle is completely block up by a minute inclined plane made of steel (Fig. 3, x, 1, and y, 1), which is securely brazed in position, and is so arranged that it faces the oncoming wire. A lateral opening is made through both needles at their distal ends, and in such a manner that an eye is made with the depressed edges seen in the better kinds of Jacques’ rubber catheters. When the two hollow needles are accurately adjusted (Fig. 3, x) the lateral opening is continuous from the inside of the inner needle to the outside of the outer needle, and through this opening the wire is directed by its impact on the inclined plane (Fig. 3, x, 1), which blocks the end of the inner needle. The tube of the inner needle is soft and flexible, except at the eye, where it is tempered. The outer needle is quarter-curved, tempered throughout, and pointed (Fig. 3, y, 2). The inner needle adapts itself to the curve of the outer needle in all relative changes of position. The outer needle is attached to a rack and pinion placed close to the hand of the operator, and a movement of the pinion causes the outer needle to slide over the inner needle (Fig. 3, y). The relation of the lateral eye of the outer tube to the lateral eye of the inner tube is thus altered, and, by the position of a stop on the rackwork the operator knows the relative position of the two eyes, even when they are hidden from his view. The alteration in the two parts of the eye is sufficient to divide the wire, which may thus be guillotined wherever and as often as the operator chooses. The pinion is reversed when the wire has been divided, and a fresh series of coils can be introduced into the sac of the aneurysm.

The wire employed is No. 27 on the standard wire gauge, and is 0.0164 inch in diameter, or rather less than half a millimetre across. It is soft annealed silver wire, and is supplied by any large firm of wire-drawers at six shillings an ounce of about twenty-two yards. It is
flattened by passing under the milling tool, and it is then 0.0315 inch in width and 0.0145 inch in thickness; and it has a slightly increased surface area, the surface area of the original wire being 5.152 square inches per length of 100 inches. It is exquisitely flexible after it has passed under the milling tool, and easily bends in the plane of the coil, though it is relatively rigid to stresses in any other plane. It is hardly possible to imagine it causing any damage inside an aneurysmal sac, and it is in the highest degree unlikely that it could pierce the wall. The diameter of a coil is three and a quarter inches, but a coil readily adapts itself to the wall of a cavity smaller than itself.

With this instrument ten turns of the handle introduce two complete coils of wire, or a length of twenty inches. When the instrument is used to wire a large aneurysm five turns of the handle should be made before the wire is guillotined, for if fewer turns are made less than a coil is introduced, and when small pieces of wire are allowed to sink in the sac of an aneurysm there is a danger, that they may be brought out into the general blood-stream with unsatisfactory results.

FIG. 4.
Diagram of ideal arrangement of expanding cage.

FIG. 5.
Diagram of actual arrangement of expanding cage. It can be compressed to its diameter at the central part (A), and after traversing a fine cannula will expand again.

INSTRUMENT III.—Another method of wiring aneurysms consists in the introduction of one or more cages of steel wire. The cages can be compressed into a cylinder which can be easily passed through a fine cannula into the sac of an aneurysm, when they immediately expand in the manner shown in Fig. 5. The model when compressed is five inches in length and one-sixteenth of an inch in diameter. It consists of thirty wires, each measuring 0.008 inch in diameter and five inches in length. The cage when it is expanded fits a sphere three inches in diameter, but it can be made to any size. The total surface area of each cage is as nearly as possible two and a half square inches, which is almost equivalent to fifty inches of the silver wire used in Instrument II.

The cage is compressed when it is to be used, and is inserted into a cylindrical tube or cartridge which exactly fits a collar on the cannula employed to traverse the sac of the aneurysm. The cage is expelled from the cartridge through the cannula into the aneurysmal sac by pushing it home with a wire ramrod. More than one cage can be introduced if it is thought desirable to increase the clotting surface, but when a process of active clotting is once started in an aneurysm it is usually progressive, and there is some danger that the second cage may push the first one into an undesirable position. An ideal wire cage of a spherical shape is shown in Fig. 4, but it is difficult to make and unsatisfactory in action. Fig. 5 is a diagram of the actual arrangement adopted, but an objection to it is that the second half of the cage does not expand until it is completely freed—that is to say, until the first half has moved onwards about two and a half inches from the end of the cannula. This might lead to forcible damage to the opposite wall of the sac by the half already introduced. It can be prevented by using only a half cage or "wisp," which, having completely expanded after traversing the cannula, is at once set free in the sac. Experience may suggest different forms of wire cage, but for the present the wiring of aneurysms by means of Instrument II appears to be the more satisfactory method, care being taken not to introduce too great a length of wire.

FOREIGN CLINICAL LECTURES.

ON THE CLINICAL IMPORTANCE OF THE ESTIMATION OF IRON IN THE BLOOD.

By Dr. L. BARD,
Professor of Clinical Medicine at the Faculty of Medicine of Geneva.

The variations in the quantity of hemoglobin in the blood, ascertained by means of the colorimetric test, possess unquestionable significance in the clinical study of certain diseases. Excepting a limited investigation, experimental rather than clinical, on the presence of metahemoglobin in the blood consequent on certain intoxications, up to the present time only the quantity of hemoglobin has been taken into consideration by clinicians, and no attention whatever has been paid to the variations in quality. My own observations were prompted by two reasons. To begin with, my attention had been drawn to the fact that in cases of pronounced anemia the globular element is abnormally high this increase could not be satisfactorily accounted for by any increase in the average size of the red corpuscles. I had noticed, indeed, that the colorimetric test of the hemoglobin in such cases presented peculiar difficulty, due, on the one hand, to a contrast of colour, more marked than usual, between the standard solution and the solution of blood, and, on the other hand, to the progressive and rather rapid change in the tint which had for effect to give a higher and higher figure the longer the estimate was delayed.

These peculiarities had already led me to the conclusion that hemoglobin must be subject to variations in its original qualities corresponding to the variations of colour value and the differences observed in the changes.

Moreover, a general idea of the physiological rôle of the tissues founded on my own theory of absolute cellular specificity led me to see in hemoglobin, as in all cellular derivatives, an organised substance which undergoes various stages of evolution incompatible with the stability and fixity of composition generally attributed to it.

My private opinion is that all the tissues of the organism are formed on a common plan comprising, on
the one hand, a fundamental cellular structure which confers upon them their individual existence, but which has no direct bearing on the physiology of the organism as a whole, and, on the other hand, one or several derivatives, formed by cells within their proper coverings, but outside it, which are common to all and whose physiological function peculiar to the tissue from which they take origin, and which represent the contribution of this latter to the collective life of the being of which it is a part. In the blood, the fundamental tissue is evidently represented by the leucocytes, while haemoglobin and the serum are derived substances.

The genesis of the red corpuscles is still a subject of discussion. In the morphological details of their formation, which are, after all, of only secondary importance, but even as to the place where they are formed and the part played by the organs that take part in the formative process. Whatever may be the significance of these divergencies, it is obvious that it is by the haemoglobin that the essential function of the blood is fulfilled, viz., that of absorbing oxygen from the air, and yielding it up to the tissues. Haemoglobin is a blood what chondrin is to cartilage, or ossein to bony tissues. Like these derivatives it cannot be produced forthwith in possession of all its definite physico-chemical characters. It must go through a phylogenesis, or ripening, before it becomes perfect. It seems to me, therefore, that too much attention is lavished on the formation of the red corpuscles, i.e., on the morphological conditions attending the distribution of haemoglobin, and not enough on the formation of the latter body and its progressive development.

Starting with this general idea of general anatomy and the clinical observations mentioned above, I undertook researches with the object of demonstrating the variations in quality, or the variations in evolution, which I anticipated, and also with the view of determining what influence these variations might have, and thus they might assume, in pathological states. This investigation yielded prompter results than I had hoped. In this article I shall only refer to the first important result which I obtained—that of the real clinical value of the quantitative estimate of iron in the blood.

My earlier experiments were performed in my laboratory and in my clinic in conjunction with one of my assistants, Dr. Mallet. It is to him that I am indebted for the assistance which entailed a very small amount of trouble. The details of the clinical observations, the methods of procedure employed, and the figures obtained will be found in his recent inaugural thesis.

The general method adopted in our researches was the determination, in a number of patients, of the quantity of haemoglobin in the blood by making comparative use of the various clinical methods of estimating the proportion of this substance. Since these methods are all indirect and based on one single characteristic, or on only one of the constituent elements of the body, I hope their divergencies will throw into bold relief the variations in quality and evolution which I assumed to be associated with certain pathological conditions.

The methods we employed were the colorimetric test, the spectroscopic test with Hémocotite apparatus, lastly, the estimate of iron by Jollès's method; all of them being methods which can be carried out with a few drops of blood obtained by a prick or by a small incision in the finger or in the lobe of the ear. The estimation of the iron is rather longer and more complicated than the other two, but it is nevertheless a clinical test, since it requires no more blood than the enumeration of the corpuscles, so that it can be resorted to as often as necessary. Moreover, the manipulations it involves are not beyond the ability of students unfamiliar, as yet, with delicate chemical processes. I should have liked to include the oxygen-absorbing capacity of the blood, but I refrained from this latter test, which it entailed, and,
lower in proportion to the increase in the number of white corpuscles.

The real reason of the differences observed between the results of the iron and the colour tests is to be found elsewhere than in the divergence observed in view of the clinical study of the cases in which they are met with. Generally, the iron test has given percentages higher than those furnished by the colour test in simple chlorosis and in post-haemorrhagic anaemia; lower percentages than those of the colour test in every kind of cachexia, tuberculous, cancerous, chronic anaemia, of chlorotic origin or not, associated with a lowering of the general health.

The chlorosis, under the influence of the treatment and in proportion to the improvement obtained, the percentages tend to become equal, that is to say, the iron and the colour tests tend to assume their original proportions, and it is the same in the recuperative stage of haemorrhage.

In cases of intercurrent haemorrhage following on cachectic states, such as cancer or tuberculosis, the proportion of the two results varies according to the stage of the disease; in the days following haemorrhage the results of the iron test exceed those of the colour test. As we get further away from the starting point, they again become equal and end by becoming lower. Simultaneous results were obtained in two rabbits. In one inoculated with tuberculosis, the iron was less; the other, subjected to artificial haemorrhage, showed an excess of iron.

The pathological differences varied according to the subjects, generally from 4 or 5 per cent. to 15 or 20 per cent., the latter being rather frequent and very characteristic; those of 1 to 2 per cent. are negligible. The very high figures mentioned above are rare, but an important fact is that the extremes in the direction of a deficiency of iron are more marked when in excess, for M. Jellinek found as a maximum in excess 21 per cent. and Dr. Mallet 25 per cent., while, as a maximum for the other extreme, the former 53 per cent. and the latter 34 per cent.

Dr. Mallet has observed and has published in his thesis, in addition to the results of the examination of several normal cases under observation, the results of the examination of thirty-three patients and two animals experimented on. The latter estimates were made at the end of March. Since then, a fairly large number of examinations have been made in my clinic, and their results only served to confirm the preceding facts.

We might sum up these results by stating that the iron test is superior to that of colour, that is to say, in comparing the two it furnishes a higher percentage than the latter, in every case of simple anaemia with normal haematopoiesis and an attempt at return to normal conditions. On the contrary, iron is inferior to colour in all cases where "regeneration is absent," consequent upon hindrance to haematopoiesis, by cachexia or grave organic disease. When these two causes coincide and act against each other, the differences are less pronounced and their direction is determined by the predominance of one or the other of the two factors concerned.

The only plausible explanation of these divergencies appears to be that the blood contains normally hemoglobin in various stages of evolution, since the red corpuscles are subject to incessant destruction and regeneration. The proportion of fresh and of perfect hemoglobin is nearly constant in the normal state, and it is this mixture of fixed proportions which is taken as a standard, when the richness in hemoglobin of the blood is measured. Now fresh hemoglobin possesses, from the very commencement of its formation, approxi-

mately its complete amount of iron. Its colouring power, on the contrary, increases slowly, and only attains its highest degree in the last stages of its evolution.

Normally, completely formed hemoglobin predominates in the blood and gives it its usual colorimetric value in proportion to its iron contents.

In the pathological state, when the destruction of the older globules is not compensated by a formation of fresh corpuscles, the proportion of ripe hemoglobin is even greater than normal in respect of young hemoglobin; thus it follows that the colorimetric value is higher than that of the iron. If, on the contrary, anemia is due to the exaggerated destruction of the older corpuscles, and is accompanied by the destruction of fresh corpuscles, the opposite effect is produced and iron predominates over colour.

However this may be, the constancy of the law which governs the significance of the expulsion of nucloids practically observed makes the comparison of these two estimations an important element of diagnosis and a valuable basis for prognosis.

From this point of view, one of the cases studied in conjunction with Dr. Mallet, and reported in detail in his thesis, was particularly striking and singularly instructive. It was a case of pernicious anemia of bothricephalic origin, which subsided on the expulsion of the tenias. On admission the blood showed 1,085,000 red corpuscles per cubic millimetre, 30 per cent. colour and 26 per cent. iron, with a globular value of 1:38; he presented all the usual features of pernicious anaemia. As this case was the first of its kind that I had seen, I had no difficulty in realizing the reality of the part played by bothricephalus in the production of the anaemia.

The administration of five grammes of the ethereal extract of male fern led to the expulsion of three Annelida and three scolices of Bothricephalus laevigatus. Improvement set in immediately and very rapidly; at the same time the hematological formula underwent a change. Eleven days after the expulsion of the tenias, there were two million corpuscles, 40 per cent. colour and 39 per cent. iron; nine days later, 2,800,000 corpuscles, 25 per cent. colour and 40 per cent. iron. The patient had gained four kilograms in weight, and felt so completely cured that he insisted on taking his discharge.

From the first examination after the expulsion of the tenias, the increase of iron, far more rapid than that of colour, indicated the gradual disappearance of the cause which prevented haematopoiesis; by this means the pathogenic role of the tenias was established, and the prognosis immediately became favourable.

In certain cases of chlorosis, especially when the complaint is of abnormal duration and tenacity, it is difficult to say whether the accidents are dependent solely on the intensity of the chlorosis or whether the latter is not caused or maintained by some organic affection of the heart or lungs. The estimate of iron can be utilized to settle this question, since in chlorosis, before the improvement following treatment, the quantity of iron exceeds that of colour by from 10 to 20 per cent. and from 12 to 25 per cent. in the cases studied by Dr. Mallet, When complicated, especially by tuberculosis, the proportion is reversed and the iron remains generally about 10 per cent. above the colour. It is the same in cases of anaemia symptomatic of tuberculosis, with or without a chlorotic character.

The preceding details and examples suffice to show the importance which the estimation of iron in the blood may assume in clinical work, and thus justify the title of this article. We must always bear in mind that we are dealing with comparative values and in no way with absolute quantities. It is possible that the exact quantity of iron contained in the blood may have a special clinical importance in the estimation of states of anemia. We are, in this way, in the appreciation of the state of the hemato poetic energy, a state which in its turn materially assists us in the diagnosis and prognosis of numerous affections.

Many points still await elucidation, for example, the part played by permanent influences, such as age or sex, and that played by accidental or periodical circumstances such as pregnancy or the catamenia. Several
The paramnesic states so common in alcoholic insanity are regarded as being due primarily to the occurrence of an illusion or hallucination, and secondarily, inability to distinguish between what has been a false sensory perception and a perception founded upon an objective reality. Any explanation must depend not so much upon the evidences of illusion and hallucination as upon the existence of a negative lesion which prevents the individual from correcting the false impression. This negative lesion is probably due to disruption of the contiguity of neurons, to consequent failure of the comparing and associative faculty, and to isolation of the contributory processes essential to a proper seriality of thought.

Alcohol per se does not cause general paralysis of the insane any more than it is responsible for tabes. The factor of alcohol when added to that of syphilis does not lead us to modify the diagnosis or prognosis very materially in any individual case, but when alcohol is said to be the sole factor then even the most experienced hesitates to diagnose general paralysis, knowing that probably he may be deceived. In those cases diagnosed as general paralysis due solely to alcohol, and which may have progressed to a fatal termination within the time allotted to general paralysis, the pathological findings are of varied interest and suggestive of etiopathological factors differing widely from the syphilitic types.

Many cases of mania with excitement in which the pupils are contracted, reflexes diminished, muscular tremors followed later by convulsions, when extending over a period of two or three years, are apt to lead to a faulty diagnosis of general paralysis, the conditions being really due to some renal disease or over-production of toxic substances in the body and eliminated in the urine. In spite of the comparative frequency of such symptoms as inequalities of pupils, tongue tremors, alterations and defects of speech, sluggishness or exaggeration of the knee-jerks, and not infrequently hemiplegias, or other symptoms of arterial and cerebral degeneration, in no case uncomplicated with a history of syphilis is there absence of the pupillary reflex to light. In these cases the cerebral degeneration is mainly due to vascular-changes consequent upon kidney diseases.

A NEW FORM OF STERILISED SWABS FOR SURGICAL OPERATIONS.

By J. JACKSON CLARKE, M.B., Lond., F.R.C.S.,
Senior Assistant Surgeon at the North-West London Hospital, and
Assistant Surgeon at the City Orthopaedic Hospital.

The accompanying illustration shows a form of swab designed to meet the requirements of ordinary surgical operations, and more particularly abdominal sections. The swab is triangular in form and consists of absorbent wool everywhere covered with a double layer of soft gauze which is so stitched that no rough edges are exposed and none of the cotton fibre is on the surface, thus reducing to a minimum the amount of cotton fibre that will be left behind in the wound when the swab is removed. At one angle is a pocket into which a finger, probe, or other instrument can be introduced; this greatly facilitates careful packing of a cavity or a large wound during the process of operation. For
instance, in operating for appendicitis it is often difficult to pack in the ordinary square swabs without unduly pressing upon the surrounding coils of healthy intestine, whilst the insertion of the thin-pointed swab by means of the index finger pushed into the pocket can be done without difficulty, and the broader ends are then easily arranged so as to completely isolate the inflamed area. The ordinary process of hemostasis is also facilitated by this form of swab held in the left hand with the tip of the index finger in the pocket of the swab, the remainder of which is held in the palm of the hand. The general surface of the wound being freed from blood by the main part of the treatment of the swab can be pressed by the index finger on any particular vessel, which is secured by forceps on raising the index finger with greater ease than when a large surface with several bleeding points is suddenly exposed. Mr. W. Martindale, 10, New Cavendish Street, London, W., has carried out the preparation of the swabs for me with the greatest care as to cleanliness in manufacture and subsequent sterilisation, after exhaustion of air in water vapour at a temperature of over 230° F. for half an hour in tins, which are soldered immediately on completion of sterilisation. For use the exterior of the tins is cleansed with strong carbolic lotion and then easily opened by unrolling a metal strip.

The swabs are carefully counted and packed in tins of two sizes, containing respectively 10 and 25 swabs. The number of swabs used in any operation is readily ascertained, and the danger of leaving a swab in the wound is thus removed. Any swabs that remain in an opened tin can be safely used as part of or the entire dressing for the wound.

**BRITISH SANATORIA FOR CONSUMPTION.—VII.**

[By our Special Medical Commissioner.]

**THE MOUNT VERNON HOSPITAL, HAMPSTEAD AND NORTHWOOD.**

The Mount Vernon Hospital occupies a unique position among British institutions for the care of the consumptive. It is the only one of any considerable size which provides, without payment, adequate hygienic treatment of pulmonary tuberculosis in accordance with the best sanatorium methods. The hospital is national in character and draws its patients from all parts of the country. The institution consists of three parts: the central offices, lecture-room, library, laboratory and out-patient department, situated at 7, Fitzroy Square, W.; the hospital proper, which is conducted on strict "open-air" lines, beautifully situated at Hampstead, just over four miles from the very centre of London, at an elevation of 300 feet, and close to the health-giving and far-famed Hampstead Heath; and the sanatorium which is nearing completion at Northwood, about fourteen miles from London, with 104 acres of surrounding land peculiarly suitable to the needs of the phthisical subject. Very shortly accommodation will be available for something like 250 cases, with ample provision for very considerable extensions should financial resources allow.

The growth of the institution has been phenomenal. Founded in 1860, it slowly widened its sphere of usefulness till 1898, when, adopting the popular and rational hygienic or "open-air" treatment, the hospital quickly came to the front, and now occupies the foremost position among institutions for the consumptive poor. The problem of meeting the needs of the phthisical cases is one which the authorities of the Mount Vernon Hospital have seriously set themselves to solve. The demands on the hospital, as may be imagined, are enormous. We are informed that 260 "suitable" cases are admitted to the hospital, and these only represent something like 40 per cent. of the cases applying. It is pitiable to find that of these "waiting suitables" only about one-half are able to be admitted when, after four to five months, their time comes for admission. To maintain such an institution open to all needy cases necessarily demands liberal support, and it is pleasing to know that a generous public has not been slow to recognise the good work being carried out, and has freely contributed liberally; but to meet the urgent demands of cases in all parts of the country national support is necessary. The institution is conducted on strictly scientific lines. There is a visiting staff, all the members of which are of consultant rank. There are two resident medical officers at Hampstead, and, it may be supposed, a like number will be provided for Northwood. There is also an excellent nursing school where training in the hygienic management of consumption is provided. In the central offices in London post-graduate lectures and demonstrations are given. The out-patient department is about to be considerably extended. The new balconies at Hampstead are excellent and afford admirable means for open-air treatment. A considerable number of cases are allowed to sleep in a large open tent in the grounds. The sanatorium at Northwood promises to be the most complete and up-to-date in the country. All modern improvements seem to have been secured, and the various buildings are excellently arranged, not only for the convenience of the patients, but for the best and easiest conduct of the establishment. The large dining-room, well-placed winter gardens, separate nurses' home, are features meriting particular praise. The kitchens, laundry and other offices have been so arranged as to allow for future extensions, peculiarly charming little church is being built in the grounds. We were glad to find that arrangements had been made for carrying out scientific work, a convenient laboratory being in course of building. Excellent bath accommodation has been provided. The site at Northwood is admirable, and its proximity to London will be a great convenience both to the visiting physicians and patients and their friends.

Treatment, as far as we can gather, is conducted on strictly rational lines, and rigid adherence to open-air methods is enforced, an abundant dietary is provided for, but forced feeding is not carried out; rest and exercise is strictly regulated by the resident medical officers, and all exercises are carefully graduated.

Admission is obtained by a subscriber's letter, an antiquated and artificial method which we hope the board of management may soon be able to discard, leaving the institution open to all comers and making the physicians solely responsible for the selection of suitable cases.

The honorary staff consists of a consulting physician and surgeon, five physicians, three assistant physicians, a surgeon, laryngologist, anaesthetist and dental surgeon. Duly qualified medical practitioners may be attached to members of the honorary staff in the capacity of clinical assistants. Least of the members of the profession in all parts of the country act as honorary medical referees.

The recently published annual report contains much material of scientific value. A copy of the full particulars of the work of the hospital, may be obtained,
France.

APPENDICITIS AND TAPWORM.

At the meeting of the Société de Chirurgie, M. Martin related a case of a young girl, aged 23, having suffered twice from colic in the region of the appendix, and at the third attack she accepted an operation. After opening the abdomen, the appendix, free from all adherence, was found to be thickened, and in the organ were felt two small calculi. On being resected two rings of the Tenia saginata presenting active movements, attesting its vitality, escaped. The appendix also contained three thread-worms and two scybalae. The operation terminated successfully, and a few days later the tapeworm was expelled through the influence of a tenifuge. The speaker concluded by saying that it was the first example of an appendix containing a tapeworm.

NASAL DYSMENORRHA.

Nasal dysmenorrhea does not signify, as the term would imply, a nasal flux or a vicarious menstruation. According to Professor Barozzi, it is a term created by Fließ to designate a special clinical variety of dysmenorrhea, of which he fixes the point of origin, the primum morbus, in the pituitary membrane; in other words, there existed in certain women suffering from menstrual trouble a direct and intimate relation between the naso-mucous membrane and the uterine apparatus. Moreover, if Fließ is to be believed, the real origin of the genital disturbance known under the name of dysmenorrhea was seated in two special points of the nasal mucous membrane—the tubercle of the septum and the inferior turbinate. To these two points he gave the name of genital zone.

To prove his assertions, Fließ instituted the following experiments:—With a small plug steeped in a solution of cocaine, applied to the two points mentioned, he produced anaesthesia of the membrane. Under the influence of this simple operation, the uterine pain ceased immediately and the patients experienced a bien être which persisted as long as the action of the drug. To obtain a definite cure it sufficed, according to Fließ, to destroy the two genital points by means of cautery or electrolysis.

The publication of these experiments gave rise to numerous researches on the part of certain specialists in order to control the assertions of Fließ, amongst whom were Knorr, Koblanck, and Schiff. The results reported concorded exactly with those of Fließ. According to Schiff, 72 per cent. of the patients suffering from dysmenorrhea were relieved by the cocaine treatment. Later on three distinguished rhinologists, Moll, Sauter, and Linder, renewed the experiment on thirty patients, and in the large majority of the cases the effects of the cocaine application were surprising. The patients seemed enchanted with this new method, and many returned to ask that "something should be done to the nose."

In a word, everything happened exactly as Fließ and his partisans affirmed. However, Linder was not entirely convinced, and undertook new experiments in order to determine what rôle suggestion might have played in the matter. Having selected sixteen patients fulfilling the required conditions, he proceeded to apply a solution of 10 to 20 per cent. of cocaine to the mysterious zones. In four patients there was no attenuation, in two others the treatment seemed to intensify the pain and had to be abandoned, but in the remaining ten the effect was truly remarkable. The pain disappeared as by enchantment; the patients were so surprised that they wanted to know what had happened to them. The relief lasted from a few hours to twenty-four hours. The following day the same patients were treated without their knowledge to applications of pure water. Two of them felt no benefit, two others, immediate relief; and the remaining six experienced a relief of thirty minutes. Cocaine was then used with same success as the previous day. The following day the same patients presented themselves again, and pure water was applied again by Linder, but the patients were made to believe that it was the cocaine solution. To his great surprise, the result was as complete as the first day.

From these experiments Linder was inclined to believe that suggestion was alone capable of operating the miracle proclaimed by Fließ and Schiff, for he could not believe that the action of cocaine on two insignificant points of the nasal mucous membrane could have for direct and immediate result the arrest of such intense and tenacious suffering as that of dysmenorrhea. Such is also the opinion of Professor Barozzi.

VIENNA, August 9th, 1902.

MULTIPLE MYELOMA.

At the Gesellschaft für innere Medizin, Jellinek showed photographs and radiograms of a female patient, aged 47, who came of a healthy family stock, and whose illness commenced about a year ago with pain in the chest and loins, accompanied with occasional rigors and a feeling of weakness. On February 15th, 1903, on making a false movement, the patient broke the right femur, and as motion was performed with great difficulty she broke the left femur on the 20th of the same month.

A careful examination of all her organs revealed a healthy condition of the nervous system, except a slight disturbance in the rougher movements of the muscle. Nothing abnormal could be detected in the heart, lungs, liver, or spleen. In the urine there were albumin and serum albumin as well as a distinct quantity of proteo-albumin, although Bence Jones' albuminoid corpuscles were not present. In the sediment, individual hyaline cylinders and leucocytes were present. The blood contained 50 per cent. of hemoglobin according to Fleischel; erythrocytes, 6,050,000; white blood corpuscles, 30,000. The chief changes present were to be found in the bony structure, and more particularly in the lymphoid marrow bones, diploë of the cranium, and proximal ends of femur and humeri. The bones were shortened, surface uneven, and the general appearance of the osseous structure altered. This irregular external appearance had no many depressions as to give the idea of the bone being absent at the base of these hollows, where the ramification of the structure was profuse. The thorax on this account was quite deformed, and, with the exception of the first rib, every one of them had these deep hollows or depressions in their surface. In the region of the heart, there was a large swelling distinctly pulsating, but at every inspiration the central part was aspirated or drawn. The bones of the pelvis were unchanged, which excluded osteomalacia. The femurs were distinctly shortened, contracted, and bent. The lower parts of the legs and arms, such as elbows, wrists, and fingers, were un-
changed, although all the bones were painful on pressure and movement.

After a species of differential diagnosis by elimination, Jellinek came to the conclusion that in the absence of any primary neoplasm the case was one of multiple myeloma. This opinion, he said, was supported by the skagrams produced, whereas in the cylindrical long bones numerous round, clear centres could be observed, sometimes a number segregated, at other times separately.

Mannaberg remarked that Jellinek's reasoning did not convince him that this case was not one of osteomalacia, as we often had cases where the long bones are attacked, such as the radius, ulna, &c.

Jellinek replied to this by saying that we never find in osteomalacia such foci of neoplasms as are present in this case.

Schlesinger asked if any symptoms of paraplegia were observed in the legs or arms at any time during the progress of the disease. He explained that he asked this question for information, as a very large percentage of multiple myelomata had the paraplegic phenomena owing to compression of some of these centres in the spinal column. He would also like to know if these spontaneous fractures were painful or not.

Jellinek replied that the examination of the spinal cord was purposely avoided lest any other fracture might be produced, while the motility of the lower extremities could not be satisfactorily tested owing to the fracture of both legs. One thing he could confidently say, that the sensibility, both in quality and quantity, was perfectly normal.

He would also add that the fractures were painful.

Acute Lymphomatosis and Tumour Orbita.

Lauber brought forward a case of lymphomatosis, with multiple gland tumours, enlargement of spleen and hepatic and posterior lymphatic glands involving the fibrous lymphatic tissue of the thorax, and hemorrhage into the retina of the left eye.

Weinberger said he had carefully followed this case from an ophthalmic point of view, and agreed in many details to others that had been brought before the notice of this Society. It was a pronounced case of lymphæmia, wherein the neutrophile and eosinophile elements had almost disappeared, while the white corpuscles are made up of large lymphocytes, thus numerically giving the white corpuscles a number very little below the normal. It seems that the lymphoma rapidly increased, accompanied with great weakness, due probably to the acute lymphæmia. This case was most noteworthy on account of the rare form of retrobulbar lymphæmia, and, secondly, on account of the localisation to the mammary glands. Considering the fact that these glandular tumours were everywhere movable and nowhere confluent, that the retrobulbar growth was slow and in no place was attached to the bone, and that the mammary growth was nowhere fixed, excluded altogether from his mind the possibility of a sarcomatous character.

Hungary.

[From our own correspondent.]

Budapest, August 8th, 1903.

At the recent meeting of the Budapest Hospital Society, Dr. Hainiss read a paper on

Ascaris Invasion in a Child, Aot. Six.

The case is not only interesting by reason of the fact that the ascarides occurred in great numbers—no less than 279—but also because they gave rise to very grave symptoms. H. R., the child of a workman, was admitted to hospital on November 16th, 1902, with a history of vomiting for ten days. The child had been restless, had pains in the head and belly, had lost all appetite, and suffered from constipation. His mother attributed this state to his having eaten unripe fruits. The boy, markedly emaciated, lay in bed curled up, or throwing himself from side to side, complaining of abdominal pains. The temperature was 38° C., the tongue coated and dry and the pupils dilated. The abdomen was distended and tender, especially in the region of the gall-bladder. On the 18th and 19th, several ascarides were discharged. On this ground the boy was given on the 20th 20 centigrammes of santoin, whereupon forty-five ascarides were passed, partly through the anus, partly through the mouth and nose during vomiting. On the 21st, after the administration of a copious enema, thirty-six worms, and later ten more, were discharged. On the 22nd, thirty worms, on the 23rd eight, and on the 24th, thirty-one were discharged. The child gave one the impression of being very ill, and the belly was still painful. A few worms were passed daily. More santoin was given on the 29th, when fourteen more worms were passed. On September 30th twelve worms were discharged. Afterwards from one to eight worms were passed daily. On January 3rd, 1903, the last worm was discharged, making altogether 279. The temperature waved between 36° and 40° C. The symptoms improved pari passu with the diminution in the number of ascarides, and the boy left the hospital on January 17th completely cured.

The question suggests itself why so many worms should have formed in the intestinal tract. Shibald's view is generally admitted, according to which ascarides are not propagated within the intestinal tract, but the fecundated ovum must previously undergo a certain evolutionary process and then return into the stomach in order to undergo its evolution in the intestinal tract; otherwise, of the 60,000,000 ova of the ascaris hundreds of ascarides ought to grow. This is of very rare occurrence in our experience, but the invasion is more common in tropical climates, especially among the so-called "dirt-eaters." Thus it may be assumed that the ova ready to undergo their evolution arrive in great numbers in the stomach either in drinking water or with fruit or green vegetables. The author was unable to offer any explanation of the fever and of the pains referred to at the region of the gall-bladder. Thus not every ascaris case passes off without grave symptoms. But Henoch mentions a case where a child had eaten jam mixed with semen cinna, whereas he passed an immense quantity of ascarides without having suffered any particular inconvenience at any time.

Dr. Trinsey asked why the santoin had been given in such a dilatory fashion.

Dr. Hainiss replied that in emaciated and weakly children one must be very cautious in administering santoin, and, on the other hand, he could not foresee that the ascarides were present in such abundance.

Gastro-Intestinal Lymphatics.

Dr. Polya Teno related the experimental results which he had arrived at in the First Anatomical Institute of Professor Leuhossek regarding the lymph vessels of the stomach and appendix. Thirteen new-born infants were examined concerning the gastric, and nineteen concerning the appendical, lymph vessels. With regard to the lymph vessels of the appendix, it was found that they all run towards the regional lymph glands, and eventually discharge into the mesenteric glands, after having usually passed
through several glands intercalated in the appendix. They stand in no anatomical relationship with either the lymph vessels of the lig. latum or with the retro-peritoneal glands.

As to the lymph vessels of the stomach, they found that these, following the way of the blood path, passing through smaller intercalated glands, pour their contents into the gland groups lying in the hilum of the liver at the subpyloric region, close to the trunk of the right coronary artery.

Concerning the importance of the lymph vessels and glands in question, they arrived at the conclusion that while a knowledge of the lymph vessels of the appendix enables us merely to explain some of the rare complications of appendicitis, they have no other bearing. At the same time the knowledge of the passage of the lymph vessels of the stomach enable us to draw a very important conclusion, viz., that lymph paths coming sometimes (also directly) into deeper-lying glands, are on this account to be remedied by radical operations.

The Operating Theatres.

NORTH-WEST LONDON HOSPITAL.

OPERATION FOR REMOVAL OF MALIGNANT DISEASE OF THE GLANDS IN THE FLOOR OF THE MOUTH, INVOLVING THE TONGUE AND LOWER JAW.—Mr. Mayo Collier operated on a man, aged 63, the subject of extensive malignant disease, apparently originating in the floor of the mouth. The patient stated that for the last six months he had had pain, stiffness and difficulty in masticating, which had gradually increased up to the present period. The first indication of anything wrong with the mouth was an increased flow of saliva and some swelling in the right submaxillary region; this was attributed to the presence of a decayed tooth in the right lower jaw, and consequently not much notice was taken of it; the trouble, however, increased, and a definite swelling and hardness could soon be made out between the floor of the mouth and the skin. A previous but distant history of syphilis invited the administration of iodide of potassium; large doses were given for a period of three weeks or a month, apparently without any other effect than that of increasing the patient's discomfort from the flow of saliva. The suspicion of the nature of the case being explained to the patient, and the consequence of necessary operation, and more or less mutilation of the tongue and the floor of the mouth being put before him, he declined to accede to any operation, and relied upon a short change of air to effect a cure. Four or five months subsequently he returned to the hospital, then chiefly complaining not only of swelling of the parts and great discomfort, but also of inability to open the jaw to more than a limited extent. In this interval the disease had made rapid progress; a considerable swelling was now apparent below the right lower jaw; the tissues round the angle and outer surface of the jaw were red, hard and angry-looking, the right side of the floor of the mouth as far as the left incisor tooth was invaded by new growth filling the mouth to the level of the teeth; the tongue was now evidently invaded as far back as its root, and the anterior pillar of the fauces was involved. The extreme seriousness and urgency of the case were laid before the patient, and he consented to have done whatever Mr. Collier thought requisite. It was now apparent that not only the greater portion of the tongue, the floor of the mouth, the right lower jaw, but also all the tissues in the right submaxillary region would have to be removed to ensure a temporary relief to the patient's troubles. Mr. Collier commenced the operation by making an incision as for removal of the lower jaw; skin flaps only were turned upwards and downwards. An incision was next made near the symphysis opposite the left canine tooth, and the saw applied. With the help of saw and bone forceps the lower jaw was divided about an inch and a half below the condyle, and the bone with its diseased tissues removed. The tongue was next grasped by passing a stout ligature through its tip and forwards. Quite two-thirds of the tongue and of the tissues of the floor of the mouth were cut away with curved scissors, and the arteries rapidly picked up as they presented themselves. There still remained a considerable portion of the affected tissue in the lateral wall of the pharynx; this was carefully dissected off with scissors and forceps. The skin was next adjusted and the patient returned to bed, care being taken to keep him lying prone on his right shoulder face downwards so as to encourage natural drainage of the parts. No previous tamponing of the larynx was resorted to, and no difficulty was experienced with the anaesthetic. The anaesthetic employed was chloroform. Mr. Collier said this was one of a number of cases of extensive malignant disease in the neighbourhood of the mouth that he had operated on. In considering the question whether such a case as this should be operated upon or left to its fate, the surgeon had to take into account the misery and suffering that would accrue to the patient before a fatal termination took place. The inability to swallow, the constant pain and the factor from the mouth, rendered life a burden to the patient and a source of extreme discomfort to his friends. The result of the operation he had just undertaken would, he remarked, in this case relieve the patient of the pain, foster and general discomfort, and would, in most cases, prolong life for a period of from six to twelve months. Although in undertaking these serious operations the patient, Mr. Collier said, is exposed to extreme risk, not only during the operation itself, but also subsequently, it was his experience that a large percentage made a rapid and complete recovery and were enabled to enjoy a period of some months of comparative comfort and happiness; moreover, when recurrence did take place it was frequently in sites distant from the original trouble, and death took place from some remote secondary affection. He pointed out that a precaution of great importance in these cases was the proper arrangement of the position of the patient during the operation, to avoid the possibility of blood entering the larynx; to do away with the disagreeable necessity of tamponing the same all that was requisite, he said, was to raise the patient in a semi-recumbent position and incline the site to be operated upon downwards close to the edge of the table; by this means blood gravitated outwards instead of into the pharynx, and the anaesthetic could easily be administered by a tube passed into the nostril of the opposite side; this position, somewhat modified, is resorted to during the first two or three days of the patient's convalescence, and consequently all secretions and drainage from the wound find an easy and natural exit and so help to prevent the common and fatal complication of septic pneumonia. The patient left the hospital fourteen days after operation apparently convalescent, and with surprisingly little disfigurement.

An army tutor died under chloroform at the West London Hospital last week while undergoing an operation for the relief of appendicitis. At the post-mortem examination it was found that an appendicular abscess had ruptured, causing syncope, to which, rather than to the anaesthetic, he had succumbed.
THE CHOICE OF PATIENTS FOR OPEN-AIR SANATORIA.

The enthusiasm with which the open-air treatment of pulmonary tuberculosis has been taken up by the profession and by the public threatens, unless kept within reasonable bounds, to bring the method into discredit. Medical men, and in general those who are in a position to facilitate the admission of a phthisical patient into such institutions, are besieged by applicants on behalf of sufferers in the antepenultimate stage of the disease. The more distressing their condition the greater is the claim they are supposed to have for reception, and the pressure brought to bear by sympathetic but undiscriminating outsiders is with difficulty resisted. Nay, since these institutions are in large measure supported by the public by voluntary contributions or by the payments of patients, the more urgent the circumstances the more solicitous are the applicants. The inevitable result is that hospitals for consumption and sanatorium are to a large extent filled by unhappy patients, whose state no longer justifies the hope of permanent relief, much less of cure. After a time advantage is taken of a temporary amelioration to induce them to return to their homes, where, under unfavourable conditions of environment, they promptly go from bad to worse. Unfortunately, it is easier to point to the consequences of this misapplication of valuable therapeutic resources than to suggest a remedy. It is obvious that hospital and sanatorium treatment, which is curative or nothing, should be reserved for persons who are still at a stage of the malady at which good effects may be confidently anticipated. As a matter of fact, these early cases, being of their nature less urgent, are crowded out by the more advanced cases. Moreover, the patients themselves are often by no means anxious to forego their daily occupations and devote their flickering energies to curative treatment. With the hopefulness which is one of the most remarkable and pathetic features of tuberculous disease in human beings, they are only too glad to shut their eyes to the onward progress of the malady, and positively resent any advice which infers that their state is grave enough to warrant their giving up work and undertaking a prolonged course of treatment. It is not until they have reached a stage at which they are constrained to abandon work, a stage associated with extensive and usually irreparable damage to the pulmonary tissues, that they reluctantly acquiesce in advice, which, if followed earlier, might have enabled them to hold their own. Then, too, it is not sufficiently impressed on patients that a return to the conditions of occupation and environment which produced the disease must necessarily conduce to a relapse. And even when this lesson is learned it must often be beyond the power of the sufferers to control or modify their conditions of life, and the inefficacy of the treatment is ignorantly called into question. The only remedy for this state of things would be for more drastic rules to be made and enforced in respect of the admission of patients. It is indispensable that this question should be left in the hands of the medical officers, especially where municipal institutions are concerned. Moreover, however harsh it may seem, it should be a rule that patients who fail to derive benefit within a certain limit of time should be discharged to make place for those more amenable to treatment. The accommodation for the phthisical is not likely to be commensurate with the demands for many years to come, and it is, therefore, the more necessary to restrict the benefits of these institutions to sufferers whose lesions are not too far advanced to defy curative measures.

"PROTECTION" IN HOSPITAL APPOINTMENTS.

The world of medicine presents to the observant mind a curious mixture of progress and conservatism. The scientific aspects of professional life set forth a fascinating picture of a self-sacrificing and absorbing pursuit of knowledge in the best interests of humanity. At the same time, it is impossible to disguise the fact that there is another and less attractive reverse to the picture. Fortunately, or unfortunately, the medical profession is in the overwhelming majority of cases adopted as a means of livelihood. That being the case, the elements of competition and of class combination become involved to an extent that is hardly recognised at its true value within the walls of the profession itself, to say nothing of the outside public. There are many valuable appointments, paid and unpaid, in connection with hospitals, teaching, schools and universities, the services, and many public and official appointments. It is natural
that an attempt should be made as far as possible to secure the monopoly of these coveted positions by this or that section of the profession. This result is inevitable while the struggle for existence is carried on by society under its present conditions, and can hardly be seriously condemned, although it clearly falls short of any high scheme of social morality. The safeguarding of its interests as a whole is carried out to a most complete extent in the legal profession. In the sister calling of medicine the general defence is notoriously feeble, and indeed the only thoroughly practical existence of the kind is the undeclared class combination that exists among those who are often spoken of as "the leaders of the profession." To a certain extent such common action may be tolerated as the outcome of a reasonable measure of self-preservation. The main body of the medical profession, however, is made up of general practitioners, and it behoves them to keep a careful eye on the movements of all classes or combinations in the profession to which they belong, in order to prevent the inflection of injustice or injury either to themselves or to the outside public. There is one point to which their attention may be emphatically drawn, namely, the creation of a monopoly in certain hospital appointments by insisting upon the candidate holding some particular qualification. This condition is usually adopted by the governing bodies of the medical charities at the suggestion of members of the medical staff. It is understandable that men with high-standard qualifications should seek to exclude men who have gained their laurels in Ireland or Scotland. But that which is natural may be at the same time absolutely unjust. The London men, in one supposed instance, attempt to exclude competition by establishing an arbitrary tariff condition, so to speak. In other words, they are attempting to establish a monopoly in valuable hospital appointments by way of "protection." In various ways the public and the medical profession suffer from the extinction of competition at which they aim. All qualifying bodies outside London, for instance, are placed at an immediate disadvantage, inasmuch as their graduates as diplomas are seriously handicapped in the struggle of professional life by finding the road blocked to many honourable posts. Nor is there any guarantee that better men are provided by any one examining body, however high the standard imposed. Indeed, so far as that goes, at the present moment a prolonged wrangle is still being conducted by the General Medical Council with two London Colleges who refuse to bring part of their curriculum to a satisfactory standard. Yet these very colleges are the most energetic in demanding a monopoly for their diplomats. Only a few days since, the amalgamation of two orthopaedic hospitals in London was made the occasion of an amendment by the staff of one of the institutions that none but Fellows of the London College of Surgeons could be permitted to hold any post in the amalgamated hospital.

This attitude on the part of a small special hospital will be regarded by many thinking persons as offensive, arrogant and contrary to the interests of the public, of the hospital concerned, and of the medical profession. It is a direct slight to every one of the multitude of medical men in the Metropolis who do not hold the degree of that particular College, not to mention those in the rest of the United Kingdom. We have no hesitation in saying that the "protection" of particular qualifications in the matter of hospital posts is not only contrary to the democratic spirit of the age, but that it is false to the generous spirit that should guide the internal policy of a great and humane profession. Like all other attempts to advance class interests at the expense of justice, it must sooner or later end in disaster. Were the provinces to adopt a retaliatory position, and exclude any but provincial qualifications, the greater loss would be at once shifted to the shoulders of the London men. Yet who could blame the provinces for making so obvious and simple a retort?

INEBRIETY AND MATERNITY.

Among the many public evils of modern life demanding the attention of physicians and legislators alike, few are of such far-reaching importance to the welfare of the race as the growing habit of indulgence in alcoholic liquors by young married women. If the root be corrupt there is little chance of the fruit ever attaining to perfection, and similarly, if the constitution of the unborn babe or the tender nursling be undermined through the intemperance of the mother it can hardly be expected to arrive at complete physical or mental maturity. If inebriety be so widely spread, especially among the working-class population of the great cities, as it is believed to be, another influence is at work which cannot promote anything but degeneration, physical and moral, in the offspring. The practice of giving alcohol to women in child-bed in the shape of gin and brandy appears to be on the increase, and it is not an uncommon thing for a woman who has reformed during her stay in a retreat to relapse entirely into her old ways after the birth of another child. Not content with taking stimulants themselves, these women seek to cure the various minor infantile ailments with drops of spirits, so that their unfortunate children become almost literally "gin-soaked." Can it be wondered, therefore, that, if their lives be spared at all, such infants grow up unstable in mind and body, bearing in them the seeds of the mothers' vice in the shape of some physical or moral malformation or perversion, only to be perpetuated in a more aggravated form through a third generation? The opinion of experts on the subject goes to show that when alcoholism becomes hereditary, the whole family is doomed, neuroses appearing in the second generation, epilepsy and other forms of mental instability in the third, actual imbecility and ultimate extinction in the fourth. Apart from the effects upon the mind, there is the increased predisposition to tuberculosis and certain diseases.
of the nervous system, combined with a steady tendency towards physical deterioration. As to the causes which lead women so to indulge, idleness and grief seem to take the first place, though at the opposite poles of society. The richer classes, or that section of them which has nothing to do, find amusement in giving way to secret drinking, and even frequent private counters of innocent-looking confectioners' shops for the purpose of indulging in alcoholic beverages. At the other extremity of the social scale, it is sometimes little to be wondered at, when one thinks of the misery and want endured by the poor, that a sure, if temporary solace is found in the spirit bottle. They do not intend to wilfully injure their little ones; such a thought probably never crosses their minds; they simply live for the immediate present, and any wrongs inflicted upon their offspring are done in selfishness and ignorance in the vast majority of instances. When the supply of alcohol is prohibited altogether, as in gaol, it is then noted that when a child is born in prison it usually presents a better physique than the remaining members of the family. The whole subject of inebriety among young married women, and indeed in the female sex generally, is one which is difficult to handle, whether from the aspect of the physician or the legislator, and it is more likely that reforms in this direction will be effected by individual advice proffered by tactful and not too obstructive visitors, medical or otherwise, who will take the trouble to go into the homes of the people, than by any systematic legal restrictions. The peril of inebriety in maternity is a real one, and like other dangers which menace the public health must be boldly faced.

Notes on Current Topics.

What is an Accident?

A recent judgment of the House of Lords decides a point of considerable practical importance to the community in general, and also of considerable interest to the medical profession. A man in the discharge of a duty which necessitated the employment of force acquired a hernia, and sued his employer under the Workman's Compensation Act. The defendants contended that the plaintiff had not sustained injuries through an accident within the meaning of the Act, and this view was upheld by the County Court Judge, who was in turn supported by the Court of Appeal. The House of Lords has, however, taken another view; reversed the decision of the inferior Courts, and awarded the man the compensation for which he sought. The point to be decided is a knotty one, and one which, as apparently the Courts found, affords scope for considerable differences of opinion. Whatever may be the legal interpretation of the words of the Act, in our opinion the acquisition of a hernia should not be deemed to be an injury the result of an accident, inasmuch as to permit of its occurrence there must have been some previous pathological condition. A healthy man, in whom the various possible hernial tracks are properly closed, cannot to our mind acquire a hernia from some slight exertion. If he can, who would be found who did not possess one? Suppose a man ruptures a gastric ulcer whilst discharging his duty, is that an accident within the meaning of the Act? If it is, where is the definition of an accident to stop? If it is not, why should a distinction be made in the case of the rupture of some already overstretched band of fascial fibre that permits an intestine to leave the peritoneal cavity. Reasoning by analogy is notoriously unreliable, but it cannot for that reason be altogether neglected. To our mind injuries should only be considered as the direct result of an accident, for the purposes of the Act, when they occur independently of any previous pathological condition. The Workman's Compensation Act is altogether a curious anomaly. In the first instance it inaugurated the absurd system of compensating a man for the consequences or risks he voluntarily undertook, and for the result of carelessness. It now undertakes to further compensate him for injuries the result of previous bodily deformities or ill health. Such Acts will eventually injure the class they are intended to benefit. We are informed that in many parts of Great Britain at present, the moment a workman shows signs of ill health or advancing age he is dismissed, and replaced by a younger man, not because he is unable to do his work, but for fear of the consequences of the Workman's Compensation Act.

The Future of the Army Medical Service.

The Secretary of State for War paid a well-deserved compliment to the civilian members of the Advisory Board of the Army Medical Department, during the discussion on the vote for "Medical Establishment." As he himself bore willing testimony, he has been particularly fortunate in the assistance he has received from the medical profession, in the work of reorganising the Service. He invited some of the most eminent members of the profession to assist him in this work and he "could not now sufficiently express his indebtedness to those gentlemen who had given up high fees and personal practice to sit with him on a committee, and who, having done that, had expressed themselves willing to serve on the Advisory Board at a nominal honorarium." The Secretary for War has indeed good reason to congratulate himself. The Committee which was appointed in the first instance had to deal with a service which was undemanned, discredited, and condemned by every medical body in the country. The Advisory Board when it was appointed had to set itself to reconstitute this service, and so well has it done so, that, whereas at the time it was appointed sufficient candidates could not be obtained to fill the vacancies, at the last examination seventy-two candidates applied for thirty vacancies. The reorganised service has made an excellent start and one which we trust will be followed by a no less excellent career. There are still perhaps a few minor matters which militate against its complete success, but these will, we feel
sure be removed as time goes on. One may perhaps be mentioned. The examinations are said not to be conducted with that strict impartiality which alone is fair, and not alone fair but necessary. It is hinted that examiners favour candidates who come from their own schools, and are inclined, perhaps, to discredit those who do not. Every examiner knows how hard it is to avoid unintentionally favouring a candidate who is well versed in the particular foibles of the examiner, and what a constant strain it is to avoid doing so. When, therefore, by overt acts or words an examiner shows that he intentionally favours or decries a candidate, it becomes a matter of serious importance. We are loth to believe that the preferences shown by examiners in this case are other than involuntary, but for the good of the service it is necessary that no trace of real or supposed unfairness should appear.

The Army and Civilian Medical Assistance.
A royal warrant which was issued at the commencement of the present month will be of interest to many medical men, as it may in the future directly affect them. The warrant provides that " when a detachment of the Army is not within reach of a military medical man, the officer commanding may call in a civilian medical man to render medical attendance to the officers and men belonging to the detachment, and to other persons entitled thereto at the public expense, at the undermentioned yearly rates (which include the cost of medicine) —If there are less than 10 persons £5; if there are 10 persons or more, for every complete 25, or a portion of 25, provided that the total emoluments for all services, exclusive of the examination of recruits, shall not in any instance exceed £10, for any one day. Under special circumstances, and when the medical duties required of the civilian practitioner do not come within the range of ordinary medical attendance, the remuneration shall be at such rates as may be determined by the commander of the army corps, or the officer commanding a district lying outside an army corps command." We consider that it would be more to the interests of military patients if medicines were provided from a source independent of the medical officer. There are many objections to the grouping together of advice and medicine, and we regret that the War Office perpetuates such a system.

A Superstitious Custom.
Our medical and lay contemporaries are exercising their ingenuity to account for the superstitious custom that is being practised in Cambridgeshire of bringing a goat into and around houses in which any person is ill. We find it gravely stated that the emanation of caprylic acid from the animal body has an antiseptic property. Our lay contemporaries incline to the view that goats are lucky. The explanation is withal simple: it is the perpetuation of the old Jewish ceremonial, shorn of course, of almost all its rites and formalities, of selecting a scape-goat. " The goat, on which the lot fell to be a scape-goat, shall be presented alive before the Lord, to make an atonement with him, and to let him go for a scape-goat, into the wilderness." This view finds confirmation in the form of exorcism in the first Prayer-book of King Edward VI., the exorcisms of the Sarum Missal and other such books. The ceremony survives, as Spencer says, long after the occasion that called for its observance has passed away, and it lingers on from age to age to become endowed with mythical virtues and practised with superstitious reverence.

The Society of Apothecaries, London.
This letter published in a contemporary from Mr. Upton, clerk of the Society of Apothecaries, in order to correct the impression that might have arisen regarding the relations between the Medical Council and the Society, deserves attention. It seems well that the competition among the various examining and licensing bodies should, if possible, be corrected and controlled by the Medical Council, particularly if the facilities of passing examinations be held out as an inducement to students to prefer some examining bodies to others. At one time there was a distinct difference between the licenses granted by the Royal Colleges of Physicians and Surgeons, and by the Society of Apothecaries, and the rivalry between them did not exist as at present. It is not very clear in what respect the license of the Conjoint Board is superior to, or more useful to, general practitioners than that of the Apothecaries' Society; and if what Mr. Upton says may be taken as evidence of the character of the examinations, it certainly appears that "The Hall" is keeping up a higher standard in some important respects than the Conjoint Board. In the practice of the law the line is clearly drawn between barrister and solicitor, and there is no such competition among the licensing bodies as in the medical profession. As the L.S.A. is a full license, and the Army and Navy admit those holding it to their Services, the question becomes an important one for those who intend following general practice, whether the L.S.A. is not as useful as the L.R.C.P., M.R.C.S. That kind of practical knowledge which is really of great importance to those who are going to our Colonies or have to settle in country practice, is somewhat neglected by the Conjoint examiners. At "The Hall," on the other hand, more attention is paid to the practical side. We would express a hope that the discord which has arisen between the Medical Council and the Conjoint Board, and which Mr. Upton points out was not participated in by the Society of Apothecaries, may be settled soon to the credit of all concerned.

Irish Medical Honours.
We desire to offer our warmest congratulations to the Royal Colleges of Physicians and Surgeons of Ireland, on the honour which his Majesty has conferred upon them in the person of their respective Presidents. Sir Arthur Macan, President of the Royal College of Physicians, well deserves the honour which has been bestowed upon him. He is best known as a former distinguished Master
of the Rotunda Hospital, and as King’s Professor of Midwifery in the School of Physic, Trinity College. To him are due to a wide extent the present high standard of Irish gynaecology and obstetrics. He was largely, if not entirely, responsible for the first introduction of the knowledge and practice of antisepsis into Dublin, and for the foundation of rational gynaecology. He is an Ex-President of the British Gynaecological Society, and was honorary President of the Obstetrical Section of the International Medical Congress of Berlin in 1886. Sir Lambert was the President of the Royal College of Surgeons, is a distinguished member of the Staff of the Meath Hospital, where he has done much good work. In addition to his medical duties he has taken a deep interest in the condition of the poor of Dublin, and has worked to improve the conditions under which they live with considerable success. He has also interested himself largely in the present, and, indeed, in all past movements, for the reform of the Irish Poor Law Medical Service. The honour which his Majesty has bestowed on the Irish Colleges, and through them on Medicine in Ireland, will be approved by the medical profession throughout the country.

Diachylon as an Abortive.

The power of the various salts of lead to produce expulsion of the ovum is well known, a fact which is further exemplified by the comparative frequency with which abortion is seen among women-workers in some of the pottery districts when affected with plumbism, to which they are peculiarly liable. The internal administration of lead for the purpose of intentionally procuring abortion is of sufficiently rare occurrence and demands no more than a passing notice. At the recent County Assizes held at Stafford before Mr. Justice Ridley, two married women, Elizabeth Maria Goodall, aged 45, and her mother, Sophia Emily Mellor, aged 67, were indicted for supplying certain quantities of a noxious drug with intent to produce miscarriage, and the former was also charged with the manslaughter of Annie Cheadle by the same means. Evidence was given of the purchase of pills from the accused by several married women, all of whom were taken seriously ill with symptoms of irritable poisoning, and one of them, Annie Cheadle, had died. The pills contained diachylon and jalap. In the case of Goodall, the defence was that the deceased woman died of chronic renal disease, and not of lead-poisoning. This may have been the case, but it is notorious that chronic nephritis, if not actually produced by the toxic action of lead upon the system, may at least be aggravated thereby. However, as it is difficult or impossible to distinguish between the nephritis produced by lead and the condition of ordinary granular kidney, this charge broke down and a conviction was obtained for the former indictment only. Considering the gravity of the offence in both cases the sentences of seven years’ penal servitude for Goodall and four for Mellor do not appear to be any too severe. It is only by the example of punishing such offenders that the plague of abortion-mongers can be stamped out from our midst.

The Natural Cure of Deformities.

The effect of time in modifying natural processes is familiar to all. Unrelentless and inexorable, it produces changes which human agency may postpone but is powerless to prevent. On the other hand, it is the great healer, and as such is welcomed by all the disciples of Asclepius who, in a sense, are truly “time-servers.” Time is necessary for all growth, and growth may be sometimes very effective in helping the surgeon to overcome certain physical defects, especially of the osseous system. As an agent in the removal of deformities the value of growth was insisted upon by Mr. Howard Marsh in the Cavendish Lecture of 1888. It is in the various rickety deformities that these beneficial effects are, perhaps, best seen. The buttress in the concavity of the shaft of a rickety bone or in one with a green-stick fracture; the lengthening out of the scoliotic spine in favourable circumstances and the cure of the displacement of the tibia in tuberculous disease of the knee-joint as a result of the judicious application of immobilising apparatus are all familiar examples of the manner in which Nature comes to the assistance of art. More recently, Dr. Judson has pointed out before the New York Academy of Medicine that advantage may sometimes be taken of this principle in the treatment of congenital talipes equino-varus, and he has prepared charts showing how the increase in size of the infant’s foot by natural growth tends towards the ultimate disappearance of the deformity. Desirable though non-operative measures may be under certain conditions, yet it is obvious that cases in which there is no need for prompt action on the part of the surgeon must be few and far between. Though Nature may be slow and sure, the necessities of existence demand that the cure of deformities should be attempted and effected in as short a time as possible. Club-foot is one of these, for upon its successful treatment may depend the wage-earning ability of the patient in the future.

Therapeutics “In Extremis.”

The limitations of the healing art and the helplessness of the physician are only too painfully manifest when the silver cord is about to be loosed and when the wheel of life shall revolve for the last time. Amid the many conflicting impulses of the moment and the natural emotions which all feel more or less, and some more than others, the central fact remains prominent and should ever be kept uppermost—namely, that it is the physician’s bounden duty to fan the flickering flame of life to the utmost of his ability. The policy of laisser-faire should never be countenanced, for it is fatal to the spirit of true scientific therapeutics. Though he fail in his noble endeavours ninety-nine times, in the hundredth he may be rewarded. M. F. Léjars, of Paris, classifies the various moribund conditions into those produced by severe injury, by anemic states, and by toxic agents. When suddenly confronted with emergencies of
this nature the medical man’s first aim should be to support the heart. The diffusible stimulants such as strychnine, ether, and alcohol, combined with direct cardiac tonics such as caffeine or digitalis, will most probably be called for. Stress is also laid upon the great value of serotherapy as a means of helping the heart. Hypodermic and intra-venous injections, or, if there be no time for the necessary preparations, the injection of a large quantity of hot saline solution per rectum, are indicated, and it is often astonishing to see how patients who are literally in extremis will revive when these means have been adopted. In the first class of cases, it is the bold incision, the prompt amputation, the free drainage, which may save life even when it appears altogether impossible.

The Port of London.

The vigilance with which the sanitary authorities guard the port of the great Metropolis is a matter for great satisfaction, and Londoners should have every reason to be proud of the well-developed condition of the “health conscience” of the Port Sanitary Committee. At a recent conference with the Main Drainage Committee the question of the disposal of sewage was discussed. It appears that the Thames Estuary is still in danger of contamination by the discharge of sewage from certain towns situated upon its banks. The possibility of more or less serious injury to the fishing industry is one which must be borne in mind in this connection. The removal of the sludge ten miles further seaward would obviate this risk, but this would mean the increase in the fleet of the sludge-carrying steamers and considerable additional expense. It remains to be seen whether the danger is sufficiently great to necessitate such a step or whether some other means of purifying the water could be utilised. One interesting fact was stated—namely, that 228,116 rats had been destroyed since January 1st. These animal pests have been repeatedly proved to be sources of infection and disseminators of disease, especially of plague, so that the destruction of so many is a great hygienic achievement. The work of the various medical and other inspectors connected with the Port of London is most responsible, and it is very gratifying to note how keenly the officials, one and all, regard the importance of their duties and the welfare of the City.

Quack nostrums and the Medicine Stamp Act.

It is reported that drastic restrictions have been placed on the advertising of quack, alias proprietary, nostrums in Prussia, and the manufacturers of such articles are naturally much perturbed thereat. Mendacious advertisement is, to these people, as the very breath of their nostrils, and if that easy means of deceiving the public be withdrawn the sale of their products must in great measure cease. British and American manufacturers will suffer severely, a foreign-made article appealing with special force to a certain class of the communities. Moreover, the sale of nostrums containing even minute quantities of poisonous drugs is absolutely forbidden except on a medical prescription. Even in this country, where unscrupulous advertisers of secret preparations are allowed a free hand to prey on the ignorant and the sick, the business threatens to become a less easy matter. We do not envy the task of the Somerset House authorities who are called upon every day of their lives to decide whether this or that label renders the product liable to duty. These authorities are notoriously not of one mind, and what one official accords another may deny, nay, the self-same official changes his own mind at tolerably frequent intervals, and curses where erstwhile he blessed. The last departure—one, too, which bears the mark of sterling common sense—is to insist upon all pills and products bearing descriptive names paying the tax. It follows that the host of antibilious pills, liver pills and the like, many of them sold at a penny the box, will have to contribute to the revenue. It is open to the vendors to print the nature of the components on the label, and thus escape the tax, but this would give the whole thing away without achieving the object in view, which is to convince the public that they are buying panaceas for their ailments, all and sundry.

Mr. Edison and the X-Rays.

In the present uncertain state of our knowledge of the X- and various “rays” it would not be safe to deny any statement, however intrinsically improbable; but Mr. Edison’s recent indictment of the Röntgen rays invites us to admit possibilities hitherto not only unknown, but unsuspected. To specially powerful rays of this kind he attributes, for instance, a disturbed digestion, a complaint but too familiar to hosts of Americans who would not know an X-ray from a caterpillar. Moreover he states that “lumps have formed all over his stomach,” a phenomenon which suggests a positively alarming diagnosis. It may be, as has been suggested, that the rays so irritate the militant phagocytes as to provoke them to wreck the organism of which they constitute the garrison, but the indictment must be more closely formulated before we can render a verdict of manslaughter with premeditation against the active cell, whose defensive work Professor Metchnikoff has so eloquently described. We would remind Mr. Edison that the post hoc must not be confused with the propter hoc, and an exact diagnosis might conceivably be arrived at if he were examined by a special committee appointed by one or more of the local medical societies.

The Death of Phil May.

The untimely death of the celebrated caricaturist at an age when he might reasonably have been expected to exercise the plenitude of his powers will leave a blank, greater possibly than that which would have been created by the disappearance of several distinguished lawyers and physicians. Phil May was essentially a
humorist, and his pleasantry was invariably characterised by quaint good-humour without even a suspicion of spitefulness. He did not often draw his subjects from medical practice, but when he did so he steered wide of any appearance of criticism à la Molière. He was genial but eccentric in his bearing, and his life history tends to reinforce the dictum that genius approaches the borderland of the mentally unstable, an instability which was reflected in his mode of life. It is a maxim in psychology that an unusually acute sense of the ludicrous is indicative of a certain lack of mental equilibrium, and the exuberance of this faculty, or sense, in Phil May may explain in part his premature decay. Even in his last moments he displayed the same keen appreciation of the comical and the whimsical, but we have not the heart to tear aside the veil from the bedside of the dying genius.

The Birth-Rate in Fiction.
An old proverb declares that it is man's duty to plant trees and beget children. The latter has for some time shown signs of decay. Child-bearing is becoming unpopular, and the responsibilities of parenthood are willingly shirked. Not only in actual life is this the case, but the same tendency is manifest in modern fiction, and the drama of to-day deals little with large families. It is interesting to compare the pictures of domestic life as portrayed in the novels of a bygone day with the delineations of home as seen in current fiction. We fear present-day literature is all too true an indication of the spirit which is making for a progressively falling birth-rate, with its serious consequences on racial progress. The decrease in the size of families is a subject not only of wide sociological interest, but one which has important bearings on various morbid conditions which face the physician of to-day and call for the most careful study.

Holiday Horrors.
The holiday brings disaster to many. A vacation is often an opportunity for the establishment of processes which undermine vitality. The recess, instead of bringing recreation, not infrequently becomes the dating point from which lifelong suffering may be reckoned. The exodus from town and city to mountain, moor and sea means to many a blind plunge into reckless indulgence and ignorant procedure, which makes for decadence rather than recuperation, degeneration instead of upbuilding. No one can seriously study the impulse of a holiday crowd, or watch the wayward wanderings of the average excursionist without being appalled at the profound ignorance manifested as to the need for attention to the most elementary principles of hygienic life. In days when work seems principally to consist in a preparation for holidays, and when duties seem to be undertaken merely as a means to vacation delights, it would surely be well if those, who in schools or institutions where instruction is supposed to be given, could arrange for an exposition of the hygiene of holidays. The marring of mankind by the abuse of what should be instrumental in its evolution to higher planes offers a melancholy spectacle, which the medical mind would fain see altered.

Municipal Medicines.
The municipalisation of mankind proceeds apace. It is apparently a necessary part of the movement making for the evolution of the human. We do not pretend to know how far distant the day may be when every physician and each surgeon will rank as a civil servant, an officer of the State. But already medicine is being municipalised. It is no uncommon thing to find notices in public places stating that suitable medicine for the treatment of summer diarrhoea may be obtained free on application at the nearest police station. As far as we can gather, these preparations are given without medical supervision and merely as the result of self-diagnosis. We do not pretend to think that the poor can be induced to seek a legally qualified man's assistance for many of the transitory ailments which so often afflict; but where hospitals abound and medical assistance is forthcoming for the asking, we think it most undesirable that responsible bodies should encourage measures likely to develop irregular practices. It would be well if municipal councils always sought the advice of their medical officers of health in all matters in which the health of the people was directly concerned.

The Increase of Insanity.
The annual report issued by the Commissioners in Lunacy shows a larger increase in the number of the insane during last year than in any previous year—the difference for that year being 3,251. It is a disquieting fact that, although we are able to stem somewhat the tide of certain infectious diseases and prevent many others by enforcing the observance of hygienic laws, our inability to check the development of mental disorders appears to grow in proportion. The increase in 1902 seems to be practically confined to the pauper classes, which is significant when considered along with the physical deterioration which we have seen to be at work among them. The propagation of the physically unfit cannot fail to tell in the long run upon the mental quality and character of their progeny. It is astonishing, at first sight, that the worry and strain of modern life and the struggle for existence do not appear to be responsible for so many cases of insanity as might be expected, but when the chief cause, at any rate among men, is stated to be intemperance, the reason becomes clear. The worry is in all probability there just the same, but its effects are prevented from leaving their mark upon the mind by indulgence in alcoholic liquor which is quite as potent an exciting factor, though a much more pleasant one. The increase is not confined to the Metropolis, but is felt throughout the provinces as well. The cities of Hereford and Exeter have actually a higher percentage than London. The protest of the Commissioners that lunatics should be subjected to examination in their own homes
and not at police-courts is most important, and one which it is to be hoped may be taken to heart by judicial authorities. The more widely the idea is accepted that insanity is a disease and not a crime the more perfect will be the methods for its detection, prevention and treatment.

**Yachting and Health.**

Cowes week is over, and for many fashionable souls the delights of yachting are at an end. It is somewhat remarkable that the hygienic advantages of yachting do not receive wider recognition. Englishmen should not be slow to remember the peculiar benefits which accrue from the geographical situation of their home, and it would be well if facilities could more widely be afforded to the many invalids and convalescents to whom yachting would provide conditions of the highest therapeutic value. We often hear of philanthropic persons presenting a country house for the use of the physically unfaithful, but the owners of yachts, doubtless for very good reasons, are slow to lend their floating homes for purposes of recreation of mind and recuperation of body. Some hospitals have received offers of the loan of motor cars for their patients, but we have never heard of an institution having the opportunity of using a yacht as a convalescent home. And yet, as we have said, a suitably equipped yacht offers peculiar advantages for the restoration of certain cases, and as a prophylactic agent its usefulness might well be made use of.

**PERSONAL.**

**Mr. William Stanford, M.R.C.S.,** has been re-appointed Medical Officer of Health for Tunbridge Wells.

**Dr. T. M. Murray Lyon,** of Mid Calder, has been appointed Justice of the Peace for the county of Midlothian.

**Mr. William Butler, M.B., C.M., D.Ph.,** has been appointed Medical Officer of Health to the Willesden District Council.

**Dr. William Lang,** Government Medical Officer of Grenada, has retired on a pension after forty years service in that colony.

**Mr. F. Sidney Spokes** has been elected a member of the Board of Examiners in Dental Surgery of the Royal College of Surgeons of England.

**Dr. David McCay** has been appointed Assistant Professor of Physiology in the Medical College, Calcutta, and Resident Physician to the Medical College Hospital.

**Dr. D. K. McDowell,** late Principal Medical Officer in Northern Nigeria, is leaving shortly to take up the duties of Principal Civil Medical Officer of the Straits Settlements.

We regret to learn that the son of Dr. Breach, of Yattendon, near Newbury, was killed a few days since as the result of a collision with a butcher’s cart when cycling.

**Dr. S. R. Christopher,** who has had extensive experience of malarial research on the West Coast of Africa, has accepted an engagement to undertake similar work for the Indian Government.

**The late Mrs. Theresa Florence Morgan,** of 36, Walton Street, Pont Street, has left £400 each to the Cancer Hospital at Brompton, the Brompton Consumption Hospital, and the East London Hospital for Children.

**The office of Supernumerary Medical Officer of St. Lucia has been abolished,** and Dr. E. Wells, who has performed the duties for some time past, has been offered the post of Medical Officer of Barrouie, St. Vincent.

**Dr. J. Huglings Jackson** is the recipient of the Moxon Gold Medal, awarded every third year to the physician who should be deemed to have most distinguished himself by observation and research in clinical medicine.

**Dr. Hughes Walsham** has been awarded the Weber Parkes Prize of 150 guineas, and a silver medal, by the Royal College of Physicians, London; a similar medal, distinguished as a second medal, was awarded to Dr. W. J. Horne.

**The Drapers’ Company,** consequent on the announcement made as to the financial stress now existing, have promised to contribute £4,000 to the Tottenham Hospital on the condition that the hospital authorities raise a sum of £3,000.

**Mr. John Astley Bloxam, F.R.C.S.,** of Bourne End, Bucks, whose retirement from the position of senior surgeon to Charing Cross Hospital was recently announced, has been placed on the Commission of the Peace for Buckinghamshire.

**MRS. M. A. Dacombe Scharlieb, M.D., M.S.,** and Miss C. Violet McLaren, M.B., Ch.B., have been elected members of the Council of the Society for the Study of Inebriety, and are the first lady representatives to whom this honour has been extended since the foundation of the Society in 1884.

**Dr. C. Holman,** the treasurer of Epsom College, has been presented by the Council with his portrait to be hung in the Council Chamber of the College in Soho Square in recognition of his efforts to secure the success of the recent festival dinner.

**Dr. Robert Hutchison** has been appointed the Goulstonian Lecturer, Dr. Frederick Taylor the Lumleian Lecturer, Dr. J. F. Payne the Fitz-Patrick Lecturer for 1904, and Dr. E. H. Starling the Croonian Lecturer for 1905, by the Royal College of Physicians, London.

**The Baly Gold Medal,** founded in 1866 by Dr. F. D. Dyster, of Tenby, awarded every alternate year to the person who shall be deemed to have most distinguished himself in the science of physiology, has been awarded to Dr. J. N. Langley, D.Sc., F.R.S., by the Royal College of Physicians of London.

**Deputy Surgeon-General C. B. Mosse, C.B., C.M.G.,** Superintending Medical Officer of Jamaica, has arrived in England on leave of absence. Prior to proceeding to Jamaica, Dr. Mosse served on the West Coast of Africa for twenty years and took part in the Ashanti War of 1873-74, for which he received the Companionship of the Bath, the medal with clasp, and was mentioned in despatches.
THE WORK OF THE SECTIONS.

Professor Thomas Oliver's address on "Miners Diseases" offered one of the most valuable features of the work of the pathological section. It was shown how, in miners' phthisis, dust particles were carried by the wandering cells of the finer bronchi, which were distinctly phagocytic and mobile, through the branched plasma spaces into the lymphatic canals under the skin, and thence by way of the superficial or peri-bronchial vesicles to the bronchial glands. The general opinion seemed to be that pulmonary tuberculosis developing in miners was usually to be considered a secondary condition due to infection of tissues, the powers of resistance of which had been lowered by local irritation and other influences.

In the laryngology and otology section, Sir Felix Semon discussed the selection of operative procedure for malignant disease of the larynx, indicating the relative advantages of the intralaryngeal method, pharytomy, or with or without removal of fragments of cartilage, partial and total extirpation, subhyoid pharyngotomy and palliative tracheotomy.

Considerable interest was aroused in the discussion on the upper respiratory tract as a source of systemic infection introduced by Dr. de Haviland Hall and Dr. John Horne, who brought out that typhoid fever, measles, influenza, whooping cough, septic fever, tuberculosis, syphilis, infective endocarditis, and other infectious diseases, might be introduced by way of the upper respiratory tract.

In the section devoted to tropical diseases that enthusiastic and veteran pathologist and clinician, Mr. Jonathan Hutchinson, ardently propounded his views regarding the etiology of leprosy, holding that an overwhelming body of evidence is opposed to the belief that leprosy spreads by any ordinary mode of contagion; that hereditary transmission is a rare event; that communal communication occurs occasionally, but is by no means frequent; that in all countries where leprosy is not common a great majority of the cases seem to arise spontaneously; that the available evidence points to leprosy being due to fish, that the very excessive prevalence of leprosy in certain fishing districts is a fact strongly in favour of the fish hypothesis, and that its excessive incidence in Roman Catholic communities supports the same conclusion.

We have arranged to publish during the next few weeks abstract papers of the more important communications presented at the Swansea meeting.

MEETINGS OF SOCIETIES.

The members of the would-be-cosmopolitan Continental Anglo-American Society, July 30th, lunched together at the Hotel Métropole, at Swansea, Dr. A. J. Freeman, of San Remo, being in the chair. Although the number of "foreign residents" was not large the gathering was full of pleasant associations, and did much to renew old friendships.

During the annual meeting week the friends and subscribers of the New Sydneyhams Society held their yearly gathering.

The Irish Medical Schools and Graduates Association also held their summer general meeting.

The National Temperance League's Annual Breakfast was a great success, interesting speeches being made by the President, Sir Victor Horne; Professor Monach Cameron, Surgeon-General Evatt, Dr. Rawlings, Mr. McAdam Eccles, and others.

Perhaps the most serious function of the annual meeting is that of the "Dinner." That meeting was this year held in the "Daily Journal" of addresses opening important discussions, and it is to be regretted that in every case an abstract is not published at least a week before the opening of the annual meeting.
THE PATHOLOGICAL MUSEUM.

The pathological museum has for long proved an attractive feature of the annual meeting of the British Medical Association, at least to scientific members. It actually forms one of the most instructive and suggestive departments of the yearly gathering. It affords an opportunity for demonstrating the results of much of the year’s research and supplies means for presenting suggestive evidence regarding morbid conditions still needing investigation and awaiting elucidation. This year’s collection, thanks to the energy and wise discernment of Dr. Daniel E. Evans, of Swansea, and Dr. Newman Neild, of Bristol, proved a rich one. We much regretted to find that but few visitors appeared to devote any serious study to the excellent specimens, although in arrangement and by clear labelling considerable effort had been expended to make each exhibit readily accessible to the observer.

A conveniently-arranged catalogue of forty-seven pages supplied useful descriptions of 218 preparations. Many interesting specimens were shown from the museums at the Bristol General Hospital and the Bristol Royal Children’s Hospital. A preparation of Dr. Mitchell Clarke’s admirably showed an aneurysm of the aorta opening into the inferior vena cava, and Bassett-Smith, of Haslar, exhibited a fine series of preparations of aneurysms. Drs. Poynont and Paine showed specimens of experimental endocarditis and osteo-arthritis. A particularly good example of syphilitic fibrosis of the lung was put into the collection, and there was an interesting specimen of congenital syphilitic child from a child of six. A good series of preparations illustrated the various morbid conditions affecting the spleen. There was an excellent sample of spindle-celled sarcoma from a child, aged one and a half years. Mr. Henry Juler exhibited a valuable collection of ophthalmic lesions.

A large number of radiograms, drawings, photographs and diagrams were exhibited, several of much interest coming from Haslar Naval Hospital. Mr. Alfred Eddowes showed good drawings of veldt sore. Mr. Hutchinson supplied a particularly valuable selection from the museum of the London Post Graduate College and Polyclinic. A collection of mosquitoes, British and foreign, deserved particular attention. Among the microscopic preparations Dr. Mitchell Clarke, of Clifton, exhibited several of much neurological importance.

We are strongly of opinion that it would be well if a serious attempt could be made to ensure that the Annual Pathological Museum provided so far as possible a complete demonstration of the best work in this country in the preceding year, and so afford a practical presentation of collective investigation into such matters as can be exhibited by our ordinary macroscopic and microscopic methods.

Special Correspondence.

(We do not hold ourselves responsible for the opinions of our correspondents.)

[FROM OUR SPECIAL CORRESPONDENT.]

SCOTLAND.

THE HEALTH OF EDINBURGH.—The report by Sir Henry Littlejohn for the year 1902, just published, records a comparatively uneventful, and therefore satisfactorily, period of improvement. The death-rate, deducting "country deaths," i.e., those of persons coming into the city for treatment in medical institutions, was 15.8 per 1,000, the lowest record except in 1890. The infantile death-rate per 1,000 births was 17.4, the lowest ever recorded with 143 and 132 in the two preceding years. The birth-rate was only 24.4, the second lowest of the eight great towns in Scotland, and comparing unfavourably with the general rate in England and Wales of 28.5, and with that of Glasgow of 32.7; 7.5 per cent. of the births were illegitimate. The syphilitic death-rate was 1.08 per 1,000—somewhat below the average. Tuberculosis accounted for 625 deaths, or 2 per 1,000, and cancer for 312. In the year under review, changes were made in the notification of infectious disease, measles being discarded, and erysipelas and puerperal fever included. As a result, notifications fell from 7,053 to 1,968, and, excluding from these notifications, there has been a general diminution of infectious disease, chiefly due to a marked decrease in the amount of diphtheria, which still, however, is much more prevalent than in the years preceding. Mortality from zymotic diseases shows that the diseases are more fatal to patients treated in their own homes than in the Town Hospital. In typhoid, for example, of which only 192 cases were notified, the lowest rate, since 1880, the death-rate in hospital was 2.75 per cent.; of cases treated at home 35 per cent. The case mortality of diphtheria is now only 7.8 per cent., a truly marvellous improvement compared with 14 per cent. in 1898 and 24.7 in 1893. Towards the end of the year 1901 the Council decided to transfer bacteriological work from the College of Physicians’ Laboratory to the Usher Institute. In that year the number of specimens reported was £127 155.; in 1902 only 383 specimens were examined for the annual sum of £500 granted to the Institute. It should, however, be noted that the diminution in the number of specimens examined is not due to any diminution in the exact state of matters, since many medical men prefer to have their reporting work done unofficially by the College laboratory. Under the Factory and Workshop Act the registration and inspection of workshops has been transferred to the medical officer’s department from that of the sanitary inspector, and in many instances improved sanitary appliances have been put in, linewashing carried out, &c. The superintendence of the inspector on the report the proposed removal of the slaughter houses and cattle market from their present central position to the outskirts of the town is favourably reported on. Sir Henry Littlejohn recalling that he urged this course on the town so long ago as 1892.

COMPLETION OF THE EXTENSION OF THE ROYAL INFIRMARY, EDINBURGH.—The occupation of the recently finished new pavilions in the infirmary in a few weeks’ time will mark the completion of the scheme of extension which has been in progress for some years and of which the penultimate stage was reached in the opening of the Diamond Jubilee Pavilion in 1897. In 1898, through the receipt of a legacy of £130,000 from the late Mr. Yule, the managers found themselves able to proceed with the erection of the new ear, nose, and throat pavilions, which were commenced in the spring of 1900. Their long axes run east and west north and south, like those of the rest of the hospital. The ophthalmological pavilion consists of three floors and attic, the laryngological of two floors and attic. In each the basement is given over to an out-patient department, which is completely isolated from the wards above. Both pavilions communicate with the rest of the infirmary by covered ways, so that there is as little interference as may be with light and air. In the eye pavilion each floor contains two ten-bed wards, one for males and one for females, while between the two are operating rooms, surgeons’ rooms, kitchens, &c. The beds are arranged so that the light does not fall into the patients’ eyes, and each ward is sub-divided by a screen in order that the light may be graduated for different classes of patients. In the ear and throat pavilion the first floor has ten-bed wards, with the necessary operating rooms, kitchens, &c. The buildings are fireproof, and the walls non-absorbent. The architects are Messrs. Sydney Mitchell and Wilson. The whole extension will cost about £130,000, including site, and though the balance in hand falls short of what is needed to meet outstanding accounts by about £6,000, it is a most striking fact that the opportune receipt of large donations and legacies enabled the managers to carry out this substantial increase without appealing to the general public.
CORRESPONDENCE.

AUG 12, 1903.

MENINGITIS IN CHILDREN.

To the Editor of The Medical Press and Circular.

Sir,—You will perhaps allow me to reply to Dr. Lee's letter in the current issue. At the outset, let me state that the two cases of meningitis which I described in a short paper were almost beyond a doubt tuberculosis in their character. In the first case the child's mother suffered from advanced pulmonary tuberculosis, while several of her maternal uncles and aunts had died of the latter disease. The second case was one in which I maintain that the meningial condition was secondary to what in all probability was an early tuberculous lesion of the lung apex; and this contention is borne out by the fact that the girl's father died of pulmonary tuberculosis. Of course, there is nothing absolutely certain in Nature, but I think we must take facts as we find them, and deduce inferences from these. Without a post-mortem examination I quite admit that the practitioner may be led astray into drawing erroneous conclusions as to the nature of many of his fatal cases. I have, indeed, seen this happen many times, both in the case of hospital and of private physicians. I do not, however, see that my diagnosis of the two particular cases of meningitis which were recently published in your journal can be called in question in the face of the facts which I have stated.

Dr. Lee makes so much I should like to express my entire approval of the view which Dr. Lee maintains with reference to many of the cases of so-called tuberculous meningitis. We often find cases reported as cured, and I am at one with those who regard these as simple (septic, if you will) and not tuberculous. I also think that the ordinary text-book descriptions of this disease are far from accurate and complete. Statements made by one authority are apt to be passed on and taken for granted. The whole subject requires the most careful sifting, and a careful record of cases both from a clinical and pathological standpoint would help greatly to clear up many misapprehensions regarding this subtle and most intractable disease.

As I am at present on holiday, I have no means of referring to Dr. Lee's original paper on the subject; but meantime I am indebted to him for his criticism, as it is only thus that we can ever hope to reach the truth.

I am, Sir, yours truly,

JAMES BURNET.

Prestwich, August 8th, 1903.

LITERARY NOTICES AND Gossip.

Dr. George S. Keith's "Plea for a Simpler Life" has been issued by Messrs. Black in a popular sixpenny edition.

President David S. Jordan contributes an interesting paper on "The Training of a Physician" to the August number of the American Popular Science monthly.

Messrs. Macmillan and Company have just issued a delightful work on "Norwegian By-Ways," by Mr. Charles W. Wood, which should prove invaluable to health seekers in the land of the Northern lights.

Dr. T. J. T. Tonkin, the Medical Officer of the Hausa Association's Central Soudan Expedition, in the current issue of the Empire Review commences a valuable study of the lepers of Northern Nigeria.

Sir James Crichton-Browne's new Carlyle volume, "The Nemesis of Froude," is expected to be published about the middle of September, and no doubt will add fresh fuel to the now fortunately slumbering fire.

Visitors to Switzerland will do well to provide themselves with Mr. John Murray's new editions of "The Peculiarly Attractive Guides to the Range of Mont Blanc" and "The Valley of Zermatt and the Matterhorn," both volumes being by Mr. Edward Whymper.

We are sorry to find that the publication of Vectis is to cease. This dainty and peculiarly attractive journal, rich in literary flavour and dramatic interest, has been edited with much spirit by Dr. G. H. R. Davies, the physician of the late Lord Holford, laureate, and the author of a number of brilliant stories.

The Manchester Medical Guild Quarterly for July contains an excellent portrait of the late Prof. Daniel J. Leech, together with a peculiarly sympathetic and delicately-worded biographical sketch. Many of Dr. Leech's old students, now scattered all over the globe, will be interested in reading this appreciation of their old chief.

Holiday seekers who are scampering away to mid-Europe would be well advised to take with them a copy of Dr. Joseph Parisch's new work, "The Regions of the World," issued in "The Regions of the World" Series, edited by Mr. H. J. Mackinden, and published by Mr. William Heinemann. The chapter on the Alps and the German Danube will prove peculiarly attractive to many making for "the playground of Europe.

It is not generally known that "Maxwell Gray" is a lady, Miss Mary Gleed Tuttiett, whose associations with medicine have been very close. Her father, Dr. Tuttiett, practised for many years in Newport, Isle of Wight, and was well known throughout the charming little island. In "The Silence of Dean Maildred" and certain other Miss Tuttiett's justly popular and most delightful novels the scenes are laid in the Isle of Wight.

Falmouth has for long been a favourite resort for those seeking a climate genial to old age and kindly to the invalid. To such as know or wish to see this western resort we commend the charming new work of Miss Susan E. Gay on "Old Falmouth," containing the history of the town from the days of the Killigrew to the earliest part of the nineteenth century. Sir Joseph Fayrer contributes an introduction. The work is charmingly illustrated, and is published by Headley Brothers, of Bishopsgate Street, London.

Mr. J. Holt Schooling, in the current issue of the Fortnightly Review, in an interesting statistical study of cancer as met with in England and Wales during the last forty years, shows that side by side with a continuous decrease in the death-rate from all causes, there has been a continuous increase in the death-rate from cancer, and the increase in the male death-rate from cancer has been much larger than the corresponding female increase, although throughout twenty years the actual female death-rate from cancer has been much higher than the male death-rate.

The "English Handbook to the Paris Medical School," by Dr. A. A. Warden, Visiting Physician to the Hartford British Hospital in Paris, fulfils a long-felt want. Generations of students and practitioners visiting Paris must have felt the need of such a guide, since it affords information which can only be obtained with considerable difficulty from other sources. The author gives a brief sketch of the Faculty of Medicine, followed by a list of the principal hospitals, the names of their medical staff, and their visiting hours. There is also a list of the museums and libraries, a note on the Institut, sundry hints as to the practice of medicine in France, and a list of private institutions. It is published by Messrs. Churchil, price 2s. net.
OATMEAL AS A FOOD.

This cereal is deserving of greater recognition and wider employment as a general food than is at present accorded to it. A well-known scientific writer (a) on the economies of foods says that flour may be regarded as the most nutritious of all cereals,” and to substantiate this statement he draws attention to its richness in fat and proteins as compared with other cereals. It is certainly far richer in fat, since it contains on an average about 8 per cent., while wheat and rice show little more than traces. In proteid value it is richer than wheat, maize, barley, and rye, and contains nearly three times the proteid value of rice. Again, in bone-forming materials (phosphates, calcium salts, &c.) it far surpasses all the above-mentioned.

The average composition to which a fair sample of oats (the husk having been removed) should correspond (b) is as follows:—Fat, about 8 per cent.; proteids 13 to 18 per cent.; mineral matter, 2 to 2.5 per cent. It is, of course, essential that the tough fibrous cortex should be as far as possible separated, and this, if present in too large a proportion, would prove irritating to the intestine. In moderate proportions this fibrous matter is an advantage, in that it stimulates intestinally peristalsis. “Flaking” or “rolling” oats is advantageous, because this process aids in the disintegration and subsequent digestion of the grain. If a fine flour be produced from oats, it will be found that this is richer in starch, and, consequently, poorer in other constituents than the whole grain suitably “rolled” or flaked, and, consequently, the latter forms are preferred. On account of the low percentage of gluten in oats, they cannot be made into bread without the addition of wheaten flour, but in the form of oat-cake or porridge they provide a highly nourishing and valuable form of food, which might be used with great advantage, particularly in the case of children, where it is of great importance to secure an adequate supply of bone-building material, in the absence of which normal development is likely to be hindered.

ALLSOPP’S LAGER BEER.

We have now analytically examined various samples of Allsopp’s Lager Beer, which we have no hesitation in describing as a light alcoholic beverage, pleasantly flavoured, and manufactured from sound materials. Owing to the absence of preservatives, it is free from the mawkish taste which characterises many imported lager beers, and it may therefore safely be assumed to be free from the undesirable physiological effects which are associated with the habitual ingestion of chemical antiseptics. It is an ideal beverage for the warm season, containing as it does only 4.5 per cent. of absolute alcohol per volume. Analysis gives 4.8 grains of extractive per hundred cubic centimetres of beer, or 0.25 per cent. of alcohol. These results are in accordance with the recognised composition of a well-brewed lager beer. It has a delicate flavour of hops, and the product is one which testifies to skilful brewing, so that it can with advantage be recommended as a summer beverage and as a light, mildly stimulating drink with meals.

FATAL ACCIDENT.

Dr. Greenaway, of Tunbridge Wells, accidentally fell off the platform at the South-Eastern Station at that town on Saturday, and was crushed by the foot-boards.” (c) Oats, “Food and Dietetics,”

(b) “Standards for Foods and Drugs,” C. G. Moor, M.D.

JOHN TATHAM, F.R.C.P.

Dr. John Tatham, of Lowfields, Barton-in-Loundale, Lancashire, died on the 3rd inst. of a long-lingering illness, in his sixty-ninth year. After a very successful student’s career at the Middlesex Hospital, where he carried off many prizes, he was appointed house surgeon. He subsequently studied medicine in Paris, and was resident physician to the late Lord Holland. He was M.D. St. Andrews, and later in life was elected a Fellow of the R.C.P. of London. He was for several years physician and subsequently consulting physician, to the Bromption Hospital, and was a regular attendant of the meeting of the hospital, where he did much useful work. Dr. Tatham contributed on hygiene and climate to medical and other journals and hospital reports.

The death took place on the 1st inst., at the age of seventy-nine, of James Weaver, R.N., of Southport, who was surgeon with the British Fleet in the Crimean War and served in the Baltic. He had been in practice at Longton, Staffordshire, for upwards of twenty years, and was the author of several works on medicine.

The death was announced at the age of fifty-three, of Professor Nocard, the distinguished French veterinary surgeon and bacteriologist. He was a member of the French Academy of Medicine, and one of Pasteur’s most distinguished pupils and collaborators. He made a special study of the veterinary branch of the medical profession, on which he wrote many valuable treatises, more particularly, in connection with the pathology and bacteriology of glands.

LABORATORY NOTES.

OATMEAL AS A FOOD.

This cereal is deserving of greater recognition and wider employment as a general food than is at present accorded to it. A well-known scientific writer (a) on the economies of foods says that flour may be regarded as the most nutritious of all cereals,” and to substantiate this statement he draws attention to its richness in fat and proteins as compared with other cereals. It is certainly far richer in fat, since it contains on an average about 8 per cent., while wheat and rice show little more than traces. In proteid value it is richer than wheat, maize, barley, and rye, and contains nearly three times the proteid value of rice. Again, in bone-forming materials (phosphates, calcium salts, &c.) it far surpasses all the above-mentioned.

The average composition to which a fair sample of oats (the husk having been removed) should correspond (b) is as follows:—Fat, about 8 per cent.; proteids 13 to 18 per cent.; mineral matter, 2 to 2.5 per cent. It is, of course, essential that the tough fibrous cortex should be as far as possible separated, and this, if present in too large a proportion, would prove irritating to the intestine. In moderate proportions this fibrous matter is an advantage, in that it stimulates intestinally peristalsis. “Flaking” or “rolling” oats is advantageous, because this process aids in the disintegration and subsequent digestion of the grain. If a fine flour be produced from oats, it will be found that this is richer in starch, and, consequently, poorer in other constituents than the whole grain suitably “rolled” or flaked, and, consequently, the latter forms are preferred. On account of the low percentage of gluten in oats, they cannot be made into bread without the addition of wheaten flour, but in the form of oat-cake or porridge they provide a highly nourishing and valuable form of food, which might be used with great advantage, particularly in the case of children, where it is of great importance to secure an adequate supply of bone-building material, in the absence of which normal development is likely to be hindered.

ALLSOPP’S LAGER BEER.

We have now analytically examined various samples of Allsopp’s Lager Beer, which we have no hesitation in describing as a light alcoholic beverage, pleasantly flavoured, and manufactured from sound materials. Owing to the absence of preservatives, it is free from the mawkish taste which characterises many imported lager beers, and it may therefore safely be assumed to be free from the undesirable physiological effects which are associated with the habitual ingestion of chemical antiseptics. It is an ideal beverage for the warm season, containing as it does only 4.5 per cent. of absolute alcohol per volume. Analysis gives 4.8 grains of extractive per hundred cubic centimetres of beer, or 0.25 per cent. of alcohol. These results are in accordance with the recognised composition of a well-brewed lager beer. It has a delicate flavour of hops, and the product is one which testifies to skilful brewing, so that it can with advantage be recommended as a summer beverage and as a light, mildly stimulating drink with meals.

FATAL ACCIDENT.

The Association of Physicians and Surgeons of the Society of Apothecaries, Limited.

We have been asked to give insertion to the following: "The London Section of this Association has been formed to bind together the Licentiates of the Society of Apothecaries of London, and of the Apothecaries' Hall of Dublin, in order that combined action may be taken, when necessary, to maintain their rights and privileges as fully qualified physicians and surgeons, and to remove the disadvantage under which they at present suffer as to title. It is felt that before long an amendment of the Medical Acts will be sought by the General Medical Council, and as an alteration in title can only be lawfully made by Parliament, it is highly important that there should exist an organised body of Licentiates ready to urge their just claim to modern titles as substitutes for the archaic, though honourable, ones of L.S.A. and I.A.H. There is reason to believe that neither the London Society nor the Dublin Hall will, of their own initiative, take any steps in this matter; but both Corporations would, doubtless, respond to the wishes of their Licentiates, if placed before them by a truly representative body. In order that this Association may become truly representative, and be able to express authoritatively the desires of the Licentiates, it is necessary that it should comprise in its membership a majority of the practitioners who hold the diplomas of L.S.A. and I.A.H. Otherwise there is danger that the association may be regarded as a small band of agitators, and not be able to exercise a proper influence. Since the formation of the Joint Board, the diplomas granted by the Apothecaries' societies have unquestionably, though undeservedly, lost some of the prestige which formerly attached to them, notwithstanding that the examinations for them have been extended in scope, and increased in severity, and are quite equal to those of any of the Joint Boards. This loss of prestige is undoubtedly due to the insignificant titles of the diplomas, when compared with those of the Joint Boards. To endeavour to remove this injustice, which has often been commented on in the leading medical journals, is one of the principal objects of this association, and the council confidently hopes that all Licentiates will apply for admission to membership without delay, in order that they may be ready when the proper moment comes, to press effectively their claim to titles expressive of their qualifications as practitioners of medicine, surgery, and midwifery. Membership is restricted to practitioners registered on the diplomas of the Societies of Apothecaries alone, or in conjunction with a Surgical diploma, as above described.

The Coombe Hospital.

The annual meeting of the supporters of the Coombe Hospital shows that this institution has discharged its duties in a most successful manner during the past year, and that it is preparing to meet the increase in the line of patients. During the past year the new buildings for the accommodation of gynaecological cases have been completed. The new wing includes two large and well-lighted wards, containing twenty beds before them, and an ethical room, ample lavatory accommodation, and an operating theatre, complete in every respect, besides other necessary apartments, with pay patients' wards and wards for infants. A new electric lift has also been erected. The building and commodious house in Ardse Street, close to the hospital, has been altered to suit the requirements of a nurses' home, and awaits occupation. Sleeping accommodation is provided for twenty-five nurses, the sanitary and lavatory arrangements being ample and complete. The admissions into the wards of the hospital showed an increase of 173, and the general dispensary an increase of 1,270, the low mortality in the hospital being especially noticeable. In the gynaecological wards there was only one death, and in the labour wards three, of which one came in dying. During the period under review Dr. Thomas Hall, M.D., National University, having completed his term of office as Assistant-Master, retired, and on the nomination of the Master, Mr. M. J. Gibson, M.B. Dublin University, was applied to the vacancy thus left. Dr. Stevens, the Master, was warmly congratulated on the success of his work in the hospital.

Smallpox at Cambridge.

The epidemic continues to spread, though more slowly. Up to the end of last week the total number of victims exceeded 130, with eight deaths. The outbreak has incidentally been the means of calling attention to the existence of disgraceful shams in this university city, and the lesson will not be thrown away if the authorities take advantage of the opportunity to do something to mitigate a condition of things that constitutes a standing menace to the health of the borough.

A Missing Surgeon.

A young naval surgeon, Dr. W. A. Illingworth, who has stationed at the Royal Naval Hospital, Chatham, has disappeared under mysterious circumstances. On Tuesday evening he went to the Portsmouth Theatre Royal with some brother officers. After leaving the theatre Mr. Illingworth was driven to Portsmouth, but missed the last steam launch across the harbour to Gosport. On discovering this he told the cabman he should take a wherry across. He walked in the direction of the pontoon, where a boat could have been procured, but after that nothing more was seen of him.

Cheap Pharmacy.

In a case tried last week at the North London Police Court a company of pharmacists, known as Parke's Drug Stores, were fined £5 for having sold as Blaud's pills, pills which were deficient in iron carbonate to the extent of at least sixty per cent. The defence was based principally on the fact that the pills were a proprietary article and therefore exempt from control, but the magistrate admitted the contention that the pills ought to comply with the formula for iron pills of the British Pharmacopoeia, or, at any rate, with the Blaud's pill of the French Codex.

A Case for Further Action.

One Richard Jones Owen, of Glasgow, who sports a plate bearing the designation "Dr. Owen," on his door, was charged last week with having sold laudanum, he not being a qualified pharmacist. He had apparently endeavoured to pass himself off as a registered medical practitioner, but on inquiry at the offices of the General Medical Council it was elicited that he had obtained registration under false pretences, upon the defence whereof his name had been erased. He was fined £5; but the matter must not be allowed to remain there in view of his impudent assumption of a medical status.

PASS LISTS.

Royal College of Physicians in London.

At the quarterly meeting of this College held last week the President, Sir William Church, in the chair, the following Fellows of the College were elected officers:—Censors, Sir Dyce Duckworth, M.D., F. T. Roberts, M.D., D. Ferrier, M.D., and W. L. Ferriere, M.D.; Treasurer, Sir Dyce Duckworth, Emeritus Registrar, Sir H. A. Pitman, M.D.; Registrar, E. Liveing, M.D.; Harveian Librarian, J. F. Payne, M.D.; Assistant Registrar, O. A. Browne, M.D.; Library Committee, G. Bee, M.D., P. H. Alway, M.D.; A. E. Garrod, M.D.; Curators of the Museum, W. H. Dickinson, M.D., H. C. Bastian, M.D., W. Cayley, M.D., and J. Abercrombie, M.D.

The following candidates having passed the required

**Royal College of Surgeons, Edinburgh.**

**Royal Army Medical Corps.**

The list of successful candidates for commissions in the Royal Army Medical Corps, who passed at the recent examination in London is as follows, arranged in order of merit:—A. C. H. Gray, 612 marks; D. P. Watson, 569; T. S. Dudding, 567; C. H. Roberts, 558; F. M. O. Cormannay and J. E. Powell, 566 each; R. H. Macnichol, 554; G. Devers, 546; D. D. Paton, 545; S. L. Pallani, 537; G. H. Bradly, 530; H. H. J. Fawcett, 522; T. J. Wright, 521; G. A. Kemphorn, 520; J. T. McEntire, 518; S. E. D. Lennard, 515; N. D. H. Bostock, 513; J. H. D. Bown, 505; N. E. Dunkerton, J. J. Hanafin, and A. C. Osburn, 497 each; M. C. Wetherell, 494; R. T. Collins, 484; W. M. M’Dowell, 483; F. J. Turner, 482; R. C. Hildred, 476; G. S. Alix, 475; J. B. Richardson and F. M. G. Tulloch, 475 each; E. M. Clannig, 471.

**Indian Medical Service.**

List of candidates for his Majesty’s Indian Medical Service who were successful at the Competitive Examination held in London on August 3rd, 1903, and passing days:—41 candidates, of whom 23 had university degrees, competed for 16 appointments; 29 were reported qualified:—Name. Marks. Name. Marks. R. Reels 3739 E. T. Harris 3159 J. H. Burgess 3546 C. J. Brierley 3521 C. H. Brodbibb 3599 R. F. Steel 3057 J. M. C. A. Macmillan 3448 J. B. D. Hunter 3061 G. A. Gill 3361 A. C. Ingram 3046 G. F. I. Harkness 3253 E. W. C. Bradfield 3024 F. T. Owens 3242 Highest possible number of marks, 5,100.

**The Victoria University.**

The following passed the undergraduate examination during July (names are arranged):—

THE TREATMENT OF ANEURYSM BY SUBCUTANEOUS INJECTION OF GELATINE. (a)

By GUTHRIE RANKIN, M.D., M.R.C.P.,
Physician to the Dreadnought Hospital, Greenwich; Senior Assistant Physician to the Royal Hospital for Children and Women.

Aneurysm is such a desperate disease, and one which so frequently terminates in a tragic and sudden manner, that any treatment which offers a fair chance of success deserves to be seriously considered.

The method of subcutaneous injection of gelatine, first recommended by Lancereaux in 1897, is the latest and most promising medicinal means by which it has been attempted to lessen the dangers and miseries attendant upon aneurysmal dilatation of an artery.

A fuller knowledge of Lancereaux’s means of cure, and of its capabilities for good or evil, can only be achieved by a record of the results attained in the cases subjected to the treatment which he advocates. That the risks are considerable is amply evidenced by the recent unfortunate experience at Guy’s Hospital, where two patients died from tetanus in the course of treatment by this method. Both patients—the one, a carter of 37, and the other an engineer’s labourer, of 33—were the subjects of aortic aneurysm; but, though these men died from tetanus, a third patient, who was, about the same time, treated in the same way for the same disease, was discharged from the hospital apparently cured. Too much stress must, therefore, not be laid upon the unfortunate result in the cases referred to; and it must not be concluded that the tetanus spores, highly resistant though they are well known to be, existed in the gelatine used, which had been carefully subjected to prolonged and thorough processes of sterilisation. The fact of the third patient having escaped such an untoward complication is, indeed, of itself almost sufficient evidence that the contamination arose not from the gelatine, but from some outside source which it was found impossible to trace. Though Lancereaux’s plan of treatment seems to have failed in some cases, there are many in which it has been attended by results sufficiently brilliant to attract attention and to warrant hopeful anticipation. Where an aneurysm is so situated that it can be dealt with by surgical methods, these will probably continue to be regarded as the safest and most trustworthy means of treatment to which the patient can be subjected; but in cases—and they form no small proportion of the sum total of this formidable disease—which are beyond the reach of the surgeon’s aid, any means by which the misery and suffering may be mitigated, or the risk of sudden death from rupture lessened, must be welcomed as an advance in the progress of the therapeutic art.

In a paper communicated by Lancereaux and Paulesco to the Bulletin de l’Academie de Medicine in July of 1901, it was pointed out that non-success often arises either from faulty application of the method or from its use in cases of fusiform aneurysm, where the chances of amelioration are comparatively slight. In 1895, M. Dastre claimed to have proved that the injection of a solution of gelatine into the veins of a dog rendered the blood more coagulable; but his results are not universally accepted, and it seems not yet to be certain how far the injection of gelatine into the cellular tissue of human beings can produce an effect on blood-coagulability. Nevertheless there is a considerable mass of evidence which goes to prove that it undoubtedly does exert such an influence. It is difficult otherwise to explain the marked improvement as regards their most urgent and painful symptoms which aneurysmal cases experience when treated by it. If a restricted diet and complete rest in bed are associated with the use of gelatine, improvement from these measures may readily be fallaciously ascribed to the injections; but cases do occur in which patients have failed to respond favourably to the ordinary and accepted dietetic, drug, and rest treatment, and yet have experienced striking relief when to these influences have been added that of gelatine injected into the intermuscular spaces.

The first use of gelatine as a curative injection for aneurysm was reported by Lancereaux to the French Academy of Medicine in June of 1897. The patient was an embroiderer, of 45, who presented all the classical signs and symptoms of an aneurysm of the ascending aorta, which had advanced to such a stage that the skin over the surface of the tumour was thin and ecchymotic. On January 20th a first injection of 20 cc. of a sterilised saline solution of gelatine was administered into the subcutaneous tissue of the left buttck. Following on this, Lancereaux’s report tells us, there was produced a little redness at the seat of injection, and the temperature rose to 38° C. The next day a normal condition was re-established, and in addition it was demonstrable that the tumour had become manifestly more firm and the pulsations less forcible. For some days

(a) Paper read before the Royal Medical and Chirurgical Society, June 22nd, 1903.
afterwards it diminished a little in volume, and—what was still more remarkable—the pain completely disappeared and the patient was able to assume the dorsal position without experiencing either oppression or paroxysmal cough. But soon the tumour resumed its original dimensions; its walls again became soft, and the blood could once more be felt forcibly driven against the skin, while coincidentally the intercostal pains reappeared.

A fresh injection of 150 cc., made on February 15, was followed by the same result as the first, but this time without reaction, either local or general. Subsequently, eleven similar injections were given at intervals of a few days, the last being administered on May 7th. By that time the tumour had diminished by two centimetres in the vertical and one centimetre in the transverse diameter; it was very firm, and, on palpation, though pulsations could not be felt, they were pulsations en masse transmitted by the aorta, and not expansile pulsations such as the patient presented when first seen.

The man no longer suffered any pain, and so strongly insisted on going out that he was discharged on May 25th. "In face of this result, say Quenu, "which was achieved under severe observation, it is difficult, if not impossible, despite therapeutic scepticism, which is not inconsistent with an ardent faith in medicine, to refuse to the means employed a substantial utility, for without it our patient would have perished. Therefore we do not hesitate to recommend this method of treatment in cases, in three of which complete cure had resulted, while in the remaining two death had occurred, in one instance from rupture of the sac, and in the other from uræmia. He thus sums up the conclusions which were to be drawn from this further experience:—"Gelatine introduced into the subcutaneous cellular tissue penetrates the blood, which it renders more than normally coagulable; and since this blood encounters in the aneurysmal pout two conditions favourable to coagulation—namely, a retardation of its current, and a vascular wall which is frequently uneven—there is produced a more or less abundant formation of clots, which in time fill up the sac. Ultimately these clots contract, the pouch which contains them diminishes in size, and the pressure symptoms to which it gave rise diminish and disappear. If softening of the clot takes place the blood penetrates between it and the walls of the sac, and the tumour is reproduced. Under such conditions, fortunately, coagulation again takes place readily. Gelatine, therefore, constitutes an excellent therapeutic agent which, if it does not cure true aneurysms, at least favours the natural process of their cure."

At a subsequent meeting of the French Academy, on October 11th, 1898, Lancereaux presented another report on this new treatment, and recorded in detail the cases, in three of which complete cure had resulted, while in the remaining two death had occurred, in one instance from rupture of the sac, and in the other from uræmia. He thus sums up the conclusions which were to be drawn from this further experience:—"Gelatine introduced into the subcutaneous cellular tissue penetrates the blood, which it renders more than normally coagulable; and since this blood encounters in the aneurysmal pouch two conditions favourable to coagulation—namely, a retardation of its current, and a vascular wall which is frequently uneven—there is produced a more or less abundant formation of clots, which in time fill up the sac. Ultimately these clots contract, the pouch which contains them diminishes in size, and the pressure symptoms to which it gave rise diminish and disappear. If softening of the clot takes place the blood penetrates between it and the walls of the sac, and the tumour is reproduced. Under such conditions, fortunately, coagulation again takes place readily. Gelatine, therefore, constitutes an excellent therapeutic agent which, if it does not cure true aneurysms, at least favours the natural process of their cure."

At home the treatment does not seem, so far, to have been received with much enthusiasm, nor is it justified with much probability; stray cases are recorded here and there throughout our medical literature of the past two years, and I understand that Dr. Maguire, of the Brompton Hospital, is about to publish the results of his experience, in a short series, of patients treated by the gelatine method.

By experiment Lancereaux fixed the quantity of gelatine necessary to obtain a sufficient coagula- bility of human blood at 250 cc. of a saline solution containing two grammes per cent. of gelatine; and from experience he found that several months are required during which at least from twelve to fifteen injections are necessary to achieve satisfactory results.

According to Huchard, a 1 per cent. is safer than a 2 per cent. solution of gelatine, and an interval of from eight to ten days is advisable between each injection. I have not found it possible to introduce into the subcutaneous tissue more than 100 cc. without producing local pain, and I have observed that even this amount must be injected slowly—over an interval of ten or twelve minutes—in order to avoid discomfort and over-distension of the skin. A considerable swelling is produced at the seat of injection, but this entirely subsides within from twelve to twenty-four hours. The inner aspect of the thigh has been found a more convenient situation than the buttok; in one case, where the pectoral region was chosen, the patient complained of so much pain that the experiment was not repeated. In all these four cases the patient was kept during his course of treatment confined to bed, and the injections were repeated twice a week.

Concurrently with the gelatine treatment, iodide of potassium was given in ten-grain doses three times a day, and with it were combined minum doses of 1 in 100 solution of nitro-glycerine whenever the pulse tension became excessive or when there were anginal symptoms.

The nitrogenous elements of the daily dietary were minimised, and the amount of liquid allowed was kept within narrow limits.

The apparatus used by Lancereaux is somewhat complex; it will be found fully described at page 358 of the fourthieth volume of the "Bulletin de l'Académie de Médecine." At Greenwich we contented ourselves with a glass syringe of 100 cc. capacity, having metal fittings and an adjustable piston.

The gelatine solution was made after the following method, for the description of which I am indebted to Mr. Hart, who was responsible for its preparation:—"Gelatine, 1 ounce; chloride of sodium, 131 grains; sterile distilled water to 50 ounces. These are put into a flask, plugged with cotton-wool, allowed to stand an hour or two for the gelatine to soften, and then the heat from a water-bath applied to effect solution. The flask is afterwards placed in a steamer for an hour, and is subjected to this treatment on three consecutive days. Immediately before use the solution is boiled—100 cc. is again re-steamed. Every precaution is taken to ensure complete coagulation of the solution, but also of the patient's skin and of the instruments used."
MINERS’ PHTHISIS. (a)

By THOMAS OLIVER, M.D., F.R.C.P.,
Physician to the Royal Infirmary, Newcastle-upon-Tyne.

APPLYING the term miners’ phthisis to the deeply pigmented and somewhat solid state of lung found in miners who during life have exhibited signs and symptoms of pulmonary disease of a moderately chronic character, Dr. Oliver said that, while the malady had generally been regarded as the result of breathing a dust-laden atmosphere, it was much less common now than fifty or sixty years ago. This circumstance he attributed to the improved system of ventilation of our coal-pits. Miners’ phthisis as a morbid entity has been known since 1703, when Ramazzini drew attention to it. In 1860 Peacock proved microscopically and chemically the identity of the particles of dust found in the lungs with the dust of the atmosphere in which the patient had worked during life. There was sufficient evidence to show that pneumokoniois was a dust disease and due to occupation, also that the phthisis bore a distinct relation to the form and character of the dust inhaled, for, as Hirt had shown, in each hundred workmen suffering from pulmonary consumption caused by dust, metallic dust was responsible for 28 per cent. of the cases, mineral dust for 25-2 per cent., animal dust for 20-8, and vegetable dust for 13-3 per cent.

There are two ways by which the pathology of miners’ phthisis could be studied. (1) Pathological inquiry in man, and (2) physiological experimentation in animals.

The dust that is inhaled under ordinary circumstances gets caught on the nasal, pharyngeal and laryngeal mucous membranes. Should particles of dust reach the trachea and bronchi, they become entangled in the mucus secreted by the tubes, and are either wafted outwards by ciliary motion, or are coughed up. This barrier apparently becomes broken, for as life proceeds, the lungs of all persons, of town dwellers especially, become more or less pigmented. Discoloration of the lung is quite consistent with health. There must be something superadded to the pigmentation to cause the lungs to become pathological. When particles of dust reach the pulmonary alveoli Dr. Oliver showed that while the amount of local reaction was determined by the form and character of the dust particles, there were present in the alveoli large wandering cells which were distinctly phagocytic in their nature. By these cells particles of coal dust were swallowed and transported into the plasma spaces of the alveolar wall and into the lymphatics, by means of which they were carried to the bronchial glands. The pulmonary lymphatics run under the pleura, in the interlobular septa and on the walls of the blood-vessels and small bronchi.

Dr. Oliver exhibited drawings of microscopic sections of lung taken from a Transvaal gold miner, whom he had seen in consultation with Dr. Dodds, of Cramlington. In the lung, in addition to marked fibrosis, there can be seen large cells filled with black granules, some of which have wandered outside the alveoli. These cells distinguish other than the black particles. Newly-formed fibrous tissue can be seen interpenetrating itself between these large cells. To

Dr. Oliver pneumokoniois is not a tuberculous disease. Tuberclcle is often met with in miners’ phthisis, but when present it is an accidental and, therefore, a secondary infection.

Speaking of the causation and experimental production of anthracosis, Dr. Oliver eliminated the gases liberated by the coal, and those pigments as a result of the explosives used in the mine, as playing any part in pneumokoniois. Claissen and Jouves’ experiments upon animals that had inhaled the smoke from burning lamps were alluded to, in so far as confirming the previous statement, viz., that the lungs could become deeply pigmented and yet be maintained and no pathological alteration occur in the lung tissue. Trotter, of Bedlington, looks upon anthracosis as an epiphenomenon in pulmonary disease, and attributes the fibrosis not so much to the coal itself as to the accompanying particles of stone from the sandstone strata and sedge clay, &c.

The most important point is how far miners’ phthisis is or is not a tuberculous lesion. One of the strongest advocates of the tuberculosis theory of anthracosis is Dr. Triper, of Lyons. To him tubercle is not a coincidence nor a secondary infection, but the principal cause of pneumokoniois. Since Koch discovered the tubercle bacillus there has been little written upon the subject of miners’ phthisis. One of Triper’s patients was a miner who had worked for fifteen years in the Mont Cenis and St. Gothard tunnels. The construction of both these tunnels was attended by a great loss of human and equine life. Many of the miners died from pulmonary disease and from anaemia due to ankylostomiasis. The tunneling of the Simplon, which is now present, has been conducted with a remarkable freedom from tuberculous lung disease—a circumstance which is attributed by Dr. Volante, of Iselle, to the excellent system of ventilation that prevails. There is plenty of smoke in the tunnel and the air is fouled by the respiration from the men and horses, but as the perforation in the rock is accomplished by machine drills under hydraulic pressure, and water is automatically sprinkled on the débris at the time of the drilling, there is no dust, and to this circumstance is largely due the remarkable absence of lung disease among the miners.

After renewed allusion to the part played by phagocytes in conjunction with dust in causing pneumokoniois, Dr. Oliver summarised his conclusions thus:

1. Miners’ phthisis is not caused by the inhalation of any of the gases present in the mine.
2. In pneumokoniois there may be not only excess of fibrous tissue, but even cavities and tubercle.
3. The disease is, however, non-tuberculous.
4. Accepting this view of the pathology of the disease, there is hope that by improved ventilation and by allaying the dust with water, miners’ phthisis may still further be diminished.

Suicide of a Medical Man.

An inquest was held at Leeds last week on the body of Mr. Arthur Cecil Brigg Pierson, M.R.C.S., L.R.C.P., aged 31, who had committed suicide while under treatment at the Infirmary for insomnia. He had been suffering from mental depression, but no suspicion of suicidal tendencies was entertained.

(a) Address introductory to a Discussion at the Swansea meeting of the British Medical Association, July, 1903.
HUMAN EVOLUTION:
WITH ESPECIAL
REFERENCE TO ALCOHOL. (4)

By G. ARCHDALL REID, M.B., C.M., F.R.S.E.

I propose to place before you a series of propositions which appear to me more or less self-evident and undeniable. But the conclusion they lead to is not self-evident, and has, indeed, been strongly denied. The strength of any chain of argument depends on the strength of its weakest link. The most effective way of proving the correctness of any chain is to snap that weakest link. The least effective way is to declare, in general terms, that the chain is devoid of strength. I venture, therefore, to commit the impertinence of directing your attention beforehand to the separate links of the chain rather than to the chain as an entirety; to the series of propositions on which my argument is founded rather than to the conclusion by which they are welded into a whole. If the propositions are individually true, then the conclusion follows inevitably; but if a single fact of deduction is erroneous, you can easily destroy the conclusion by demonstrating the initial error.

1. The first of these propositions is this, that all the races of mankind sprang originally from a common stock. I imagine no one will deny the truth of this proposition. It is embodied not only in all popular, but in all scientific teaching. The truth of it is demonstrated scientifically by the fact that every race can interbreed with every other. As is well known, only closely related species, for example, I need not enter on, are capable of having offspring in common.

2. The second proposition is that since their divergence from the common stock all the races of mankind have undergone and are undergoing a progressive and continuous change. This is evident from the fact that, though originally all were alike, there are now big races and small, white races and black, races highly resistant to this or that disease, and races less resistant; and so forth.

3. The third proposition is that these changes have been of an adaptive and protective nature. In other words, every race has become especially fitted to the environment in which it has undergone evolution. Thus the Equinoxians, to-day, are better able to resist cold than the Arab, who is better able to resist heat. The Londoners perishes of malaria in West Africa; the West African perishes of phthisis in London.

4. The fourth proposition is that this evolution has been due solely to the survival of the fittest; in other words, to the natural selection of genital variations. To this proposition I do not expect immediate or complete assent. Many of my audience will deny, for instance, that the negro race has become black solely because naturally dark people survive and have offspring in the Tropics in greater numbers than naturally fair people. They will maintain rather that the adaptation in the skin, which exposure to the sun produces, has been transmitted from parent to child, and that thus, in the course of generations, the original degree of pigmentation has been accentuated to almost absolute blackness. However, I do not propose to ask your assent to the entire doctrine of natural selection. As to

that I content myself by remarking merely that belief in the doctrine in its entirety is now almost universal among that section of biologists who have devoted especial attention to questions of heredity and evolution. The only proposition in this connection to which I shall ask your assent is that certain phases of human evolution are due solely to the survival of the fittest. In doing so I shall not pass beyond the bounds of everyday medical knowledge.

5. The fifth proposition is that to some extent every individual human being differs congenitally from every other human being in bodily and mental peculiarities—in height, in strength, in colour, and in mental vigour, for instance.

6. The sixth proposition is that parents on the whole tend to reproduce their like. Thus big people tend to have big children, and little people little children. When the ancestry is permissive the reproduction of the parental trait is almost invariable; thus negro parents are almost invariably, black offspring. When, as regards any particular trait, the ancestry is mixed, the reproduction is less certain; thus, among us the offspring of parents may be smaller, or the offspring of fair people darker, than their parents. Nevertheless, the rule holds in a great majority of instances.

7. The seventh proposition, which follows as a corollary to the fifth and sixth, is that human individuals differ in their power of resisting diseases, and that offspring tend, with variations, to inherit parental powers and weaknesses in this particular. Thus, in England, some people are much more resistant to phthisis than others. The truth that parents tend to transmit their powers or weaknesses to offspring is conspicuously shown by such facts as that negroes, as a race, are more resistant to malaria than the British, whereas the British are more resistant to phthisis.

8. The eighth proposition is that races are resistant to any given disease precisely in proportion to the length and severity of that disease in the region. Thus the British, who for thousands of years have been afflicted by phthisis, measles, and whooping-cough, are much more resistant to these diseases than the inhabitants of the Western Hemisphere, who have known them only during the last few generations, and are now being exterminated by them.

9. The ninth proposition is that parental disease does not affect in any way, for good or evil, offspring subsequently reproduced, at any rate through inheritance properly so called. I fear this proposition is not at first sight self-evident, and I am aware that the mass of professional opinion is at present against it. Pneumonia, gout, phthisis, syphilis, pellagra, and all the complaints have been alleged as causes of filial degeneration. Nevertheless, I venture to insist that this prevalent professional opinion has no foundations save an ancient superstition and a certain amount of bad observation which the superstition rendered inevitable. At the present day a mass of evidence may be deduced against it. The laws of heredity which govern the lower animal and plant worlds do not differ from those which govern man. Biologists have found that the offspring of asexual reproduction are always exact copies of their parents, no matter what conditions the parents may have been subjected to. Thus the summer generations of aphides, which are produced by the female
without the intervention of the male, are exact copies of the parent. So also plants propagated by buds, suckers, or slips show practically no variations. On the other hand, the offspring of sexual reproduction vary always, and it may be enormously. Thus the puppies of a single litter may be of very different shapes and colours. So also the variations of plants which arise from seeds are very great. Biologists have concluded, therefore, that the sole cause of variation, the sole agency which brings about a difference in offspring at birth differ from what their parents were at birth, is the intermixture of dissimilar germ plasms; the union of dissimilar individuals resulting in offspring dissimilar to both. Again, human beings undergo great changes between puberty and old age. Yet the offspring of aged parents cannot be distinguished from those of boys and girls. Most convincing of all, however, is the following:—If parental disease affects offspring subsequently born, then the variation thus produced is a congenital one. But, as is well known, congenital variations tend to be transmitted to descendants. Under such conditions a race afflicted by any disease would undergo rapid and sometimes not very obvious change. We know that this is not the case. On the contrary, disease, so far from weeding out, actually strengthens a race afflicted by it. At any rate, it always strengthens the race unless the conditions are so severe that no time is allowed for the operation of natural selection. Indeed, gentlemen, if you think the matter over I think you will see that the universal and universally accepted doctrine of natural selection is incompatible with the doctrine that parental states of body and mind affect offspring subsequently born. If one is true, the other cannot be true. All species are at times subjected to disease, heat, cold, want, hardship, and other injurious agencies. If these affect and spring from these, there could be no natural selection, since there would be no favourable variations for natural selection to act on. All variations would be unfavourable.

10. The tenth proposition is that just as people differ in all other respects, so they differ in their susceptibility to the charm of alcohol. This is a very important proposition, but certain considerations are very frequently ignored. We know that all drunkards are so susceptible to the charm of alcohol that they crave intensely for excessive indulgence, whereas most moderate drinkers are so little susceptible that they do not crave for excessive indulgence. I know, for instance, that I never need to resist the temptation to get drunk. I simply have it not. I have no doubt that most other people in the room are constituted as I am. Otherwise they must go about craving ardently for drunkenness, but strenuously resisting the temptation.

11. The eleventh proposition is that as a rule people drink in proportion to their desires. This is obvious. The greater the temptation, the greater liability to fall.

12. The twelfth proposition is that alcohol when taken to excess is a poison, and the cause of a huge mortality. Of course, like all other toxic substances, it poisons most those who take it most in excess.

13. The thirteenth proposition is that parental intemperance, like disease, does not affect offspring subsequently born. I exclude of course, the children of mothers intemperate while pregnant. I am discussing questions of heredity, and heredity is concerned with sperms and ova, not with embryos. I am perfectly aware that it is a prevalent opinion that parental intemperance does affect offspring subsequently born, and that various statistics have been published in support of this opinion. But statistics, drawn up by gentlemen who believe they are supporting an undisputed fact, are very apt to be erroneous, since the various sources of error are not sufficiently taken into account. Even within the truth in my belief that the statistics in question have been published mainly by gentlemen who worked before exact observations on heredity had been made, or who were unaware of them. If it be true that parental intemperance affects offspring, then we have here an exception to an apparently universal biological law. However, to ascertain the truth definitely, we have only to investigate the effect of alcohol on races which have long used it. If offspring are affected, then races which have long used alcohol should be degenerate and tending towards extinction. On the other hand, if offspring are not affected, races that have longest used alcohol ultimately, through the weeding out of the unfit, be the least inclined to excessive indulgence, the least susceptible to the charm of drunkenness, of all races. The evidence on this subject is very clear. The Jews, Greeks, Italians, South Frenchmen, Spaniards, and Portuguese, who have longest had an abundant and continuous supply of alcohol, are the most temperate people. North Americans and others who have had a less plentiful supply are less temperate. Whereas some savages and others who have had little or no experience of the poison are the most intemperate of all.

14. The fourteenth proposition, then, is that alcohol, like disease, is the cause of an evolution productive against itself. Drunkenness in the ancestry is the cause of the tendency of the descendants. The case of alcohol is exactly paralleled by that of opium. Opium has been in use for many centuries in India. The Chinese have used it for two hundred years. It has lately been introduced into Burma, Australia, and some Pacific islands. Practically speaking, natives of the latter have very frequently taken opium and still take it to excess, though the majority are much more temperate than formerly, when enormous harm was done. The Burmans, Australians, and Polynesians take it to such excess that its use is invariably forbidden to them, though permitted to foreign immigrants to their countries.

15. The fifteenth proposition is that the causes ordinarily alleged for racial sobriety—climate, civilisation, education, and so forth—are erroneous. I have not time to deal adequately with this point, but if anyone disputes it, I am prepared to furnish chapter and verse.

16. The sixteenth proposition is that repressive legislation is useless among civilised nations. It has been tried by scores of governments, on hundreds of occasions, during thousands of years, and has invariably failed, except among the Mohammedans. With them the success, which has only been partial and can be only temporary, has been achieved by means which have made them harbarous as well as temperate. Moreover, the Mohammedans have not always been obeyed. I fear in this instance also I have not time for adequate discussion. Once again I must content
Co-operation in the study of metritis. (a)

By DON POLICARPO LIZCANO Y GONZALEZ.

[Specially reported for The Medical Press and Circular.]

The investigations made on the subject of metritis to elucidate the correlation between the anatomical lesions and the symptoms of the disease have not yielded much fruit. Progress has not been facilitated by the different opinions expressed by specialists and by the different interpretations put on the observed phenomena. Bacterial effects are seen in the altered state of the connective tissue, and the results of infection are found in the evidences of malnutrition, blood stagnation, and nerve irritation; these infective results are found in glandular tissue. When the two etiological factors are at the one time acting, a glandular-interstitial lesion results. Such are the views of many experimenters engaged in the study of the bacteriology of the disease and of its clinical aspects. To-day it is difficult to diagnose the forms of metritis by the anatomical lesions they present; but in the meantime the bacteriologist and Koch, which produces symptoms little characteristic of so definite a micro-organism. Indeed, the bacilli usually disappear and the alteration they have produced alone remains, leaving nothing but uncertainty on this most important scientific point. Our investigations were conducted on 96 cases, and each case was studied under three heads: its etiology, its anatomy, and its clinical aspect.

In considering the etiology, without making a bacteriological examination we, from the clinical study, divided our cases into two groups—bacterial, presumably the cause of puerperal fever; and the other, probably outside the range of infection, produced by the occurrence of the menopause, retroversion, or fibroma.

We divide the anatomical cases met with into five groups, characterised, according to their microscopic characters, by the following alterations:

1. Glandular structure, 17 cases; 2. interstitial structure, 7 cases; 3. glandular tissues, 40 cases; 4. glandular tissue completely absent, 25 cases; 5. glandular tissue scanty, 12 cases.

The principal symptoms were leucorrhoea and menorrhagia. The symptom most marked has been meno-haemorrhagia in 83 cases, and leucorrhoea in 13 cases. The etiological-anatomical relations of 78 cases were:

Infections, puerperal—Mixed lesions, 31 cases; absence of glandular tissue, 10 cases; notable deficiency of glandular tissue, 4 cases; lesions of glandular tissue only, 8 cases.

Of the 31 cases of mixed lesions, 16 were post-partum and 15 were post-abortum. Of the 10 cases of total absence of glandular tissue, all were post-abortum. Of the 4 cases showing but little glandular tissue, all were post-partum. The non-infectious cases, of which there were 25, we divide into three groups:

1. Menopause—Total absence of glandular tissue, 6 cases; interstitial tissue, 3 cases; purely glandular tissue, 2 cases.

2. Retroversion—Purely glandular, 4 cases; mixed (glandular and interstitial tissue), 3 cases.

3. Fibromata—Glandular, 3 cases; sparsely glandular, 3 cases; total absence of glandular tissue, 1 case.

If the 78 cases are divided into three groups according to the classification of Ruge, we have—Glandular lesions, 17; interstitial lesions, 27; and mixed lesions, 34.

In considering the influence of the cause, infectious or not, upon the anatomical structure, we notice that glandular hyperplasia occurs with great frequency in the non-infectious cases. In 23 cases of non-infectious metritis, 9 were of the glandular hyperplasia type (16 per 100). In the 53 cases of infectious metritis, 8 were of the glandular hyperplasia type (14.7 per 100). The lesions most marked in the connective tissue were also most common in the non-infectious cases. In 25 cases of non-infectious metritis, 13 had marked alteration of the connective tissue. In the 53 cases of infectious metritis, 14 showed marked alteration in the connective tissue (26 per 100).

We have found the mixed lesions to preponderate in infectious metritis. In 53 cases of infectious metritis, 31 had mixed lesions (58 per 100). In 26 cases of non-infectious metritis, 3 had mixed lesions (12 per 100). The influence of labour on the symptoms and lesions of metritis—Of 28 cases we found that 9 were nullipara and 19 were multipara. The anatomical lesions in these cases were—Glandular hyperplasia, 6 nullipara and 9 multipara; interstitial hyperplasia, 2 nullipara and 4 multipara; mixed hyperplasia, 1 nullipara and 6 multipara. The most marked symptoms were leucorrhoea in 3 nullipara and 6 multipara; and haemorrhage in 6 nullipara and 15 multipara. In the five groups the histological lesions, with the causes and predominating symptoms, were:

1. Glandular.—Under this name we include all cases in which the lesion was limited to the glandular tissue without any appreciable alteration in the connective tissue. Of the 17 cases under this heading, we found 12 in which the glandular tissue looked quite healthy, the only deviation from the normal being in the irregular shape of the gland and the larger size of its cavity. All of them preserved an unbroken cell lining and an untouched basal membrane. The epithelium that covered them was in no instance inflamed. In the 5 remaining cases there were marked changes in the glandular tissue, but the glands were less dilated and their outline was less irregular, and they contained two or three layers of cells.

The causes of these cases of metritis were in 8 patients puerperal, in 4 retroversion, in 3 fibroma, and in 2 the menorrhagia. The patients of this group were of a sanguine temperament and a strong constitution; their age ranged from thirty-six years to fifty; the case of longest dura-
tion was of two years and two months' standing. Six of the cases were post-abortum. The most marked symptoms were hemorrhage in 15 cases (88 per 100), leucorrhœa in 2 cases (12 per 100).

2. Interstitial lesions purely. — Under this heading we include such cases as have lesions confined to the connective tissue, without any glandular tissue being implicated. Five of the 7 cases examined had greatly dilated blood-vessels, with sanguinolent infiltration of the mucosa. The cellular changes corresponded to the period of acute inflammation of the conjunctival tissues. The causes of the interstitial metritis were in 4 cases diseases of the annexes, and in 3 cases the menopause. The patients were of middle age, except those who suffered at the menopause. One of the cases was of three years and eight months' standing. The usual marked symptom was uterine hemorrhage.

3. The mixed lesions. — In this, the largest, group the lesions of the stroma and the glandular tissue were marked. The glands, apart from their being misshapen, were filled with cells of various forms and sizes; some of the cell cavities were much reduced in size and very irregular in form. The interstitial tissue was infiltrated with swollen cells, which broke through the glandular cavity and became numerous in numerous instances; we found no vascular dilatations such as are described in the preceding group. The causes for this form of metritis we ascribe as follows—Puerperal in 31 cases, retroversion in 3 cases, and perimetritis in 5 cases. All these patients were of middle age, multiparas, of sanguine temperament. The condition lasted from one to two years; in 5 cases it was of post-abortum origin. The principal symptoms—menorrhagia in 36 cases (87 per 100), leucorrhœa in 5 cases (13 per 100.)

4. Complete absence of glandular tissue. — The lesions of the stroma, apart from the infiltration of embryonic cells, showed in half of the cases examined great dilatation of the sanguineous vessels, some of which were destroyed. In this group are included three cases of papilloma and one of pseudo-membranous dysmenorrhœa. The etiology of these twenty cases is as follows—Puerperal, 10 cases; menopause, 6 cases; fibroma, 1 case; and stenosis, 3 cases. The ages of these patients ranged from twenty-six years to thirty-eight years, except the menopause cases. They were all of a sanguine temperament. The disease was in every case of some months' standing, and all the puerperal cases were post-abortum. Two of the cases were amenorrhagic and nullipara. The most marked symptoms were menorrhagia in 17 cases (85 per 100) and leucorrhœa in 3 cases (15 per 100).

5. Sensible diminution of the glandular tissue. — The glandular tissue in the cases of this group is markedly diminished in amount; in fully half of the whole number the tissue is atrophied, and in some the basal membrane has disappeared. The etiology of the twelve cases of this group is as follows—Puerperal, 4 cases; fibromata, 3 cases; perimetritis, 3 cases; and in 2 cases it is unknown. The patients were from forty-five years old to forty-eight years, of a sanguine temperament; and the duration of the disease was from four to eight months. The principal symptoms were menorrhagia in 9 cases (25 per 100), leucorrhœa in 3 cases (25 per 100). Giving due weight to the above cases, may we not, from their study, find grounds for tracing a true connection, anatomical-

etiological—clinical, for metritis, and may we not formulate the conclusions arrived at this?—

1. The anatomical lesions most frequent in metritis are those which affect the glandular tissue (hyperplasia and atrophy).

2. Those that affect both the glandular and connective tissues (mixed) are common.

3. There are few histological lesions confined to the interstitial tissue to the exclusion of the glandular.

4. Histological lesions confined to one tissue, glandular or interstitial, are more frequent in the non-infectious forms of metritis.

5. The lesions of mixed tissues are more common in the metritis of an infective origin.

6. The lesions of mixed tissues are principally due to injuries consecutive to labour and abortion.

7. The absence of glandular tissue is most frequently found in cases of post-abortum metritis.

8. The glandular tissue is found to be atrophied in the metritis of the critical age, whatever may be its origin (puerperal, fibromata, and so forth).

9. Uterine hemorrhage is the most marked symptom of metritis (86.4 per 100).

10. Leucorrhœa, as a symptom, is of little value in metritis (occurring in 13.5 per 100).

11. Haemorrhage occurs more frequently in multipara and leucorrhœa in nullipara.

12. Although hemorrhage is found in all forms of histological metritis, it appears to be more directly dependent on conjunctival lesions than on glandular ones.

Clinical Records.

A CASE OF

ACUTE CEREBRO-SPINAL MENINGITIS.

By Cecil Wall, M.D., M.R.C.P.,

Physician to the Eastern Dispensary.

Henry R.—Set. 35. admitted March 27th, 1901, died April 13th, 1901. Early in November, 1900, he began to have aches and pains all over, chiefly in the head, and was feverish; one week later he had violent pain in the head and neck, and some vomiting, chiefly after food. He was treated at home for a fortnight, without improvement, and was then sent to the Brook Fever Hospital with a diagnosis of enteric fever. The medical officer of this hospital kindly provided the following note: —

The patient was admitted on December 11th, 1900, with a history of a severe headache of three weeks' duration. On admission the patient was delirious, and there was pyrexia, which persisted for two weeks; chief symptoms—stagnation of urine; there was marked tendency to constipation. After the first fortnight there was vomiting every two, three, or four days, often without any apparent relation to food.

Widal's test was negative on December 12th, 13th, and 21st. The knee-jerks were present throughout; the pupils were equal and reacted to light, and with accommodation; the fundi were clear.

There was no nystagmus or deviation of the eyes to the side. He was drowsy, helpless, and slept much. He was sent home at the beginning of March, as there was no improvement, and the diagnosis of enteric could not be sustained. His wife thinks that he was worse on discharge than on admission to the fever hospital. He remained at home for three weeks. Seeing that he was getting more helpless, while the headache and vomiting continued, he was brought to the London Hospital on March 27th, and admitted under the care of Dr. Hadley.

(a) From a Paper read before the Royal Medical Chirurgical Society.
On admission he complained of frontal and occipital headache, which was increased on tapping the skull with the fingers. He still lay in bed, taking no notice of his surroundings, and moaning from time to time. He understood questions, but his answers were unreliable, and showed that he was only anxious to be rid of them.

There was considerable general wasting. No facial, ocular or other palpebral affections were noticed. There was some nyctagmus on extreme movements of the eyelids. The knee-jerks were much increased, especially on the right side; on this side alone ankle-clonus was obtained. The plantar reflexes were both times flexor, the toes moving downwards. With the hips flexed to a right angle, the knees could be extended to about 145°. The fundi were normal. There was some hyperaesthesia over the neck and back of the head. There was no photophobia. There was no evidence of intra-thoracic or abdominal disease. The urine was normal.

The temperature on admission was 100°F., and continued to be irregular, ranging from 97° to 101° until his death. There was occasional vomiting throughout; sometimes there was incontinence and sometimes retention of urine; constipation was marked. The irritability continued, and the headache showed occasional signs of intermission.

On April 11th the patient had a right-sided fit, and later in the day had three more. After the last fit he remained stertorous, with divergent strabismus, contracture of flaccid pupils (reacting to light), and rigidity of the arms and right leg. On April 12th lumbar puncture was performed, three ounces of fluid being drawn off in which the diplococcus meningitidis intracellularis was found to be present. On April 13th he had another fit and died shortly after. The total duration of the illness was over five months.

The post-mortem examination revealed no gross pathological changes except in the cranial cavity. On removing the dura mater there was found to be a small hemorrhage into the pia mater at the upper part of the right Rolandic area. The convolutions were much flattened. There was a large quantity of clear fluid in the ventricles, with thickening of the arachnoid. There were adhesions between the prefrontal lobes and in both Sylvian fissures. There was a large quantity of clear fluid in the ventricles, and at the lowest part of each posterior cornu there was a tiny mass of green lymph.

The Out-Patient Departments.

WEST LONDON HOSPITAL.

Dermatological Cases under the care of Dr. P. S. ABRAHAM.

[Reported by D. G. N. MARCHEK.]

I.—Kelion of Scalp underlying Impetigo.—A girl, aged 11, came with a very crusty, neglected condition of the scalp which her mother stated had been present for about a month. When this had been cleared off by frequent washings with soft soap and the application of ammoniated mercury ointment, there was to be seen an extensive, bogggy condition of the scalp, which was oozing pus in many places. Several short stubby hairs were projecting from the softened areas, but a careful microscopic examination failed to reveal the presence of any fungus. However, tinea was strongly suspected, and on the child's next appearance the search was successful, the Megalosporon endotrichus being found.

This case is instructive from many aspects. In the first place, tinea tonsurans should ever be borne in mind whenever crusts are persistent upon a child's scalp. Many times it happens that what is only thought to be a simple impetigo or a pediculosus eventually turns out to be a case of ringworm. Accurate diagnosis, therefore, cannot be given until thorough microscopic examination of any suspicious hairs has been made and repeated if necessary.

The danger of pronouncing tinea to be absent after only one examination in a doubtful case is also well illustrated by this case, where the knowledge of the general principle that success in dermatological treatment depends almost entirely upon accurate diagnosis.

Another point of importance is that the inflammatory condition of the scalp known as kerion is most commonly produced by ringworm, and in some respects it is more advantageous than otherwise, provided, of course, that the follicular layer is not destroyed.

This child was treated with a 10 per cent. ointment of carbolic and salicylic acids for induction.

II.—Basis Disease.—A girl, aged 18, came for swelling and ulceration of the legs. The history was that a brother and a sister suffered from "weak chests," and an uncle died of "consumption." She had had no previous illnesses. Five years ago the legs began to be painful and to swell a little, and three years later small ulcers appeared about the ankles. On examination, both legs were swollen, though there was no appreciable pitting on pressure. The colour of the skin was somewhat dusky and mottled. A short distance above the malleoli were two or three shallow, indolent-looking ulcers, while on the anterior surface of the tibiae were several indurated erythematous patches which were painful to the touch. There were no varicose veins present. There were no other cutaneous lesions, and there was no evidence or history of syphilis, congenital or acquired.

The general appearance of this case strongly resembled those of syphilis, and indeed this disease is very frequently diagnosed and treated as such without benefit to the patient. This girl, however, showed no signs of syphilis elsewhere, in skin, eyes or teeth. Moreover, although the ulcers were somewhat "punched out," an attribute usually supposed to be characteristic of specific ulcers, yet these were not of serpiginous outline, and they also tended to become situated as much upon the posterior aspect of the limb as the anterior, while the region about the knees was quite unaffected.

The small indurated patches of erythema should suffice to render the nature of the case clear, and it is from these that the disease takes its name, having been described by Baxin in 1861 as Erythème naturel des corks-fleuris.

The disease, which is known as erythema nodosum, is readily distinguished from Baxin's malady by its acute nature, the pinker colour of the patches, its occurrence in rather younger subjects, and its more ready response to treatment.

As this girl was rather pale, and taking into account her well-marked tuberculous family history, she was given the syrup of the phosphate of potash, and locally an ointment of the yellow oxide of mercury.

Pathologically, erythema induratum scrofulosorum is a tuberculide, that is, a cutaæous affection associated with tuberculosi—but apparently bacillary. The patches react, however, in a characteristic manner to injections of tuberculin.

BRITISH SANATORIA FOR CONSUMPTION.—VIII.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

THE WHITEMILL HILL SANATORIUM.

The highlands of Surrey have long been famous for their varied beauty, unspoilt natural wildness, delightful climatic conditions, and convenience of access to London. The glorious district lying around the Hog’s Back and reaching southwards to Midhurst and the Hampshire Downs, eastwards to Box Hill and Leith Hill, and westwards to the open country around Farnham, forms an almost ideal sanatorium for the great Metropolis less than forty miles away and within easy railway or motor journey.

The Whitemill Hill Sanatorium is admirably situated in this peculiarly attractive and eminently suitable neighbourhood. It is about three and a half miles from Farnham, and is but a short drive through the picturesque little hamlet of Tilford. It is most excellently placed for its purpose.
To the south a wide expanse of landscape lies stretching away on the east from Leith Hill and the Chartthouse to the Hampshire hills on the south-west, with the heights of Hindhead presenting immediately south, with extensive tracts of open, heather-covered common land and undulating pine-clad country. On the north protection is afforded by Crooksbury Hill and its ridges, rich in their thick covering of pines, and now heather in gorgeous bloom. The district affords endless opportunity for health-giving rambles, and the nineteen acres of the estate connected with the Sanatorium, with its gardens, lawns, fir woods, and well-constructed paths, supplies almost inexhaustible opportunities for the pleasurable out-door life of the patients. The numerous walks have been arranged with much care, and allow of careful gradation of walking exercise. Seats, kiosks and convenient revolving shelters are placed in different parts of the grounds. We found also that at least one patient was enjoying a return to the primitive luxuries of tent life.

THE WHITMEAD HILL SANATORIUM.

The house is well adapted for its purpose. The original portion, now a little more than four and a half years old, was constructed to afford the comforts and delights of an ideal country residence, and the charms of home life fortunately still linger and go far to take away the institutional atmosphere so usually associated with sanatoria. The new west wing has been added to meet the best requirements of modern hygienic treatment, and affords accommodation for twelve patients. This portion of the sanatorium is excellently arranged. Although each room is small, the comfort and well-being of the patient are well provided for. Each room is well ventilated, has wide and large windows opening on to a balcony on the upper storey, and on to a verandah on the lower, with fire-place, electric light, and all necessaries.

The verandah, which, of course, is open to the south, is particularly capacious, being 63 ft. by 15 ft., thus enabling patients to enjoy what is practically an open-air life irrespective of weather.

The corridors are light, airy, and can be heated by hot-water coils.

Conveniently arranged baths allow of the employment of hydro-therapeutic measures. The water is of good quality, and is drawn from a private well. The sanitary arrangements appear to be well organised and thoroughly attended to.

The Sanatorium may well take a foremost place among the small private institutions specially designed and definitely conducted for the rationally directed treatment of consumptive cases arising in the well-to-do classes. Dr. J. Hurd-Wood is the proprietor and resident physician, and from an exceptionally wide and lengthy medical experience is peculiarly fitted for the conduct of such an establishment. Treatment is carried out under the personal supervision of Dr. Hurd-Wood, who takes his meals with the patients and directs every detail of their daily routine. The nursing is under the care of a fully-trained and well-qualified sister.

As far as we could gather, treatment is conducted in strict accordance with the best hygienic principles, free from meddlesome fads and on sound rational lines. Forced feeding is not insisted on, but much care is given to the regular, well-selected and carefully directed dietetics. We have carefully studied the rules and directions given to each patient, and find them based on sound principles and evidently the outcome of much clinical experience.

The fees, five guineas, are inclusive, the only extras being personal washing, alcoholic liquors, and bedroom fires, which are only allowed at the discretion of the doctor. Extra payment is, of course, required when spinal nursing is needed.

Whitmead Sanatorium is best reached from Farnham station (S.W.R.), where cabs may always be obtained. Telegrams should be sent to Tilford.

FRANCE.

PARIS, August 18th, 1903.

PLACENTAR OPOTHERAPY.

Dr. Bonnacourt, having remarked that the placenta of the sheep provoked a stimulating and congestive action on the mammary gland of woman, his colleague, M. Vivie, instituted a series of experiments with a view of studying the value as a galactagogue of the placenta administered internally.

The placenta utilized was that of the sow, on account of its large volume, and also because that animal was generally exempt from disease. After washing the organ in sterilized water, he cut it up and macerated it for twelve hours in pure glycerine. The liquid was then filtered and distributed in bottles.

The decidual juice thus obtained was given at the dose of from two to six teaspoonsfuls a day in cold water, each dose corresponding to fifteen grains of the fresh placenta.

Under the influence of that treatment, nurses in whom the milk flow was insufficient remarked that the secretion increased rapidly, while no ill effects were experienced from the ingestion of the mixture.

SUPPURATIVE TONSILLITIS.

As regards the treatment of the above painful affection, Trousseau was accustomed to say that no earthly treatment, such as rebusives, astringents, &c., succeeded in arresting its development or cutting it short; it ran its course in spite of all up to the ninth day, when the abscess burst, putting an end to the suffering of the patient. It must be admitted that the assertion of the great professor has been found correct by every practitioner. However, within the last two years a drug which seems to be particularly active in several affections, furunculosis, pneumonia, chronic bronchitis, eczema, &c., has been employed in suppurative tonsillitis and, if reports are to be believed, will be of great benefit to the unfortunate patients.

Beer yeast in the treatment of that affection has been chosen as the subject of his thesis by Dr. Ferry. According to him, the yeast suppresses very rapidly (in a few hours) the intense pain of deglutition. It suppresses also the lancinating pains which the patients complain of in the ear. In one or two days the patient is well enough to resume his occupation. The tonsil will remain swollen for a few days, but it will not be painful. Another advantage derived from the yeast treatment is the almost absolute certainty of preventing complications such as suppuration of the corresponding tonsil (so frequently observed), oedema of the glottis, septic infection, ulceration of the arteries, &c.
THE OPERATING THEATRES.

The benefit derived from the administration of salicylate of soda in the treatment of Basedow's malady is being continually corroborated by practitioners in France. M. Chibié, who recommended this treatment, reported lately four cases very amenable to the drug. He prescribed one dram daily in Vichy water. The improvement was very rapid. M. Babinsky communicated to the Société de Neurology at Paris, three cases of which two were accompanied with intense tachycardia, 120 to 140 pulsations. After a few months of the salicylate treatment, the patients fell to eighty and the trembling disappeared. In the third case, where the only symptom was goitre, the gland entirely disappeared at the end of three months. No other treatment was employed in any of these cases.

Austria.

[FROM OUR OWN CORRESPONDENT.]

— VIENNA, AUGUST 21st, 1893.

Pathological Anatomy of Morbus Addisoni.

At the last meeting of the Gesellschaft für Innere Medizin, Wiesel gave a longhistory of the pathology of morbus Addisoni, and dealt at length with what he described as the latest results of the pathology of the disease in the sympathetic nervous system and the suprarenal bodies. In the sympathetic nervous system, he affirmed, we had more than fibres and ganglionic cells, as there was a third very important factor in its constitution—viz., the "chromaffin" cells, which were found in the form of small tubercles or bodies throughout the sympathetic system. These cells were identical with those found in the parenchymatous substance of suprarenal bodies, which were now acknowledged as the active physiological factor in the production of movement in non-striated muscles. A second element was an accessory suprarenal body.

In five cases of morbus Addisoni he showed the total absence of the chromaffin cells, while the suprarenal bodies appeared to be quite intact. On the other hand, he showed cases with a converse condition, and concluded that in Addison's disease the chromaffin system was the primary morbid centre of disease, whether confined to the centre or periphery of the gland. The secondary changes were found in the sympathetic nervous system. The destruction of the function of the chromaffin cells produces the clinical symptom of asthenia and adynamia. Wiesel thought this chromaffin theory elucidated all the cases brought forward by Addison.

Schröter said he had often seen cases of healthy men with pigmentation of the mucous membrane of the mouth, although no other symptom of disease could be observed. Ehrmann remarked that pigmentation of the mucous membrane of the mouth was not a pathological condition, as many people with summer freckles had similar pigmentation. In morbus Addisoni it was abnormal, occurring all over the body in opposition to chloroma uterus as white patches. In the head the pigmentation appears at the cell of the hair instead of the epidermal covering. It is doubtful if this hyper-pigmentation is due to a toxic agent, although arsenical melanosis is quoted as an example, but he would like to know what connection the function of the sympathetic had with the pigmentation in morbus Addisoni, and if the chromaffin cells were secretory bodies affected by poisons so that they produce pigmentary cells.

Wiesel replied that close examination of all the cases under his care revealed no trace of a chronic toxic action. Possibly these chromaffin cells lay in the walls of the vessels and were closely connected with the direct formation of the pigment.

Ehrmann said that in his examinations he had found the walls of the vessels so much damaged that hemorrhage was the result of these pigmentary patches.

The Operating Theatres.

WEST LONDON HOSPITAL.

Three Cases of Fractured Patella Treated by Wiring.—Case I.—Mr Swinford Edwards operated on a man, aged 20, who had re-fractured his patella; the first fracture had been treated by wiring at another Metropolitan hospital. The present fracture had occurred two months after the operation and was the outcome of indirect violence. An X-ray examination showed that the wire which had transfixd the upper and lower fragments had come untwisted at the upper border of the upper fragment. The fragments were separated by about half an inch, and the wire was clearly seen passing between them. The first operation had been performed through a lateral flap on the inner side. The patient was operated on for the second time a week after admission to the hospital. Mr. Edwards made an external lateral flap, turned out the blood clots, removed the wire, and re-drilled each fragment in a longitudinal direction on each side of the site of the original drilling. The lower fragment was found to be very small, so that he used a thinner wire than usual. On twisting up the wires the fragments came into capital apposition. The flap was sutured, the wound dressed, and the limb placed on a back splint.

Case II.—The patient was a woman, aged 20, who had sustained a transverse fracture of the patella through indirect violence. The operation took place a week after the date of the accident. The knee-joint was exposed by an external semi-unar flap, all blood clots cleared out, and the inverted aponeurosis lying between the fractured surfaces was removed. The upper and lower fragments were drilled longitudinally in the mid-line, and the bones brought into apposition with one strand of strong silver wire which was tightly twisted up, the superfuous wire cut off and the twisted portions hammered down into the tissues just above the patella. Deep silk sutures were now used to bring the aponeurosis together over the strand of wire passing in front of the patella, the joint having been carefully irrigated with a 1 in 2,000 sublimatic solution. The wound was closed and dressed in the ordinary manner and a back splint applied.

Case III.—The patient was a bus-driver, aged 34, who had sustained a fracture of his right patella through direct violence. A week after the accident, on exposing the joint by an external lateral incision, it was found that the ligamentum patellae was torn from its attachment to the patella, carrying with it only a small spicule of bone, hardly to be called a fragment. The patella itself had sustained a longitudinal fracture, but the fragments were, of course, in good apposition. This injury evidently resolved itself into a case of ruptured ligamentum patellae. Each half of the patella was bored longitudinally, and a medium-sized wire passed through one half and then threaded by needle and made to transfix the ligamentum patellae through the middle of its substance from side to side. The end of the wire which had just passed through the ligament was now passed through the bore or tunnel in the other half of the patella and twisted up with the other end at the superior border of the patella. The rest of the operation was carried out as in the previous cases.
Mr. Edwards remarked that the above cases were good examples of the difference in the direction of the fracture in direct and indirect violence. In the first and third cases he said that it would be necessary to keep the limb on a back splint—that is to say, at rest—for a fortnight; whereas, in an uncomplicated case of transverse fracture of the patella such as the second, he made a practice of removing the back splint at the end of the first week, passive movement being carried on for the following week. As far as he was able to judge, he remarked, in the first case no blame could be attached to the original operator, the patient having had the misfortune to meet with a second accident. Mr. Edwards said he was in the habit of treating all cases of transverse fracture of the patella by silver wire suture, and of the various methods in vogue he thought the one employed in these cases was by far the most satisfactory, not only as regards the skin incision, but also in the method of inserting the wire. He pointed out that the external lateral skin flap is out of the way, and is not liable to damage when the patient kneels as would be the case with a longitudinal or transverse incision. Besides this, it affords every facility for drainage, should this be necessary. With regard to the way of inserting the wire, he thought that by the method he had employed the fragments were kept in accurate apposition, which, he considered, is not so securely done by the ring or purse-string suture round the patella, which both have a tendency to make the fragments bulge, and, furthermore, they have the disadvantage of leaving a foreign body in the joint.

The Medical Press and Circular.

The publication of the first Report of that body marks an era in the organised investigation of what has hitherto been one of the most mysterious scourges of mankind. The first Report of the Fund is, naturally enough, of interest as the harbinger of future achievements rather than of present results. The term “cancer” has been taken to include all the malignant new growths, both of man and of the lower animals, so that the field of investigation is sufficiently comprehensive to include all varieties and degrees of malignancy, as well as the possibility of transmission between mankind and some lower forms of animal life. The comparative study of malignant new growths opens up a field of great promise. The Report states that out of a great number of specimens submitted for examination a great many were excluded as infective morbid conditions, while thirty-one cases of malignant new growths were met with in the dog, horse, cow, sheep, and mouse. Specially interesting were a series of true epitheliomata from the horse, cow and dog; and, in addition, some specimens from the dog presenting the histological appearances characteristic of rodent ulcer in man. The question of electro-therapeutic measures in the treatment of malignant growths has naturally received much attention. For the present this particular point is wisely regarded as being sub judice. At the same time the Report endorses the general consensus of opinion to the effect that many superficial rodent ulcers, even if very extensive and of long standing, can be made to heal completely by means of “the X-rays alone.”

Safer statement, by the way, would have been that such results are obtained by exposure to an active focus-tube, as it seems more than probable that the X-rays themselves exert no therapeutic action. Nor, in our opinion, does the Report recognise to its full extent the undoubted influence of the focus-tube upon surface epitheliomata. The whole question, otherwise, is still in its embryo stages, although it may well be believed that the three agencies of light, X-ray tube, and high frequency current will play an important part in the future treatment of malignant growths. The question of the statistics of cancer is discussed generally. The mass of information available, both from purely statistical and from purely pathological statistics, is enormous. The application of more accurate methods will doubtless lead to the formation of general conclusions of value. One point of the greatest interest is mentioned—namely, the relatively smaller number of cases of fatal cancer recorded in Ireland as compared with the rest of the United Kingdom. Altogether, the appearance of the Report under notice constitutes a notable landmark in the apportioning of the heritage of the medical world. It marks an organisation which embraces energy from social as well as scientific quarters, and possesses an incalculable amount of potential energy. We note that in some quarters the possible or probable disposition of the funds has been sharply criticised. So far as regards the great medical bodies directly or indirectly concerned, the public may rest assured
that monetary matters will be administered in accordance with the traditions of an honourable profession.

THE POLLUTION OF OYSTERS.

The causes of the very real perils which beset the consumption of oysters from the Emsworth beds, resulting in the serious outbreak of enteric fever consequent upon the mayoral banquets at Winchester and Southampton on November 10th of last year, have now been fully investigated. From the report of Dr. H. T. Bulstrode upon the subject to the Local Government Board there is no room for doubt that the molluscs in question were directly and solely responsible for the epidemics, not only of typhoid but also of various types of gastro-enteritis. Of the Winchester cases, ten were found to be true enteric out of a total of 134 guests, and of the 133 guests at Southampton, eleven were attacked with the disease; five deaths unfortunately occurred. By obtaining a direct census of the articles of diet partaken of by each person at the dinners it was ascertained that every individual who was afterwards affected with typhoid had eaten oysters. A careful examination of the other articles of food, including the milk-supply, and an investigation into the sanitary condition both of the places where the banquets were provided and the homes of the patients themselves, were alike entirely negative. Moreover, an important fact remained in that other epidemics of enteric fever were occurring at other places supplied with the Emsworth oysters at the same time. The chain of evidence may therefore be said to have been complete. As long ago as 1895 the danger attendant upon the storage of oysters in the Emsworth pits was pointed out by Dr. Bulstrode in a valuable special report, so that the public was not without due warning. That these pits were actually specifically contaminated prior to the outbreaks was proved by the fact that the main sewage of Emsworth discharges practically over them, and in October and November last year there were nine cases of typhoid in the town. It was found that the drainage of eight of the houses led into the sewer in question! When the storage pits are situated in shallow water they are apt to become uncovered at low tide, with the consequence that if there be any sewage discharging in their immediate neighbourhood they are more or less fouled. If the oysters be gathered at such a time they will be in a greater danger of contamination than when the sewage is well diluted. The whole position of oyster pollution is unsatisfactory from the public health aspect; for, apart from the threatened danger to the industry and the general and almost unavoidable exclusion of a useful article of food, there is, as yet, no legislative inquiry specially directed into this matter in progress. The Royal Commission on Sewage Disposal dealt, of course, primarily with the main object for which it was instituted; but it would surely be a national advantage if a section of it could be brought to consider more particularly that view of the question affecting the distribution and prevention of contamination of the various oyster beds scattered along our coasts. Owing to the custom of some dealers of storing oysters temporarily in pits near the foreshore of the town in which they live or in which it is desired to sell them, suspicion will not only rest upon those known to be taken from infected localities, but also upon those which are deposited therein for a time and brought from a distant but uncontaminated spot. The matter, therefore, is more serious than it appears at first sight, for if the beds at Emsworth be employed for this purpose, as they are said to have been, the reputation of hitherto unimpeachable firms will be endangered. It is to be hoped that Dr. Bulstrode's report may awaken the interest which it fully deserves. In view of the widespread alarm which has arisen in many quarters owing to the dangers of consuming oysters which may have been specifically contaminated with typhoid, lovers of the delectable bivalve will be glad to hear that the Fishmongers' Company has taken up the matter officially. The various beds around the coast have been inspected, and the oysters taken therefrom submitted to bacteriological analysis, with the result that many of them have been closed. The Company, in a recently issued circular, pledges itself to ensure that, as far as it is enabled, none but healthy oysters from beds of known purity shall be placed on the market, and it invites the assistance of medical and sanitary authorities in reporting defects in drainage, &c., which threaten to be sources of contamination. By this action it is hoped that the public confidence may be restored, and the position of the trade improved.

QUACKS AND QUACKERY.

One of the most pressing reforms of to-day is the suppression of quackery. It is practised under so many different forms, and so universal has it become, that no class of the community can escape the evil. That it does incalculable mischief all acknowledge; but it is so profitable that it enlists thousands in its pursuit, all of whom vehemently resist any interference with what they call "the liberty of the subject"; but which is nothing less than a licence to make money by fraudulent means, to the injury of the public, both in pocket and health. We regret to say that not infrequently men qualified and eligible to carry on an honourable trade deliberately embrace the "profession" of quackery. In such a position is the prescribing pharmaceutical chemist when he, as is not uncommon, keeps his "consulting room" and has his "at home" hours. He becomes as imitative as a monkey; his writing desk is furnished with the most recent forms of binaural stethoscope, a hypodermic syringe, and a urinary testing apparatus. In such a room, after being medically examined and prescribed for the quack, how is a poor uneducated person to know that the L.P.S.I. is not a medical qualification? All the surroundings are those of a medical study, and intentionally so. They are arranged by the quack to aid him in impressing on his "patient" that he possesses a knowledge of disease acquired.
in a medical school. This fraud is carried out by those who know that the Pharmaceutical Act expressly excludes medical subjects from the pharmaceutical chemist’s qualifying examination. From one of these consulting rooms a man with a strangulated hernia left with a prescription for bicarbonate of soda and hydrocyanic acid. The time occupied in taking the eight-ounce mixture was fatal. In another case a thoracic aneurysm was vigorously treated by one of the quacks, who was exonerated by a coroner’s jury because he did what he considered best, the fact that he had no right to treat the case at all being wholly lost sight of.

We are glad to note that at the recent conference of the British Pharmaceutical Society the President expressed the belief that a separation was proceeding between pharmacy and medicine, and he stated that in the interests of medical men, pharmacists, and the public such separation should be hastened. We fear, however, that there is a certain amount of optimism in his pious belief that ‘‘chemists prescribe much less commonly than formerly,’’ but we cordially re-echo his hope that they would give it all up together. For our part, although we wish that it were possible for all medical men to give up the compounding and dispensing of medicines, we cannot regard the position of those who find it necessary to continue to dispense as at all analogous to the position of the pharmaceutical chemist who deliberately infringes the law by prescribing. The former undertakes a responsibility which he is capable of discharging and entitled to discharge, whereas the latter assumes a responsibility which he is incapable of discharging, and which is only rendered possible and profitable by the credulity of the public.

Notes on Current Topics.

The Perils of Tube Railways.

Each phase of human progress brings with it special and unsuspected risks. The discovery of coal gas as a source of illumination transferred to our homes risks of explosion previously familiar to us as one of the amenities of mining. The introduction of underground railways placed partial asphyxia within the reach of the humblest, and the employment of powerful electric currents has made death by artificial lighting a tolerably frequent occurrence; while an entirely new class of fire risks have been created, far more terrible in their incidence than the old-fashioned gas explosion. In the tube railway, the latest development of transport enterprise, these two risks are associated and are reinforced by peculiar and terrible risk of certain death by asphyxia should short-circuiting take place, a not unlikely contingency, escape being rendered quasi-impossible by the absence of any provision for the passage of the scared passengers along the tube and the imminent risk of their coming into contact with the live rail which lies ready to inflict sudden death on the hapless traveller in a darkness which is one of the invariable sequelæ of accidents of this kind. The fact is that engineers have transferred to the construction of tube railways apparatus and appliances which had been found to work well above ground, apparently without giving the special circumstances a thought. Recent events have given rise to such a feeling of insecurity among the public that in their own interests the managers of these underground railways will do well to remedy the more obvious shortcomings with the least possible delay. Foremost among them is a means of preventing the spread of fire from the motor apparatus to the carriages, and, secondly, the employment of non-inflammable materials for carriage construction. In order to facilitate escape in the event of a mishap the live rail ought to be placed somewhere out of easy reach, and with the same object in view a source of light should be available independently of the working current. Neither gas nor oil lamps would answer the purpose, because they are too sensitive to the influence of foul air, and the only trustworthy plan is probably a system of electric lights, in circuit with accumulators, so that fusion of the wires at one part of the tunnel need not entail extinction of the light throughout. Until the necessary improvements have been made we shall feel that each time we take a ticket we are deliberately incurring risk of life, a mental state which will assuredly be reflected in the dividends. The subject, however, is of such sinister importance that we are justified in looking to the Government to protect us against such risks as can be foreseen, and the risk of fire with immediate asphyxia is one which had occurred to many.

Adrenalin.

It is not so long since therapeutists pointed with pride to the elimination of animal products from the pharmacopeia. We had musk, lard, cod-liver oil—the former was seldom used, and the lard was being displaced by petroleum products. We were supposed to have reached the apotheosis of therapy, when presto! we learned the value of thyroid extract, and at once every tissue and organ in the body was laid under tribute. MM. Bra, Paul, Ewald, Bruns, and Bramwell, with others, advocated the use of the animal products, following the teaching of M. Brown-Sequard. Manufacturing chemists took advantage of the fashion in medicine, and we had extracts prepared from the testicle, the ovary, the grey substance of the brain, the thyroid, the cardiac muscle, the pancreas, the liver, the suprarenal capsule, the kidney, the lung, and so forth. Scarcely a decade has passed since these products were introduced, and of the list the thyroid extract and the suprarenal have not alone been retained in practice, but have gained in favour. Indeed, adrenalin has become so generally used that we are apt to forget that it was unknown until January, 1901, when J. Takamine, the distinguished Japanese chemist, isolated it from the suprarenal substance, and completed a series of investigations into the physiological action of the gland substance that had been commenced, though crudely, by Montesquieu, in 1716, who read his report to the
Academy of Science, Bordeaux, in the same year. Bichat, Hein, and Neumann took up the task, and had to acknowledge each in turn that his labour was fruitless. In 1855 Addison made his memorable discovery, and in the year following M. Brown-Sequard announced that the gland produced a secretion, and there was a hope of our coming to a knowledge of the gland and its structure, when, unfortunately, Bergmann started his nerve theory, which held the field until d’Abeulose and Langlois upset it in 1886. The suprarenal secretion discovered by d’Albanese (1892) and Bonich (1894-96) was said by Guarneri and Marino-Zucco to contain a phosphoglycinate of nerve. Mühlman, however, considered that it was a salt of pyrocatechin (C₉H₆O₅). The reactions of the product justified the chemist in his conclusions, though the physiological tests demonstrated a marked difference in the substances. A further advance of our knowledge of the substance was made by the discovery of suprarenaline by Abel and Crawford; and so matters were until Dr. J. Iakamine undertook the study and pursued it so successfully that the drug has become universally used. But of the therapeutics of the drug adrenaline we have yet much to learn, for although many interesting physiological experiments have been performed the results are often contradictory.

The Barmaid Question.

For long much discussion has proceeded regarding the disadvantages of employing females in public drinking-bars. The barmaid has for long been a familiar, and it must be admitted, not uncommonly a particularly attractive, feature of many English licensed resorts. In some countries the employment of females in connection with the sale of alcoholics is prohibited by law and discouraged by custom. Recent events have done much to force this question to the front. We have here only to deal with the hygienic aspects of the case. From the standpoint of personal and public health there can be no doubt the employment of women in drinking-bars is altogether a mistake. On psychological as well as physical grounds the practice may well be condemned, and in the interests of the seller as well as for the protection of the customer, the employment of unmarried females may well be rendered illegal. The life of the average barmaid is necessarily unhealthy for both mind and body, many lapse into habits of intemperance, and from the conditions of the work morbid psychical and abnormal physical states are readily induced. Speaking purely from the medical standpoint, there can be no hesitation in declaring that the State should protect itself by safeguarding its women from such dangerous conditions of life as are at present inseparable from the majority of drinking-bars.

The Blighting of Babies.

Pessimistic views predominate in many quarters respecting the development of the young life of the nation. With a falling death-rate there is certainly a falling birth-rate, and according to apparently trustworthy authorities the infantile mortality does not bear any proper proportion to the general mortality decline. The President of the British Medical Association at the recent Swansea meeting declared that “the rate of general mortality had decreased in the last thirty-six years, but, on the other hand, the mortality of children had increased.” The reports of medical officers in various parts of the country express a similar opinion. There is, indeed, only too clear evidence that the blasting of infant life is enormous. Much of the mortality during the first years of life is manifestly preventible. But it seems desirable that careful investigation should be made as to whether we are retrograding in the protection of baby-life, as some statisticians would have us believe. Undoubtedly much has been accomplished for the betterment of mothers and the safeguarding of childhood, and there is reason to think that, rightly interpreted, the outlook is not so dark as melancholy souls would believe. And yet the prospect is undoubtedly serious. The spread of inebriety among women, the distaste for duties of motherhood, the increasing struggle for existence at one end of the social scale and the growing love of luxury at the other, all tend to jeopardise the young life of the nation. Much evidence has also been recently produced to show that vast numbers of young children suffer from malnutrition directly dependent on neglect, and on all hands signs of arrested growth and maldevelopment are only too clear to the seeing eye. And yet, in spite of discouragements, which indeed are manifold, there is much need for the suppression of the pessimist, and every reason for the development of a practical optimism.

The Thames as a Sanatorium.

On some hot and depressing August day, when London streets burn and blister, and when the longing for the open country becomes almost unendurable, no thinking stroller along the Embankment but must be impressed with the advantages of the Thames to the Metropolitan toiler. The great river might well become a veritable sanatorium for the City worker. The rich can well reach their house-boats in the upper reaches, where aquatic life can be made luxurious with all the fastidiousness of latest fads and most recent fashions; but for the poor Father Thames still remains a distant relation. Enormous sums of money are being expended, and very rightly so, in the opening-up and laying-out of our public parks, and much thought and ingenuity is bestowed on the elaboration of means for conveying the labourer into the country; but few voices are raised in praise of the hygienic advantages of the silent riverway. It is much to be regretted that no means can be found whereby the Thames can be used as “an open space.” We hear much of garden roofs and garden cities, city playgrounds, and the like; but in our eagerness to provide such it would be well if we could develop the potentialities of Father Thames as a sanatorium.
Typhoid Fever in South Africa.

The recently issued report of the Commission instituted by Mr. Brodrick in 1900 to inquire into the nature, pathology, causation, and prevention of dysentery and its relationship to enteric fever, shows that, at least as far as the origin of the two diseases is concerned, they have much in common. They are both essentially filth-diseases, but according to Colonel Notter, there cannot be said to be any one specific insanitary condition which accounted for their prevalence during the late South African campaign. Many are the contributing factors which led to the incidence of typhoid fever among the troops, such as the fouling of water and soil, the insufficiency of the arrangements for scavenging, the preponderance of young men in the ranks, and the exhausting nature of the work which they had to perform. Stress is also laid upon the malign influence of flies as carriers of pathogenic germs, and also on the effects of dust in contaminating food and water. Actual decomposition of food appears to have more connection with dysentery than enteric fever. Professor Simpson’s report upon the cost of typhoid presents an appalling illustration of the enormous expense which is involved, not to mention the far more important loss of valuable lives, when preventive measures are inadequate or neglected. Thus, the estimated cost of this disease alone is placed at between three and four million of money, and 6,000 lives. This is, indeed, an object lesson which cannot fail to impress itself indelibly upon the minds of sanitary reformers and military authorities alike. As Colonel Notter rightly insists, it is the organised system of scavenging work which is “practically the pivot on which the whole question of camp sanitation turns,” and this is the chief preventive measure to which attention was least paid, with the results which are now known to all. The practical difficulties naturally attendant in connection with matters of military reform are great, but the suggestion with regard to the formation of a scavenging corps is good, and one which should prove of material assistance in rendering the camps less like the hotbeds of disease which they have hitherto been.

The Mosquito Plant.

Dissillusionment is seldom agreeable, especially when our most cherished beliefs are shown to be lacking in solid foundation, but when the virtue of a remedy from which great things were expected is at stake, keen is the disappointment which is felt when it is “weighed in the balance and found wanting.” The scales of public opinion are poised very truly, but the balance of science is hung with even greater accuracy. The supposed “anti-mosquito” properties of the Ocimum viride, or Holy Basil, discovered by Captain Larymore, R.A., of Northern Nigeria, and afterwards confirmed by Sir George Birdwood as a result of his experience in Bombay, are, it is feared, incapable of practical application as a prophylactic remedy. Dr. Prout, medical officer to the Colony of Sierra Leone, has undertaken an investigation into the alleged properties of the plant in question, and he found that the insects live and thrive when kept in close proximity to the basil in the same manner as they do with any other plant. Some deleterious effects are produced upon mosquitoes when the leaves are burnt, so that in this way the plant may be found useful. The inutility of the freshly-growing Ocimum as a means of warding off the approach of the insects is also confirmed by Sir William Thesleton-Dyer, the Director of Kew Gardens, who states that the experiments conducted by Dr. Prout indicate clearly that there is no protective value afforded by the plant. On the other hand, the fragrance derived from a bank or hedge of basil is said to be most refreshing. It is, of course, possible that the altered conditions of soil and methods of planting and draining which were adopted in the Victoria Gardens at Bombay may have rendered the mosquitoes more liable to the influence exerted by the plant of which Sir George Birdwood speaks so highly. The efficacy, however, of the basil as a protective against mosquito-borne malaria may hardly be said as yet to be sufficiently proved.

Prolonged Gestation in Anencephalia.

It has been noted that gestation is often prolonged far beyond the normal period in cases of anencephalic fetus; in fact, out of four cases of the kind observed by Drs. Bender and Leri, in two the pregnancy lasted ten and ten and a half months respectively. This fact is interesting because it is suggested that the prolongation of the period of gestation may be due to the absence of a head of sufficient volume to stimulate the lower segment of the uterus to contraction. Possibly this may assist us in arriving at an explanation of the mechanism by which gestation is automatically brought to an end.

Opium in Infantile Carditis.

In the heart affections of childhood two facts stand out prominently which serve to distinguish them from morbus cordis in the adult. In the first place, the inflammation of the heart in the child is in reality a more or less general carditis, as was pointed out by the late Dr. Sturges, the endocardium, the myocardium, and the pericardium being involved together. Secondly, the effect of the nervous system upon the child’s heart has been shown to be considerably more powerful than in the adult. Dr. Alexander Morison, in the course of a paper read before the provincial meeting of the Society for the Study of Diseases in Children, for these reasons emphasised the undesirability of applying leeches to the precardium in children on account of the emotional excitement thereby produced. He also condemns the use of digitalis as being incapable of procuring sufficient rest for the organ. Instead, he would advocate the judicious exhibition of opium, than which there is no drug more potent in its soothing influences. The fear of pre-
scribing this remedy to children, shared by the majority of practitioners, is doubtless responsible for its non-employment in heart disease at this period of life. Dr. Morison finds that even in young infants there is a greater tolerance shown towards opium when the heart is affected than when it is in a normal condition, and he cites several instances in which the drug had produced a most beneficial effect. Autopsies in cases of infantile morbus cordis frequently reveal the presence of healthy cardiac muscle, while the pericardium is severely affected, which fact should lead us to suppose that the inflammatory reaction may be calmed and the cardiac mechanism restored through the agency of the nervous system rather than by the application of more direct means. Idiosyncrasy must, of course, be watched for; but, if the nervous control can be suitably regulated by opium, we possess a remedy for the heart affections of childhood which has certainly been hitherto neglected.

**Syphilis in the Anthropoid Ape.**

There are a number of moot questions in the pathology of syphilis which have remained unsettled simply because the ethics of experimental observation forbid the utilisation of human subjects for such a purpose. Moreover, observations on some very essential points when made on human beings are subject to what we may call the personal equation of truth on the part of the subject, thus vitiating the results obtained. Attempts to inoculate animals with syphilis have, for the most part, proved futile, and even in certain successful cases the evolution of the disease was so different from that in the human being that no trustworthy conclusions could be based thereon. Professor Metchnikoff has recently succeeded in inoculating female chimpanzees with the virus, and we are justified in hoping for additions to our knowledge in this interesting department of pathology in the near future. At the Academy of Medicine no doubt was expressed as to the genuineness of the infection, although the time had not yet arrived for the characteristic secondary symptoms to make their appearance.

**The Small-pox Epidemic.**

Reports of the occurrence of fresh cases of small-pox continue to be received from the provinces. In Lancashire the outbreak is showing signs of diminishing, and an important step has been taken by the Public Health Committee of the County Council in recommending that primary vaccination and re-vaccination should be rendered compulsory. The epidemic at Cambridge of over one hundred and twenty cases during the last two months has caused some alarm in that town, but, happily, it is at last being got under control. In both localities the case is very strong for vaccination, the mortality among the unvaccinated being much greater than among the vaccinated. The obvious lesson to be derived from this is that, unless the British nation desires to remain behind other nations of the civilised world in matters of public health, vaccination and re-vaccination must be made compulsory by law. It is not until the "conscientious objection," or, as a contemporary somewhat forcibly puts it, "imbecility," is altogether abolished that we can hope to attain to the immunity from the disease enjoyed by Germany, where small-pox is almost unknown. Such a time cannot be far distant, for the herald of compulsion has already sounded its warning but beneficent blast.

**Maternal Ignorance and Infant Feeding.**

*Nature* has taken the surest way of securing a safe and sufficient milk supply for each new life. But in the course of so-called civilisation, the functions of maternity and the fulfilment of milk secretion are oftentimes dissociated, and, either from wilful neglect or unavoidable necessity, human milk has to be replaced by a bovine secretion. Cow's milk is peculiarly liable to contamination, and almost criminal ignorance prevails regarding measures to ensure its due protection. Most mothers are profoundly ignorant as to the principles which should guide them in the selection and preparation of their children's food. We are glad to see that the Tottenham District Council has decided to appoint a lady inspector whose chief duty will be to instruct mothers in the care and feeding of young children. We would suggest, however, that it would be more reasonable to commence instruction at a somewhat earlier date. Every girl, we contend, should be trained in the practical duties of domestic life during school days, and instruction in the management of babies should not be left to the haphazard opportunities for experiment offered by the coming of the firstborn. For this form of vivisection we have no sympathy.

**The Bicarbonate of Soda Treatment of Varicose Ulcers.**

It is not open to every sufferer from varicose ulcers of the legs to experiment with the oxygen treatment, and, as the lesion is exceedingly common, it may be worth while calling attention to the excellent results obtained by dressing these ulcers with compresses steeped in a solution of bicarbonate of soda containing from 2 to 4 per cent. of the salt. The suppuration is stated to diminish forthwith, and healing proceeds apace. It is a simple means of dealing with a very troublesome class of cases, and the results are promising.

**Psychology and the Post Office.**

The forty-ninth annual report of the Postmaster-General just issued not only affords a remarkable record of State socialism, but also presents matter rich in suggestiveness for the psychologist. For instance, twenty-five millions of letters and parcels could not be delivered because the addresses written by the senders on the covers were either incorrect or insufficient, or because no address at all was given. The carelessness of the average individual is prodigious, but, unfortunately, it is not limited to dealing with the Post Office authorities, but is apparent
in almost all matters pertaining to hygiene. Ignorance is accountable for much, but wilful carelessness is accountable for more. The happy-go-lucky life of the average hospital patient would be pathetic if it were not so peculiarly irritating to the painstaking physician. And this neglect for care of self and absence of thought for others stand at the etiological foundation of much of the disease and disorder which disturb the peace of the moral world and derange the pleasures of physical existence.

**Bathing Fatalities.**

The holiday season brings sadness and disaster to many a household. At this season of the year the daily papers in almost every issue contain a heavy list of bathing fatalities. Deaths from drowning occur with alarming frequency and in most cases under conditions which a little forethought and careful arrangement would have robbed of much of their danger. We are strongly of opinion that greater attention should be devoted to the training of all children in the art of swimming, but we are also certain that the authorities of many health resorts grievously fail to maintain adequate provision for the safeguarding of the lives of their visitors. At all bathing stations protective measures should be provided. Often times the only prophylactic effort is expended in the erection of comparatively useless notices. A holiday resort which spends much in advertising its many excellencies should not be miserly in the protection of the lives of those who now, in seeking health, too often frequently win death.

**Lavatories and Looomotion.**

At this time of the year, when long distances are undertaken for purposes of pleasure or the interests of health, and when corridor trains become the meeting place for all sorts and conditions of men and women, and oftentimes are really travelling hospitals, it is very necessary that attention should be drawn to the necessity for maintaining strict supervision over lavatories and retiring compartments. On certain lines the arrangements are very primitive, and in not a few instances the closets are so ill-designed and badly served that they offer opportunities for the dissemination of disease as well as the continuance of much discomfort to the users. Medical officers of health might well direct their attention to the too much neglected subject of railway sanitation.

**The Health of School Children.**

The very comprehensive report of the Medical Officer of the London School Board (Dr. Kerr), recently issued, provides much that is interesting and important in connection with the physical condition of school children. In the first place the necessity for obtaining more systematic measurements is pointed out with the object of ascertaining the degree of improvement apparent after going through the courses of physical drill and exercises. In connection with the latter, a caution is given with regard to the danger of over-fatigue, especially in the case of the younger children. It is satisfactory to note that during the past year there has been no outbreak of infectious disease of any magnitude. The appointment of visiting nurses for the purpose of inculcating the principles of cleanliness among parents is a step in the right direction, though it is hardly, perhaps, altogether desirable that the diagnosis of such a disease as ringworm of the scalp should be undertaken by a nurse, however experienced she may be. The most that she should attempt is simply the isolation of any case that appears suspicious for further confirmation or rejection by the medical officer, who, by preference, should be one with special dermatological knowledge. How many times is not even the most expert deceived, apart from microscopic examination, by tinea tonsurans lurking under the garb of an impetigo or seborrhoea! The eyesight of the children is considered at length, and the appointment of specialists in this department has been of the greatest assistance in bringing to light the wide prevalence of defective vision, and in calling attention to the great importance of free-arm drawing upon the blackboard, instead of cramming the accommodation by the use of small cardboard squares. The year has been one of progress, as indicating that the principles of hygiene are surely becoming more recognised by our educational authorities.

**Mumps and Pancreatitis.**

That mumps run an uninterrupted course to recovery is the common experience of medical practitioners. Sometimes, however, there is a considerable amount of pyrexia, accompanied by nausea and violent pains in the epigastric region, and as a rule these symptoms are ascribed to some hepatic trouble, although unaccompanied by icteric discolouring of the skin. From a study of quite a number of such cases, M. Simonin has, however, come to the conclusion that the symptoms are those of pancreatitis. Out of 652 cases of mumps, he found that the pancreas was infected ten times, that the attack was very sudden in its onset, and lasted but a short time, seldom exceeding seven days. On examining the gland he found it infiltrated with serum, soft, and oedematous, and that by its increased size it pressed on the colic axis and the semi-lunar ganglion of the sympathetic. That parotiditis can be associated with such a serious disease as pancreatitis should be sufficient to ensure that it receives due attention from the physician and to prevent its being relegated to the prescribing chemist or the domestic remedies of the nursery.

**The Physique of the Alien.**

Many medical men in London and our other large cities, especially those connected with hospitals, have abundant opportunity of forming an opinion respecting the physical aspect of the alien immigrant question. The report of the Royal Commission just issued contains much of the greatest importance to the welfare of the country. It will be remembered that it was the duty of the Commission to inquire into the character and extent
of the evils which are attributable to the unrestricted immigration of aliens, especially in the Metropolis, the measures which have been adopted for the restriction and control of alien immigration in foreign countries and in British Colonies; and to advise what remedial or precautionary measures it is desirable to adopt in this country, having regard to the above matters and to the absence of any statutory power to exclude or expel any individual alien or class of aliens from its borders. The Commission have held forty-nine public sittings and examined 175 witnesses. Their conclusions are of much practical importance, and, it may be hoped, will speedily bear fruit. Amongst much that is of particular interest to the medical mind, the evidence bearing on overcrowding brought about by the influx of aliens should be studied carefully. Overcrowding lies at the root of much of our distress, and the coming of the destitute foreigner does much to perpetuate the evil. Physicians at our Metropolitan hospitals have abundant opportunities of observing the ignorance and superstition of the aliens that flood the eastern parts of London, and indeed no considerable part of out-patient work is taken up with attending to the ailments of aliens who should never have been permitted to be dumped down on our hospitable shores.

Drainage in Abdominal Surgery.

The practice of employing drainage tubes in abdominal operations seems likely to follow that of the clamp into the limbo of discredited appliances, and a formidable blow to its prestige has been dealt by Professor Olshausen, the distinguished German gynaecologist. His personal opinion on the subject may be inferred from the fact that in 1,555 laparotomies, during the last six years, he only had recourse to drainage nine times; indeed, he recognises only one indication for its use, viz., the existence of an intra-abdominal abscess cavity which continues to suppurate. Obviously, no conscientious surgeon would consent to employ drainage in all his cases merely for the purpose of obtaining statistics to prove its undesirability, so Dr. Olshausen bases his argument on a study of 113 cases in which most surgeons would have drained in view of the circumstances. For instance, in 65 cases in which there was accidental contamination of the peritoneum with pus or other infective material, in spite of non-drainage he only had fourteen deaths. Moreover, he only had four deaths in 33 cases of typical pyosalphinx, and he was even more fortunate in cases in which there remained extensive raw surfaces, ten cases having no mortality. Even when there has been accidental perforation of the bladder or intestine he obtained good results in the absence of drainage. In lieu of drainage he advocates careful cleansing and drying of the surfaces and closure.

Arsenicated Beer.

The report of the work of the Government Laboratory just issued, for the year ending March 31st, clearly shows that arsenicated beer is not altogether a danger which has passed. Eleven hundred and seventy-three samples of beer, malt, and brewing materials were tested for arsenic, and in forty-one instances a very notable amount was present. One sample of wort contained 1-366th of a grain of arsenious oxide per gallon, and hence a substitute for hops. "Hop Compo," had been used and was found to contain ½ a grain of arsenious oxide per pound and 35 grains of oxide of antimony per pound. The "Hop Compo" had been prepared by a druggist who deals in veterinary medicines, and some of the vessels used in making horse-powders had also been used in preparing "Hop Compo." Manifestly, the beer-drinkers are not even yet out of the wood, and the teetotallers may still have good grounds for rejoicing.

Dr. J. T. Horron Davies has been placed on the Commission of the Peace for the borough of Leicester.

Dr. Robert Jones, resident physician and superintendent of the London County Asylum, Claybury, has been enrolled an Honorary Associate of the Order of St. John of Jerusalem.

Colonel F. Howard, Army Medical Service (retired), has been appointed President of the Board of Medical Officers before which the physical examination of candidates for Army commissions in London will be held this week.

Correspondence.

TUBE PERILS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The appalling calamity which has occurred in Paris and caused a shudder of horror to run throughout the civilized world will bring to the popular notice the sure ground for the anxiety which for long has been apparent in many thoughtful minds. Man, in his desire for centralisation, has congregated in such immense numbers that not only the provision for habitation, but the problem of locomotion is driving him to adopt new means and methods fraught with danger and fruitful in disaster. In order to secure speedy transit it is necessary to burrow into the bowels of the earth or trust to the uncertain wind-driven vagaries of the balloon. The rapid extension of underground travel is introducing elements which threaten the welfare of the people and open doors to dangers hitherto only dealt with in fiction.

With the honeycombing of our Metropolis with tubes and fast-lifting trains propelled by a force powerful in restraint but deadly in disorder, it is incumbent that no effort should be spared to limit the possibility of accident or prevent the occurrence of any disaster.

The danger prominent in the minds of all is that arising from fire, and in spite of the naturally reassuring expression of opinion given by those financially and otherwise interested in underground locomotion, we are of opinion that much more might be done to safeguard the public than is at present even attempted.

The disaster which happened at Liverpool is still fresh in one's memory, and should a fire once gain a foothold in a deep, single tube, where the carriage fits like a pistol bullet and means of exit are practically non-existent, and where the permanent way is laid with fully-charged electric rails, as in our "Tuppenny Tubes," the passengers would find themselves in a death trap from which escape would be impossible.

Familiarity is in danger of breeding contempt, and the public mind is readily lulled into a sense of security. It is incumbent, however, upon all responsible for the safety of the traveller to insist on the conduct of such measures as shall diminish the risks to a minimum.
It is most desirable that the motors and carriages should be constructed of non-inflammable material. The same should be the case with regard to sleepers, and the tunnel itself, and also the stations.

It is most necessary, also, that means should be provided whereby immediately the occasion may arise connection with the current may be cut off. It should be possible to detach the motor at a moment's notice, and the driver should be in direct communication with every car man.

It is interesting to note that the chief inspecting officer of railways for the Board of Trade, Colonel Yorke, in his evidence before the Joint Select Committee on the question of underground railways for London, clearly foresaw the possibility of the occurrence of such an event.

Every day experience affords proof enough of the inadequacy of the Metropolitan tubes. Even at the best of times ingress and egress is slow and difficult, and the lifts are conspicuous for their foolish arrangement whereby filling and emptying is accomplished from the same side. Both on the trains and at the stations a handy supply of water, and convenient fire extinguishers are conspicuous by their absence. In the smoking cars lighted matches are often recklessly thrown about, and much of the material used in the construction of the cars and certainly much of the armor of the passengers is anything but non-inflammable. Let us hope that out of the terrible catastrophe that has cast a gloom over Paris, some good may accrue.

I am, Sir, yours truly,

Y. N. K.

Literature.

YEAR-BOOK OF MEDICINE AND SURGERY. (e)

This excellent year-book now occupies the foremost place among works of this class, originating in America, and due entirely to trans-Atlantic energy and skill, it is not unappreciated on this side of the "berring-pond," and we hope it may not be long before it assumes a right to the title of "international," not only in spirit, but actually in name, and to this end we suggest the advisability of obtaining collaborators in this country and at present the work is essentially American, although it is only fair to say that the editors do not appear as a general rule at least, unduly biased in favour of "home products." These volumes well maintain the high level of excellence attained in previous years. But few changes appear to have been made in the staff and general form of presentation. The departments of ophthalmology and laryngology have been wisely united under the editorship of Dr. D. Braden Kyle and Dr. George Fetterolf.

In the volume devoted to Medicine Drs. A. Stengel and D. L. Edsall deal with general medicine; Drs. Louis Starr and A. Hand, jun., take pediatrics; Drs. David Riesman and A. O. J. Kelly retain direction over pathology and bacteriology; Dr. Archibald Church controls the section on nervous and mental disease; Drs. Louis A. Duhring and M. B. Hartzell deal with diseases and syphilis; and Drs. W. Wilcox and A. A. Stevens epitomise materia medica, experimental therapeutic and pharmacology; Dr. G. N. Stewart contributes an all too short summary of physiology; Drs. John Marshall and J. H. W. Rhein present legal medicine; Dr. S. W. Abbott writes on public health and preventive medicine, and Drs. Walter Jones and Reid Hunt are responsible for the section on physiologic chemistry.

In the Surgery volume Drs. J. Chalmers Da Costa and J. H. Gibson present the new features of general surgery; Drs. B. C. Hirst and W. A. N. Dorland deal with obstetrics; while Drs. J. M. Bailey and W. A. Dorland take urology; Drs. V. P. Gibney and J. H. Waterman furnish the summary on orthopedic surgery; Drs. H. F. Hansell and W. Reber are responsible for ophthalmo-logy; Drs. D. B. Kyle and G. D. Macdonald on dermatology, and so forth; little but of their critical function. The initials of authorities quoted should always be given; to find, as we do, the name of Smith without further adornment is not particularly identifying; indeed, we should not object to see sometimes the habitat of the worker indicated within brackets. More illustrations might be given with advantage. The Index needs improving, and should be divided into subject and name indices. The volumes are too heavy for convenient handling.

NURSING. (c)

Sir Henry Burdett's admirable, and now four-year-old, guide to the nursing profession, fully maintains its high level of excellence. By a happy chance the present volume bears no date. The work is admirably conceived, and has been most satisfactorily carried out. Of course, where so many scattered and dilatory individuals have to be sought out for up-to-date reports it is unavoidable that certain errors and commission should be noticed. But as far as we can gather great efforts have been made to secure the most recent and trustworthy information, and certainly in extent of material, comprehensiveness of excellenACE of arrangement and general convenience and utility as a work of reference, Sir Henry Burdett is to be congratulated. The volume is one which every nurse should possess and a copy should certainly be within reach of every practitioner. There is a very practical summary of the various requirements of the different schools, an outline of the principal laws affecting nurses, and elaborate details concerning general and special hospitals and their administration which train probationers. Particulars are also given of various nursing institutions and private nursing agencies and homes; and information will be found concerning Government, county, and municipal hospitals and institutions in Great Britain, where nurses are employed, but not trained. The section on Colonial, American and foreign hospitals and nursing institutions we shall hope to see much extended in the next issue. In these days of popular perperegrination, when an Englishman seems happiest away from home, it would be well that nursing homes providing English-speaking nurses on the Continent were all duly recorded in such a volume as this. The work contains a short chapter on training schools for attendants on the insane, and it might be well to add particulars concerning the special training needed for the adequate care of inebriate cases. We think also that more attention might, with advantage, be devoted to the somewhat special training now needed for the rapidly increasing sanatoria. A closing section indicates the pros-visions which have been made regarding provident funds, examining bodies, and the like, with the benefit of nurses. The work is issued at so remarkably low a price that it is brought within ready reach of those for whom it has been more particularly prepared.

THE HUMAN MACHINE. (c)
Mr. Nisbet’s very suggestive and exceptionally interesting study of mankind, first issued in 1895, and the present copy before us is the third reprint, which would seem to indicate that the work has passed beyond the mere reviewer’s reach and received that approval from the thinking public which it undoubtedly deserves. The work is certainly deserving of wide consideration, and in style and substance is peculiarly suited to present-day attitude of thought. We certainly agree with all Mr. Nisbet’s views and suggestions; indeed, many sections, we believe, are so heterodox that they should be studied with critical discernment; but we consider the work is one which all interested in the evolution of the human race should not neglect. Certainly the work is one which is particularly attractive to the mental mind. Much of Mr. Nisbet’s presentation is, perhaps, too materialistic, or, at all events, too confined, and he loses not a little by the occasional assumption of an altogether unscientific dogmatism. A wide extent of ground is covered; medical readers will, perhaps, be most interested in those sections dealing with the automatic action of the brain, vision, the painlessness of death, sexual distinctions, and methods of race improvement, but almost every page presents features of interest.

We think Mr. Nisbet might greatly increase the value of his work for serious students if in the next edition he could provide references to the various authorities on which he bases his statements, and builds up some of his somewhat fantastic contentions. A particularly graceful example of Mr. Nisbet’s style of work portrayed, we would refer readers to the picturesque description of Lourdes and its pathetic pilgrims. The printing and general get-up of the volume is good and attractive.

MATERIA MEDICA AND THERAPEUTICS. (b)
This first volume of this excellent treatise on materia medica was favourably reviewed in The Medical Press and Circular, of September 25th, 1901. We regret to hear that shortly before the completion of the present volume the author died after a prolonged and painful illness. He had, however, practically completed his manuscript notes, and their arrangement has been undertaken as a labour of love by his friend, Lieutenant-Colonel C. F. Lukas, M.B., F.R.C.S., of the Indian Medical Service, and now Professor of Therapeutics in the Calcutta Medical College. These two small volumes contain a compressed and revised form not only of an abstract of our knowledge of therapeutics, but many original observations culled from the author’s experience. The work naturally deals fully with those articles of materia medica which are in common use in India, and it will be found a useful supplement to the but little known Indian and Colonial Addendum to the “British Pharmacopoeia” of 1900. It is specially adapted to the requirements of those who propose practising their profession in the East, and we feel that we can recommend it with every confidence.

ROSS ON MALARIA. (c)
This short memoir contains the report of Professor Ross’s twelve days’ survey of Ismailia and district regarding the prevalence of malaria and the best measures for its eradication. It would seem that the whole of the irrigation system of Ismailia is free from larvae of anopheles, and is not favourable for their propagation, while the waters which really occasion the malaria are the most shallow and insignificant surface pools which it is well to find could be filled up or drained away without detriment to cultivation or irrigation. Major Ross discusses the various measures recommended for the purposes of dealing with mosquitoes, but considers the best method to aim at their extirpation, and in the present report he indicates how this may still be accomplished with the minimum of labour and the maximum of success. The report is an interesting and valuable contribution to preventive medicine.

CONTEXEVILLE. (a)
This interesting brochure is written by one who is not only proud of his connection with the development of the attractive and much lauded Contrexeville, but convinced of its advantages as a health resort. Dr. Debout d’Estrees sees in the excess of uric acid in the blood “the fons et origo of many morbid conditions, such as gravel, gout, gouty diabeties and eczema, and his thirty-five years of practice at Contrexeville has afforded him abundant evidence of the benefit which may be received by undergoing the curative treatment provided there. The work is primarily addressed to non-medical readers, but in spite of a somewhat dominant egotism which pervades these pages the physician who is desirous of learning something as to the nature of the waters of this popular health resort may profitably consult it.

MANUAL OF OPHTHALMIC PRACTICE. (b)
This is just the sort of work on the eye required by students and practitioners. It is eminently a practical treatise, the more recondite aspects of the subject being ignored. The present edition has been greatly improved, and the page presents features of interest. The manual is re-written, and certain faults of omission in the first edition have been remedied. We note en passant that no mention is made of the valuable assistance to be derived from the use of fluorescein in the diagnosis of superficial corneal ulcers, although its use is recommended in that of injuries to the cornea. The value of this manual should, we venture to suggest, be greatly enhanced by the addition of a table of pharmaceutical formula, or by the incorporation of detailed prescriptions in the text. We are told, for instance, that in the treatment of certain ulcers of the cornea we may prescribe “the yellow oxide of mercury ointment combined with atropine”—but how much curare? The view of the present neglect of materia medica and pharmacy in medical education it is not desirable to assume any knowledge of the kind, and from every point of view it would be preferable to give specific directions.

The work is one which will meet the requirements of practitioners other than specialists. It is liberally illustrated, and the literary execution leaves nothing to be desired.

JACOBI’S "THERAPEUTICS OF INFANCY AND CHILDHOOD." (c)
Nearly seven years have elapsed since this treatise first saw the light. In the following year a second edition appeared differing in many respects from the first, inasmuch as new material was added and many of the chapters entirely rewritten. A third edition has now been published, and although, in its general character, the work is unaltered, many additions have been made to the text. In the space at our disposal it is impossible to do justice to a volume such as this. At the same time we shall endeavour to briefly in-
PUBLIC HEALTH. (a)

This standard guide to laboratory work in its bearings on public health investigations has now been brought up to date, and a new chapter on bacteriology is contributed by Dr. W. G. Savage, Medical Officer of Health for Colchester. Advantage has been taken of the opportunity afforded by the issue of this, the third edition to substitute more modern methods of research in certain departments.

The author takes a firm stand in condemning the indiscriminate use of preservatives such as borax, boric acid, and the like, on the ground that the positive results obtained by many far outweigh the negative results obtained by others.

The praise which we accorded to previous editions is applicable with even greater emphasis to the present August number. It may safely be recommended as a clearly written, comprehensive, and in every respect trustworthy guide to this very important department of public health work.

LITERARY NOTES.

In consequence of the necessary support not having been accorded to the Quarterly Medical Journal, it has ceased publication with the August number.

***

Dr. Charles Reinhardt contributes a very attractively illustrated paper on "Bagnères-de-Luchon," to our artistic contemporary, The Heathen Coney, which number also contains an interesting communication on "The Financial Aspect of the Open-Air Treatment."

A very convenient list of hospital addresses is published, which is likely to prove of much service to medical men having to deal with this peculiarly difficult class of case, and has been compiled by the authorities of the Friends' Temperance Union, and we understand that copies may be obtained from 15 Devonshire Street, London, E.C.

***

The Society for Spreading Information about St. Michael's, has published a brochure which seeks to indicate the advantages of St. Michael's, the largest and richest of the group of nine islands which make up the Azorean Archipelago, as a desirable health resort.

To the American Quarterly Journal of Inebriety, Dr. A. Forel, of Switzerland, contributes an interesting historical study of the International Anti-Alcoholic Congresses and the Temperance Movement on the European Continent.

***

Mr. A. G. Bradley, the author of "Highways and Byways in North Wales," and Dr. J. W. Geary Grant have published an attractive booklet on "Llangollen and its Neighbourhood," seeking manifestly to attract visitors to the waters and baths of this comparatively little-known but in many ways very charming health resort.

OBITUARY.

WILLIAM SMOUT PLAYFAIR, M.D.ED., F.R.C.P., LOND., LL.D.ST.AND.

The death is announced of Dr. William Smout Playfair, the well-known obstetric physician, at St. Andrews last week. Dr. Playfair had been in indigent health for some years, and went a few months ago to Florence, where he had an apoplectic seizure, and although he improved sufficiently to allow of his removal by easy stages to St. Andrews, he gradually sank. Dr. Playfair was a brother of the late Lord Playfair, but eighteen years his junior, being born in 1836. His father, Dr. George Playfair, was Inspector-General of Hospitals, Bengal, and did not return to this country.
until 1842. His professional training was obtained at the Edinburgh University, where he graduated as M.D. in 1836, at the age of 20! Dr. Playfair, following his father's footsteps, entered the Bengal Medical Service and served in Oude through the Mutiny. His stay in India, however, was not long, for seven years later, after discharging the duties of assistant surgeon and acting professor of surgery in the Medical College of Oude, he returned to England on account of his health. At the age of 27 he began practice in London as an obstetric physician, and joined the staff of King's College Hospital, where for twenty-five years he was professor of obstetric medicine, retiring in 1868. He had maintained his connection with the institution in virtue of his position as consulting physician to the hospital. He was also consulting physician to the General Lying-in Hospital and the Evelina Hospital for Children, and was at one time president of the Obstetrical Society of London, and examiner in midwifery to the Universities of Cambridge and London.

Dr. Playfair was Physician-Accoucheur to the Duchess of Saxe-Coburg-Gotha and the Duchess of Connaught, and the gratitude of the Crown Princess of Roumania for professional services in the same capacity was commemorated by the insignia of a Grand Officer of the Crown of Roumania, presented to him by the King of that country.

In recognition of his eminence as a gynecologist, St. Andrews University made him an hon. L.L.D., in 1885, and the fact that his reputation was not confined to this country was shown when the American and Boston Gynecological Societies conferred on him honorary fellowships. In this connection also it may be mentioned that his "Treatise on the Science and Practice of Midwifery" has not only passed through nine editions here, but has been translated into many foreign languages.

One incident in his career attracted widespread attention, and is doubtless still fresh in the minds of his contemporaries. An action was brought against him in 1866 by a lady patient for a breach of professional confidence, which resulted in £12,000 damages being awarded against him. Although the verdict met with general approval in professional circles, it was felt that Dr. Playfair had been guilty of nothing more than an error of judgment, and a sympathetic testimonial was presented to him by a number of the most eminent men in the country.

Dr. Playfair in 1864 married Emily, daughter of Mr. James Kitson, of Leeds, by whom he had one son and three daughters. The funeral took place at St. Andrews, where his brothers, Lord Playfair and Sir Lambert Playfair, are both buried.

DR. GEORGE BALFOUR, OF EDINBURGH.

We regret to announce the death of Dr. George Balfour, one of the oldest and most highly respected of Edinburgh physicians, which took place at his residence in Colinton on August 9th. Dr. Balfour had been in failing health for some months past. He retired from practice about five years ago, and passed the evening of his days in Colinton, a quiet village a few miles from Edinburgh, of which his father, the Rev. Lewis Balfour, was parish minister. Dr. Balfour was well-known throughout all English-speaking countries by his books on heart disease, the second of which, "The Senile Heart," was the outcome of long years of ripe scientific research, and was published just about the time the author retired from active work. The scientific value of his writing was enhanced by a charming literary style, which carried the reader on and made a study of his books a pleasure. He died, as he lived, all too rare in these days of "Teutonic handbichter.

He was for many years a physician to the Royal Infirmary, and a successful clinical lecturer and teacher. He was one whose enjoyed the unusual somewhat alarming to nervous students. On his retirement from the active staff he was made a consulting physician to the institution, and held a similar position in the Royal Hospital for Sick Children, the Leith Hospital, and other medical charities. Up to within a few years of his death he was on the acting staff of Chalmers' Hospital. He was made a Physician-in-Ordinary to the late Queen Victoria, and continued to hold a similar office in the present reign. Dr. George Balfour took a deep interest in the medical education of women, and co-operated actively with Dr. Jex-Blake in the conduct of the classes for women in her school, and, after the absorption of that school into the present one, continued to show his interest in the subject by acting on the Board of Management of the Bruntsfield Hospital. Apart from his professional eminence, Dr. Balfour was widely known by his relationship to the late eminent author, Mr. R. L. Stevenson, mother of the youngest daughter of the Rev. Lewis Balfour, and he was therefore one of Dr. Balfour's nephews. Dr. Balfour was twice married, and is survived by a widow and family, three of whom are medical men. His youngest son is a practitioner in South Africa, and was one of those besieged in Ladysmith.

DR. STONE, OF OMAGH.

We regret to announce the death of Dr. Stone, of Omagh. The deceased gentleman qualified in 1871, and not long afterwards was elected medical officer to the No. 1 dispensary district of Omagh Union. For many years he enjoyed a large and lucrative practice in Omagh, and its neighbourhood, where he was both respected and loved. He married rather late in life, and leaves a widow to mourn his loss.

DR. R. B. THRELFALL, OF CARRICK.

We regret to announce the death of Dr. R. B. Threlfall, of Carrick-on-Shannon, who died from an accidental wound of one of the large arteries of his thigh, occasioned by his falling on a water-bottle. He was an M.B., B.Ch., B.A.O., R.U.I., in 1868, and soon afterwards was elected medical officer of the Aughrim dispensary district, Carrick-on-Shannon Union.

DR. WILLIAM E. CROZIER.

The death is announced of Dr. William E. Crozier, of Wyalong, New South Wales. Dr. Crozier obtained the L.R.C.S. and P.I. in 1883, and soon afterwards became resident medical officer to the Meath Hospital, Dublin. He went to Australia for health reasons, and settled in Brisbane, Queensland, and was on his return journey when he was seized with a fatal attack of haemorrhage on June 14th.

Medical News.

Indian Medical Service.

The British Medical Association have issued an appeal to members of Parliament to urge upon the Government the necessity of seriously considering the position of officers in the Indian Medical Service. The principal claims advanced on behalf of these officers are (1) that they should be allowed to complete thirty years' service before compulsory retirement at the age of 55, and that every year's service thereafter should qualify for an additional pension of £40 a year; (2) that the pay of the Indian Medical Service should be increased proportionately with that of the Royal Army Medical Corps; (3) that the officers who entered the Indian Medical Service in what are known as the "intermediate" years should now be allowed to count the four months spent at Netley as service for pension; (4) that the post of chief medical officer of the forces in Dublin should be included under medical officer's service; (5) that all newly-appointed medical officers should remain for at least six months at district headquarters, where they can procure a teacher to enable them to pass the required language examination, and should be granted the officiating pay of any charge they may hold during their first year of service or until they have had a reasonable opportunity of passing their examination, as in the case of officers of the Indian army; (6) that the privilege of free railway
transit for their horses should be restored to medical officers; (7) that the reduction of the grade pay in the civil branch and all higher class civil officers be abolished; and (8) that the Director-General of the Indian Medical Service should have the rank of lieutenant-general (as the Director-General of the Army Medical Department now has), with a separate pay and a seat on the Viceroy's Council, whilst the administrative medical officers of the different provinces should have seats on the provincial councils and real control of the appointment and all officers serving under them.

A Hospital without a Medical Staff.

It appears that the Folkstone Sanitary Authority does not provide medical attendance for patients confined to the local isolation hospital, and the medical officer of health naturally declines to attend unless paid his fees. This fact was elicited the other day in a county court action for the recovery of fees for attendance on such a patient, and the judge very rightly commented in somewhat drastic terms on this state of things. The matter is one in which the Local Government Board might be expected to lend a helping hand, for it is unquestionably a disgrace to this fashionable watering place.

Compulsory Vaccination and the Medical Profession.

The Worcestershire County Council has passed the following resolutions:—(1) That primary vaccination be made compulsory (as under the present Act); (2) that vaccination at about the age of twelve should be made compulsory in the same way; (3) that no certificate of vaccination be recognised which does not comply with the requirements of the Local Government Board as to the number, area, and size of the vaccination cinctures; (4) that sufficient facilities should be provided for obtaining a ready supply of glycerinated calf lymph; (5) that the carrying out of the vaccination laws should be transferred to County Councils.

Lord Ivecagh's Gift to Dublins Hospitals.

The following trustees, it is stated, have been appointed for the distribution amongst the Dublin hospitals of the gift of £50,000 from Lord Ivecagh, as a souvenir of the King's visit—Lord O'Brien of Killenford (chairman), Mr. Charles E. Marten, D.L., the Right Hon. Jonathan Hogg, Mr. Joseph Toddiner Pim, and Lieutenant-Colonel Adderley (who is a director of Guinness's Brewery).

Measles has halted the Study of Disease in Children.

The following officers and members of the Council were elected at the annual general meeting held on July 23rd, for the session of 1903-1904:—

Councillor.—F. Ford Anderson, M.D.; Charles W. Ciulla, M.D.; J. S. H. G. Curtis, B.S.; Herbert L. Carre-Smith, Clinton T. Dent, M.C.; Charles N. Gwynne, M.Ch. (Sheffield); Edmund Hobhouse, M.B. (Brighton); Henry R. Hutton, M.B. (Manchester); Robert Hutchinson, M.D.; Francis Jaffrey, Charles John MacAlister, M.D. (Liverpool); Alexander Morison, M.D.; Robert H. Parry (Glasgow); J. Porter Parkinson, M.D.; George Pernet, Henry Betham Robinson, M.B.; Sidney B. Smith, M.B. (Belfast); Harold J. Stiles, C.M. (Edinburgh); Frederick Taylor, M.D.; J. W. Thomson Walker, C.M.; Richard H. A. Whitelocke, C.M. (Oxford); Alfred W. Wills, M.D.

Hon. Treasurer.—R. Clement Lucas, B.S.; Hon. Secretary.—George Carpenter, M.D.; Theodore Fisher, M.D. (Bristol); George A. Sutherland, M.D.

Non Res in Iudem.

Mrs. Beesie Bosquet is decidedly unfortunate in having her name make a bad impression on the local public. In 1899 she was charged with causing an action for damages against the Greville Bath, in Upper Berkeley Street, by reason of a burn she alleged to have sustained there, and at the Leominster assizes last week a second action of the same kind was tried in which she claimed damages from the Harrogate Corporation for a similar accident inflicted by the same system of thermal bath. We are, therefore, unwise to go to the same ground as in the last case, and we are confident that the lesion complained of was of the nature of a burn, but the jury arrived at the opinion that such was the case, and awarded damages to the amount of £250, which was set aside.

Small-pox at Cambridge.

The epidemic of small-pox at Cambridge has been circumvented and is dying out. Only one or two fresh cases have been notified during the last three or four days, and the number of cases actually under treatment has fallen to sixty.

A Trypanosoma Expedition.

The Liverpool School of Tropical Medicine, with characteristic initiative, have decided to dispatch an expedition to the Congo Free State next month, with the co-operation of the Congo Government, to study the sanitary conditions of Boma, Leopoldville, and some other important centres and to make recommendations for improvements where such appear to be necessary. The delegates will resume the study of trypanosomiasis in human beings and animals begun by Dr. Dutton in 1901, including the relationship of trypanosoma to sleeping sickness. The Congo Free State has promised generous contributions towards the expenses, which are likely to be heavy. The "study" will entail drives of big game up the country, with the object of investigating the blood of wild animals. The expedition will start for the Congo by the steamer "Albertville."

Malaria and Mosquitoes.

MAJOR RONALD ROSS, in a letter to The Times, calls attention to the progress that has already been accomplished in certain regions in Egypt in the destruction of the ubiquitous mosquito. Several of the marshes in the neighbourhood of Ismailia have been filled in or drained, and operations are in hand with regard to others. Even now, a movement to clear the country free from the insect pests, and the men engaged in the work are no longer troubled by them. The number of cases of malarial fever has fallen to but a fraction of what it was at corresponding periods last year, and if the eliminated the recurrent cases the disease might almost be regarded as non-existent. This is a very brilliant result of the scientific application of recently discovered facts, and is full of promise for the future. It is hardly necessary to point out that these methods are not applicable to all malarial districts, but special measures will have to be devised to meet particular conditions. It is sufficient for the time being that the validity of the principle has been established.

The Medical Graduates' College and Polytechnic.

The unsatisfactory state of the college finances has rendered it necessary to take prompt and urgent measures to restore equilibrium. The first step decided upon has been to suspend the issue of the Journal during the months of August and September. A sum of £1,900 is required to meet immediate liabilities, and contributions are earnestly invited from members and others. The amount will be required by the end of September, so that there is no time to be lost. The Council are sanguine that, if the present crisis is tide over, the adoption of the scheme which they have elaborated will ensure a balance on the right side. We could wish that an institution of such promise and of such ascertained utility were not possessed of sufficient reserve funds to ensure its viability, but the indispensable millionaire has not yet come forward, and its continued vitality is therefore uncertain. It would be a very great pity were this institution to be allowed to die for lack of adequate support, but unless substantial contributions be forthcoming, and that promptly, its future will be jeopardised.

The Medical Profession.

The preliminary entrance examination for the Conjoint Diplomas of the Royal Colleges of Physicians and Surgeons in Ireland will be held on Monday, September 21st. The winter session will commence in October. Prospectus, entrance forms and guide for medical students can be obtained, post free, on written application to the Registrar, Royal College of Surgeons, Stephens Green, W., Dublin.
NOTICES TO CORRESPONDENTS.

AUG. 19, 1902.

NOTICES TO CORRESPONDENTS, Short Letters, &c.

Correspondents requiring a reply in this column are particularly requested to make use of a distinctive signature or initial, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

M. C. CORBETT (Messina).—Your paper on "The Fixation of Billiary pigments in the placenta during Pregnancy" is marked for early insertion.

M. C. CORBETT (Messina).

MEDICAL AFFAIRS IN SOUTH AFRICA.

We scarcely know whether to describe matters medical as in the "progressive" state in our South African Colonies, most things are thus labelled nowadays; in any case, they would hardly be considered behind the times if we may call a few items from a couple of columns in the "South Africa Medical Record," as fair examples. Thus, we have a qualified lady doctor advertising as a "Specialist in Venereal," immediately under this is the full, undivided lineage as if served through the war, for steaming nine horses, and being sent to prison for two years; following which Dr. H. J. E. B. M. C. B. was insisted for the cause of the death of a patient by means of an illegal operation. In another column the Editor writes: "We have had brought to our notice during the month three complaints against medical practitioners on ethical points." The medical problem would thus appear to be as serious as that of labour!

MAJOR R.—We cannot undertake to 'read' your MS. for the purpose of forming an opinion on its validity for publication. You might, however, have it type-written for submission to a publisher. The title strikes one as ill-chosen.

ANTIVITAM MINUTIA.

It must be admitted that many anti-vitamist do not base their justification on a faith without works. Among the members of the large group they hold a foremost place for vivacity and vitality, though not deserving exceptional distinction for versatility. Their versatility is also made for admiration, while their vituperation and ofttimes virulence in verbal warfare is indicative of a virility which needs exceptional virtue to withstand in a spirit of victory the attacks of the world's famous "Lancet Towers." In the Albert Bridge Road has been transformed into "The Antivitam Minutia. We deal with interest the records of the doings of this latest "House of Howe."

DA V. J.—It is not at present possible to forecast what will be the outcome of these prolonged negotiations, and it would be impolite to discuss conclusions as yet unformulated.

Dr. N. M.—We do not agree with your views on the absence of any necessity for our on better evidence of death after said taken place. It is not enough to certify 'as I am informed,' for this leaves the door open to numerous abuses. The subject has been very carefully considered in our columns and elsewhere, and no good purpose would be served by airing opinions which are at variance with the general trend of professional views on the question.

Our facetious correspondent A. D. sends us the following:—

DIAGNOSIS AT FAULT.

The patient cannot live another day.

We hear an old physician rashly say.

We now disprove the truth of what he said.

That patient has lived another day.

The inventor of the Murphy button hails from Chicago.

We imagine a more suitable birth-place would have been Connecticut?

Appointments.

KIRSCHNHEIM, M.R.C.S., L.R.C.P., Lond., Certifying Surgeon under the Factory Act for the Newport District of the County of Salop.

LAVERTY, J. P., L.R.C.P. & S. Edin., Certifying Surgeon under the Factory Act for the Dundalk District of the County of Louth.

SKELTON, G. M. C. A., Medical Officer to the Nottingham Board of Guardians.

Vacancies.

Devon County Asylum, Exminster.—Third Assistant Medical Officer, Salary £250 per annum, with board, lodging, washing, and attendance. Applications to the offices of the Council, 1, Pillar House, Exeter.

Willesden Urban District Council.—Medical Superintendent, Salary £300 per annum. Applications to the Hon. Secretary, Willesden Town Hall, W.4.

Noble's Isle of Man General Hospital and Dispensary.—Resident House Surgeon, Salary £150 per annum. Applications to Dr. H. Tilly, Hon. Sec., 55, Groveon Road, Birkenhead.

Peckham House Asylum, Peckham, S.E.—Junior Assistant Medical Officer, Salary £150 per annum, with board, residence, and laundry. Applications to the Resident Licensed.

Hull City and County Lunatic Asylum.—Assistant Medical Officer, Salary £150 per annum, with board, apartments, washing and attendance. Applications to the Assistant Asylum Committee, care of the Town Clerk, Hull Town Hall.

The Cancer Hospital, Fulham Road, B.W.—House Surgeon. Salary £70 per annum, with board and lodging. Applications to the Secretary (See advert.)

Kent and Canterbury Hospital.—House Physician. Salary £90 a year, with board and lodging. Applications to the Secretary.

St. Peter's Hospital for Men, Sic., Henrietta Street, Covent Garden, W.C.—House Surgeon. Salary £100 a year, with board, washing and lodging. Applications to Irwin H. Beattie, Secretary.

Parish of St. Leonard, Shoreham.—Medical Officer. Salary £100 per annum. Applications to Robert Clay, Clerk to the Guardians, Clerk's Office, 51, St. Leonard's Road, Shoreham.

County Asylum, Whittingham, Preston, Lancashire.—Assistant Medical Officer. Salary £175 per annum, with furnished apartments, board, washing, and attendance. Applications to the Medical Superintendent.

Ballyshannon Union.—Medical Officer. Salary £100 per annum; also to act as Medical Officer of Health at a salary of £20 per annum. Immediate application to be made to J. B. Chish, Clerk of Union, (See advert.)

Deaths.

CATHERON.—On August 7th, at Thomas's House, Worcester, the wife of J. P. Cavenagh, L.R.C.P., of a daughter.

COTTRE.—On August 7th, at 50, Wallwood Road, Leytonstone, the wife of F. J. Cott, M.D., of a daughter.

GAMORI.—On August 12th, at 60, Rotten Park Road, Edgbaston, the wife of L., of a daughter.

HARVEY.—On August 2nd, at 117a, Queen's Gate, B.W., the wife of Sidney Harvey of a son.

HOLLOWAY.—On August 8th, at the Manor House, Houghton-le-Spring, Durham, the wife of James Gilpin Houseman, M.D., of twin daughters.

MARRIAGES.

OWEN—THREMBL.—On August 13th, at St. Mary's Church, Cowchington, Liverpool. George Chetwood Owen, M.B., son of John Owen Owen, barrister-at-law, Ryderham, to Ellen, third daughter of the late Charles Frederick Timbrill, of Stockport.

WILSON—EVANS.—On August 13th, at Christ Church, St. Michael's, Llandudno, to Michael Rervyn Wilson, M.D., of Derby, to Nora Kathleen Evans.

BIRTHS.

OPERATIONS—METROPOLITAN HOSPITALS.

WEDNESDAY.—St. Bartholomew's (1.30 p.m.), University College (2 p.m.), Royal Free (2 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. Thomas's (3.30 p.m.), St. George's (3 p.m.), King's College (3 p.m.), St. George's (Ophthalmic, 1 p.m.), St. Mary's (3 p.m.), National Orthopedic (10 a.m.), St. Peter's (2 p.m.), Samaritan (2.30 a.m. and 3.30 p.m.), St. Mary's (3 p.m.), Northern Central (2.30 p.m.), Westminster (2 p.m.), Metropolitan (2 p.m.), London Hospital (3 p.m.), London Orthopedic (3 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

THURSDAY.—St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), University College (2 p.m.), Charing Cross (3 p.m.), St. George's (London, 2 p.m.), King's College (2 p.m.), Middlesex (1.30 p.m.), St. Mary's (3 p.m.), Soho Square (2 p.m.), North-West London (2 p.m.), Chelsea (2 p.m.), Great Northern Central (Gynecological, 2.30 p.m.), Metropolitan (2.30 p.m.), London Orthopedic (3 p.m.), St. Mark's (3 p.m.), Samaritan (9.30 a.m. and 1.30 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

FRIDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), King's College (2 p.m.), St. Mary's (Palmers Green), Ophthalmic (10 a.m.), Cancer (2 p.m.), Chelsea (3 p.m.), Great Northern Central (2.30 p.m.), West London (2 p.m.), London Orthopedic (3 p.m.), Samaritan (9.30 a.m. and 1.30 p.m.), Throat, St. George's (3.30 p.m.), Soho Square (3 p.m.).

SATURDAY.—Royal Free (9 a.m.), Middlesex (1.30 p.m.), St. Thomas's (3 p.m.), University College (9.15 a.m.), Charing Cross (2 p.m.), St. George's (1 p.m.), St. Mary's (3 p.m.), Middlesex (3 p.m.), Soho Square (3 p.m.), St. George's (2 p.m.), Westminster (3 p.m.), Chelsea (2 p.m.), Samaran (Gynecological, by Physicians, 2 p.m.), Soho Square (3 p.m.), Great Northern Central (2.30 p.m.), West London (2.30 p.m.), l.Royal Throat (3.30 p.m.), Westminster (2.30 p.m.), Soho Square (3 p.m.).

Paris Clinical Lectures.

THE DIAGNOSIS OF A TUBERCULOUS ORIGIN IN ACUTE PLEURISY.

By Professor Dieulafoy.

Physician to the Paris Hospitals.

We are often required in practice to decide a question of the highest importance. A patient previously in excellent health has suddenly been attacked by acute sero-fibrinous pleurisy. The pleurisy presents all the characteristics of a typical pleurisy and presents the features of the so-called primary or frank pleurisy; the conditions under which this variety of pleurisy occurs seem to point to an a-frigore cause, yet, warned by experience, we distrust the mildness of the affection, and we ask ourselves, not without a certain anxiety, whether this apparently accidental pleurisy is not, in reality, a tuberculous pleurisy, a view which would, of course, greatly modify the prognosis.

How are we to solve a problem which is at times so difficult? In the case of an ordinary acute pleurisy are we in a position to state whether or not it is tuberculous? Such is the question which I propose to discuss in connection with seven patients who have been under treatment here during the present year. In order that we may not wander from the subject, I will first of all define its scope.

When I commenced my medical studies cases of acute pleurisy were all classed under two headings—primary and secondary. Primary pleurisy was thought to be due to a "chill," whence the name of pleurisy a frigore. Moreover it was called "idiopathic," meaning thereby that it was not secondary to any other pathological process. It was also entitled "frank" pleurisy, which put aside the idea of any constitutional taint. It is this primary, idiopathic, a frigore pleurisy which served as a type for the general description of acute sero-fibrinous pleurisy; in other words, it was pleurisy without any other qualification.

In contradistinction to this primary pleurisy, it was customary to describe the varieties of secondary pleurisy which follow on other affections—pneumonia, rheumatism, Bright's disease, &c.—or as consequent to neighbouring lesions, lesions of the abdominal and thoracic organs, &c. In this heterogeneous group of secondary pleurises, tuberculous pleurisy held a prominent position, but we had not yet become familiar with this primary pleuro-tuberculosis, and tuberculous pleurisy, especially, was regarded as a complication of pulmonary tuberculosis. Little by little the question of tuberculous pleurises has been elucidated, and it has been demonstrated that all cases of pleurisy are not necessarily alike. In the first category are cases of pleurises occurring in individuals suffering from obvious pulmonary tuberculosis, in a more or less advanced stage, with manifest pulmonary lesions, and bacilli in the expectorations. A pleurisy which occurs under these conditions is almost certain to be tuberculous, and, moreover, this is of but secondary importance in the matter under discussion; hence, in such a patient, the result of our investigations is known beforehand: this pleuritic patient is tuberculous.

In a second group we may place cases of pleurises which are supposed to be tuberculous. It may be that the lung is apparently intact; yet, in spite of this, we have our suspicions. Some are of tuberculous heredity (and personally I am strongly in favour of an hereditary influence in opposition to what was recently advocated at the London Congress), others have previously suffered from obstruse bronchitis from which they have recovered, haemoptysis which did not recur, fistula in ano which has been successfully operated upon, a so-called rheumatism which was in reality a tuberculous pseudo-rheumatism, the nature of which had been overlooked; others have had in childhood suppuration of the cervical glands of which the traces may be seen, a coxalgia which has left a slight limp, post-pharyngeal adenoids with latent tuberculosis of the tonsils. In short, the cases of pleurises belonging to this group have been preceded at a more or less distant date by localised tuberculous lesions of which the pleurisy is merely a sequel. They do not always present the appearance of a frankly acute pleurisy, for they often develop after a prodromal phase of undetermined duration, characterised by progressive loss of flesh and general debility. Clinically, I repeat, they are suggestive of tuberculosis.

Quite otherwise are the cases of tuberculous pleurisy, which we will now deal with. In these nothing suggests tuberculosis, neither in the past nor the present. The attack supervened when the patient was apparently in perfect health, without appreciable cause, though perhaps ascribed to a "chill"; just as is the case with tonsilitis or coryza. The onset and course of the pleurisy, the evolution of the effusion, the results of the thoracentesis (if resorted to) even the period of convalescence, all are suggestive of acute uncomplicated inflammation. This is the aspect of the patient suffering from pleurisy called primary or a frigore. But appearances are often deceptive, for this very patient having recovered from his attack of pleurisy will be found, a few years later, to be the victim of pulmonary tuberculosis in a more or less advanced stage, the pleurisy from which he recovered having been the initial manifestation of tuberculous infection which ran its course. (Jacquod phthisiogenus pleurisy.) Such another subject who has completely recovered from his pleurisy some time later succumbed to a tuberculous meningitis. Do not imagine that this is simple coincidence, for these cases are by no means rare; on the contrary, they are of frequent occurrence. These are the cases which drew attention and led to doubt being cast on the existence of the so-called a frigore pleurisy.

Dr. Landouzy was the first, in 1884, to clearly formulate the indictment, by divesting primary pleurisy, a frigore, of its ancient prerogatives. He affirmed that all cases of pleurisy not clearly proved to be otherwise are tuberculous even though the patient be to all appearances robust and healthy. MM. Keloch and
Vaillard supported this view, and it met with such a favourable reception that pleurisy *a frigore* soon lost much of its prestige.

Dr. Landouzy’s opinion did not, however, fail to meet with lively opposition; it was thought to be an exaggeration and cases were published to prove the contrary. Numerous observations were published, and a record of patients who had had attacks of frank acute pleurisy, *a frigore*, which, it was asserted, had no connection with tuberculosis, since these pleurisy had conspired to avoid it, leaving no traces, and were not followed either soon or late by tuberculous manifestations.

Let us discuss the question closely, for it is not without an interest to the future of a pleuritic patient to know whether his pleurisy is, or is not, tuberculous. First of all let us ponder over the pathological anatomy, what has been the cause of death in individuals who have suffered from pleurisy, so-called frank, *a frigore*, and note whether or not tuberculous lesions have been discovered post-mortem.

In a case published by Dujardin-Beaumetz, we have a patient who died suddenly from pleuritic effusion. This man did not present the slightest symptom of tuberculosis; his pleurisy appeared to be primary, and yet the post-mortem revealed tuberculous lesions of the lung.

An observation recorded by Dr. Landouzy may be taken as the type of pleurisy *a frigore*. A robust man, a baker, having no morbid antecedents, one night left the underground bakehouse where he was engaged in kneading, and several hours later was discovered to be in a public-house for a drink. On his way thither he "took cold," but went on with his work as usual, but the next morning he took to his bed. Then it was that the pleuritic symptoms supervened—a pain in the side, inspiratory trouble and fever. The pleurisy ran its course, and a few weeks later came under the care of Dr. Landouzy, in whose ward he died suddenly. At the post-mortem an abundant sero-fibrinous effusion was discovered in the right pleural cavity, and several tall deposits of tubercle, which had until then run a latent course, were discovered in the right lung. Although it had all the appearance of pleurisy *a frigore*, this pleurisy was nevertheless of a tuberculous nature.

In their work on the lesions and the nature of pleurisy, MM. Kelsch and Vaillard published a number of similar cases. A robust and well-built soldier was attacked by acute pleurisy. He died suddenly while talking to his wife, and when he was about to be removed to the Val-de-Grâce Hospital. At the post-mortem a copious effusion was found in the right pleural cavity and the pleura was covered with tuberculous granulations.

Another soldier of robust constitution was attacked by right pleurisy. The patient was reading beside his bed when he suddenly fell down and died. At the post-mortem a considerable effusion of the right pleura was discovered, and the pleura was studded with tuberculous nodules. These grave pleurises, according to MM. Kelsch and Vaillard, occurring in strong men, without the slightest tuberculous taint and running their course with every appearance of an ordinary pleurisy, would have been classed as ordinary inflammatory pleurisy had not death suddenly intervened and revealed their true nature.

I can recall two cases of interest in this connection. One was that of a man usually in good health who was attacked by right pleurisy, which he attributed to a chill. For several days the effusion went on increasing in amount, until it measured about two litres. Although the patient did not suffer from any dyspnoea, we decided to practise thoracocentesis. The patient objected and so the operation was postponed till night. An hour later this man tried to get out of bed, when he was attacked by a violent chill, followed by a considerable effusion. At the post-mortem, being desirous of knowing the exact quantity of the effusion, I practised thoracocentesis on the dead body and withdrew 2,200 grammes of yellow pleurisy fluid. In this man, in progress, for in the apex of the lung there was a tuberculous lesion.

The second case was that of a robust man with no tuberculous antecedents. His was an iceman, and was thus exposed to local chills. One day this man was attacked by pleurisy, and we found on the right side an effusion calculated to amount to about three litres. In the course of the next few days we withdrew three litres of the pleural fluid (one litre of this was blood). At the operation the patient felt much better, but the liquid continued to accumulate. A few days later this man had just had breakfast in bed when he got up, but had hardly taken a few steps when he fell, became cyanosed, and died. Wishing also to satisfy myself on this occasion as to the quantity of the effusion and the cause of the sudden death, I practised thoracocentesis on the corpse and withdrew 2,130 grammes of liquid. I then proved that the pleurisy which had thus been caused, was in reality tuberculous, since there existed tuberculosis of the pleura and a tuberculous focus in the lung.

An observation of M. Widal’s, to which I shall refer later, bears on the case of a lad who was attacked by pleurisy, apparently of the nature of an ordinary acute pleurisy accompanied by considerable effusion. The little patient suddenly died, and at the post-mortem there was found tuberculosis of the pleura in course of evolution.

You must admit that here we have a certain number of very suggestive facts. A number of robust people are attacked, whilst in perfect health, by frank pleurisy, called *a frigore*; they die suddenly and the post-mortem reveals the tuberculous nature of their pleurisy.

Sometimes, the individual attacked by frankly acute pleurisy recovers from his illness, and is supposed to be definitely cured; but, often, a few weeks or months later he is carried off by miliary tuberculosis or by meningitis, thus testifying to the tuberculous nature of his pleurisy. In 1884 a strong young man, aged 28, an engineer, entered my ward suffering from pleurisy *frigore*. Contracted three weeks previously, it led one to suspect tuberculosis; it was a typical case of frank pleurisy. I noted on the left side a considerable effusion, which I calculated to be about two litres; I commenced by withdrawing one litre of sero-fibrinous fluid, and then I stopped, for I made it a rule, in order to avoid any accident, never to withdraw more than one litre at a sitting. A few days later I withdrew a second litre. All went well and the patient recovered as if by magic. But six months later he again came under my care with symptoms of meningitis, and died in a few days. At the post-mortem we noted the disappearance of the pleurisy—there only remained a few pleural adhesions, but we found tuberculous meningitis with granulations in the lungs.

In his anatomical and experimental researches on tuberculosis of the pleura, Dr. Peron comes to the following conclusions: “The pleurisy called pleurisy *a frigore*, is of tuberculous origin in the great majority of cases; it is due to tuberculous infection, possibly latent, of the pleura.” As you see, the anatomopathological researches are in favour of the tuberculous nature of a *frigore* frankly acute pleurisy.

In many cases clinical observation confirms the results of pathological anatomy, by showing that a large number of patients suffering from an apparently primary and frank pleurisy are in reality at the same time tuberculous, since, even when they recover from their pleurisy, the tuberculous infection a few months or years later invades their lungs, meninges, peritoneum, or other regions of the organism. It is evident that in these subjects the pleurisy was but a more or less precocious localisation of the bacillary infection. But clinical observation also teaches us that there are other patients who may recover from frankly acute pleurisy, without there remaining the slightest trace of tuberculosis, and the patient may live for ten or twenty years free from any tuberculous manifestations.

Ample statistics are available on this point; Fiedler records 92 pleuritic persons attacked by sero-fibrinous pleurisy, whom he punctured. Of this number 17 died tuberculous at the hospital, 8 succumbed to
tuberculosis after leaving hospital, 66 left hospital tuberculous or suspected of tuberculosis, and 21 were in good health at least a year later. The statistics of Messrs. Bars and Bowditch in England, and MM. Mayor and Ricchoen in France, furnished results which are not discordant, yet the tuberculous element occurs in 10 to 15 per cent. of cases. At the meeting of the British Medical Association held in Paris last year, Dr. Vergely furnished me with four observations of pleuritic persons who had been aspirated fifteen, twenty, and twenty-two years previously, and their lungs, peritoneum, and pleura were in excellent condition, and they were enjoying good health.

Dr. Lépine reported half a dozen cases of pleurisy which had been under observation for many years, and which had not been followed by tuberculous manifestations. Dr. Corvisier has published a work in which he records the mildness of numerous cases of pleurisy which he has observed during a period of twenty-five years and which he had been enabled to follow for a long time. M. Dreyfus-Brisac had also known patients who had continued in good health after having recovered from acute pleurisy.

Since my first works on thoracentesis by aspiration, which date more than thirty years back, I have aspirated a large number of pleurises. I lost sight of nearly all the original cases, and I was unable to follow up a few patients, and I can recall eleven cases of persons attacked by frankly acute pleurisy, aspirated by me, who recovered without there having appeared the slightest tuberculous manifestations.

I owe to Dr. Lamarre (St. Germain) the history of a very interesting case.

A certain wall served as a resting place for soldiers carrying on their back 50 kilogrammes of straw or corn; while in perspiration they leaned against the wall in such a manner as to rest their burden on top of the wall. An epidemic of a frigore acute pleurisy broke out in the regiment, from which the civil population was exempt. All these pleurises were on the same side, and they healed well, with or without aspiration. Dr. Lamarre formed the opinion that they were cases of pleurisy a frigore. The corner of the chateau where the men rested while perspiring was protected against winds excepting from the north-east, which was at times very cold, and this wind impinged on the men’s right sides. At the request of Dr. Lamarre the colonel forbade the men resting in that dangerous spot, and no further cases of pleurisy occurred. But the guard regiments changed, but six months, and in the newly-arrived regiment the same cause again gave rise to pleurises; it was again necessary to prohibit men from resting against the wall. This experience (for the occurrence again occurred) was renewed with the same regularity on several occasions. This infectious resting place gave rise to fifty cases of pleurisy, without, however, a single fatal result. In addition to these facts Dr. L. had in his medical practice for thirty years twenty pleurises which disappeared without leaving the slightest tuberculous trace.

Referring only to clinical cases, we see that recovery from frankly acute pleurisy without the slightest tuberculous trace remaining is not so very rare. These cases militate in favour of the existence of a frigore acute pleurisy.

Dr. Trasbot, in an interesting communication to the Academy of Medicine, demonstrated that a pleurisy was in course in the horse, dog, and sheep, and that in animals it could have nothing in common with tuberculosis. In support of this opinion he mentioned the following cases. In 1871, in a regiment, some newly-recruited cuirassiers had clipped their horses, which slept in the open air, often without any covering. In a few weeks there occurred amongst these animals thirty cases of pleurisy, nearly all fatal or almost fatal. Dr. Duviersart had 160 cases of pleurisy, 60 of which were fatal, in a flock of 400 sheep which had just been shorn during a very cold February. Dr. Rousseau has observed very strong healthy dogs attacked by pleurisy after jumping into a lake and stag.

According to Dr. Trasbot, "The three domestic species, the horse, dog, and sheep, in whom pleurisy is most often met with, are precisely those who are the most rarely tuberculous. Thus the result of the personal observation anteriorly mentioned is in formal contradiction to the opinion that the pleurisy of these species may be a variety of tuberculosis. Moreover, this fact, which reveals itself with such perfect evidence from clinical sources, is absolutely confirmed by experiment. We have succeeded in infusing the guinea-pig or rabbit with tuberculosis by injecting the sero-fibrinous pleurisy of a horse or dog. I myself did it on numerous occasions, injecting the liquid into the pleura, lung, peritoneum, and pleura, and the results from this point of view were invariably negative. It is, therefore, undeniable that non-tuberculous a frigore pleurisy is of frequent occurrence in animals. This extract from veterinary medicine is of importance of a chill in provoking pleurisy in animals; but let us restrict ourselves to human beings, and let us once more raise the question. Does there occur in man a real a frigore pleurisy which is non-tuberculous, and if so, in what respect does it differ from tuberculosis?"

In endeavouring to reply to this question we invoked the numerous resources of the laboratory. It was thought that the inoculation of the pleuritic liquid into the peritoneum of guinea-pigs would furnish valuable information. MM. Chaffard and Gombault obtained thus 50 per cent. positive results. The inoculations practised by M. Nettier with the exudation of fibrinous pleurisy, in appearance, essential to frigore, furnished eight positive results in 20 cases, or 40 per cent. The same author has published a further series comprising 14 cases of pleurisy, of which two were apparently primary. Of the 12 cases of pleurisy in guinea-pigs, infected the guinea-pig with tuberculosis. When the peritoneum of the guinea-pig is inoculated, not with a small dose of pleural liquid, but a dose of 20 cc., as was done by MM. Péron and Le Damany, the chances of success are greater; nevertheless, so far we have had rather a large number of failures.

In short, the method of inoculation furnishes valuable information, but, in a rather large number of cases, it leaves the tuberculous or non-tuberculous nature of the pleurisy in doubt; the value of inoculation is absolute when the result is positive, but a negative result does not prove the pleurisy to be non-tuberculous. It is admitted that a clearly tuberculous pleurisy may give negative results from the injection of pleural liquid; the effusion may be far from virulent and the bacilli may be scattered in the pleural liquid to such a degree of dilution that they may elude the peritoneum of the animal a few micro-organisms which are promptly destroyed.

Injections of tuberculin furnish information of incontestable value. According to the official returns from Prussia, patients attacked by pleurisy show no appearance, but in reality tuberculous, are as susceptible to tuberculin injections as frankly tuberculous patients. But the injection of tuberculin, even when handled prudently, is by no means free from danger. Many precautions must be taken. First of all the patient must be completely afebrile. If the rectal temperature of the patient, says M. Landousy, taken four times in the twenty-four hours, shows absolute afebrility, and only in such cases, the action of tuberculin may be tried. A subject suffering from acute pleurisy is more or less feverish, and does not, therefore, fulfill the requisite condition for the injection of tuberculin. The quantity of tuberculin to be injected varies from a tenth to a quarter of a milligramme, diluted with sterilised water; if the patient is tuberculous, the febrile reaction and increase in temperature commence from twelve to twenty-four hours after the injection. But it may be that the dose injected is too small to provoke in a certain individual the expected reaction; moreover, a slight reaction may occur whenever tuberculosis is absent. A few words should be given occasion to make injections of tuberculin in very small doses and the result was far from satisfactory: one of my patients had perforation of the tympanum, another an outburst of lung trouble. I have not employed it since then.

The application of the method of cultures to the researches for the tuberculous bacillus in effusions has
not been successfully practised until quite recently. To obtain positive results, it was necessary to have a very favourable culture medium. This medium is glycerinated gelose blood. By the admixture of gelose with the blood of a rabbit we obtain a culture surface on which the microbes, which do not grow on the usual media, grow readily enough.

The culture which I am about to bring before your notice was obtained by inoculation of the pleural liquid of one of our patients in the St. Christopher Ward; the tuberculous colonies appeared on the twenty-sixth day. In two other cases, MM. Bezançon and Griffon had sown in tubes of gelose blood the liquid of acute pleuritis occurring under Dr. Chauffard and, after twenty-eight days, there appeared tuberculous colonies of the size of a pin’s head.

You can see what service the culture of Koch’s bacillus may render in connection with the diagnosis of tuberculous effusions of the pleura. It would be the best method if only it were more trustworthy. At the present time this method of procedure, in spite of its value, does not solve the problem with sufficient uniformity; it is, however, an excellent means of control and it is easy to apply.

Then as to the method of sereo-diagnosis? In a sereo-diagnosis presupposes two factors, whether it is typhoid pneumonia, or tuberculous infection; on the one hand, we must have a homogeneous culture in a liquid medium in which the microbes exist separately; on the other hand, we must have the serum of the injected patient. The mixture of which the culture provokes the agglutination of the microbes.

In 1886, M. Arloing put himself to the task and sought a sereo-diagnosis for tuberculous similarity to the sereo-diagnosis of M. Widal for typhoid fever. The problem was solved by M. Arloing when he discovered the means of obtaining homogeneous culture of the bacillus in a liquid medium.

To use the conditions most favourable, it is necessary to use a culture of tuberculous bacilli, twelve days old. A small quantity of culture is placed in a tube of minimum dimensions and of small calibre. This culture is mixed with the serum obtained by prickling the pulp of the finger. The mixture is made in the proportion of one part of serum to 5, 10, or 20 parts of the culture medium. If the result is positive the phenomenon of agglutination may be observed, after a lapse of time varying from one to five hours. The upper layers of the mixture become clear, whilst the lower part of the tube gets thick with flakes, which give it a clouded appearance, in striking contrast with the transparency of the upper layers; microscopical examination confirms the result of the agglutination and Koch’s bacilli appear gathered together in masses, instead of being isolated.

The sereo-diagnosis of tuberculosis is certainly of service when the clinical diagnosis is doubtful or impossible; MM. Arloing and Courmont gave numerous examples to prove this. There are cases of pulmonary tuberculosis which appear in an almost latent condition, and which, for a time, escape ordinary methods of investigation; the diagnosis of tuberculous peritonitis associated with ascites is often uncertain; tuberculosis of the bones and articulations is the more difficult to diagnose since it may appear under the guise of the multiple forms of acute arthritis, dry arthritis, deforming and chronic arthritis; it may even appear as a particular rheumatism when it is really a tuberculous pseudo-rheumatism (Poncet). Under similar circumstances the sereo-diagnosis has often enabled us to show the tuberculous nature of lesions and lead to remedy errors in diagnosis.

(To be continued.)

A case of
TRIGEMINAL NEURALGIA
AND EXCISION OF THE
GASSERIAN GANGLION.

By T. E. GORDON, M.B., F.R.C.S.I.,
Surgeon to the Adelaide Hospital, Dublin.

An operation for the removal of the Gasserian ganglion has not, as far as I know, been previously reported at the Academy. It is an operation possessing many points of interest and difficulty. These things being so, I need not apologize for asking your attention to the history of the present case.

History of Case before Operation.

The patient was first attended by Dr. Cope, who sent her to the Adelaide Hospital to be under the care of Dr. Wallace Beatty.

The following is Dr. Beatty’s account of the case:

Mrs. R., aged 63, is a small, delicate-looking woman. Her family history revealed nothing of importance. She said she had always been of a nervous temperament, and had in her life much worry and anxiety. The first attack of neuralgia came 2 years before the operation. On the day she was coming downstairs, and made her shriek with pain. It lasted a few minutes. It began in the left side of the upper lip and cheek, and spread to the temple. Its character was as if a knitting-needle was bored into her left temple and turned round. The second attack occurred on the following day. Fresh attacks followed; at first there might be weeks interval between them. Her paroxysms; she noticed that they were not so frequent in the summer-time till this year. At present the attacks are very violent an frequent, coming on every ten minutes or so, and lasting about a minute or a fraction of this time, and they usually begin in the left side of the head, the temporal and fore parts of the parietal regions, but sometimes in the face. The paroxysms are most severe at night, giving her fearful nightmares and waking her. The pain was on one occasion so severe and maddening that she attempted to kill herself with a razor, and was only prevented by her daughter coming into the room and snatching her in the act of suicide. The patient was in a pitiable state when she presented herself for admission to the hospital. She was some weeks in the hospital before surgical treatment was adopted. During this time she had to be repeatedly given hypodermic injections of morphone.

The paroxysms of pain were excited in many ways, in addition to coming on spontaneously. Thus, moving of the jaws in mastication, the effort of speaking, the entrance of a person into the ward, brought on a paroxysm. All the branches of the left trigeminal nerve seem to have been affected from time to time, except the lingual. At one time, when pain was severe, she noticed an increase of saliva, but no pronounced symptom. Tears would flow occasionally from the left eye. Tender points were present in different places. All her teeth had been extracted without relief. There was no anaesthesia. Taste was normal. The heart and lungs were normal. There was a little albumin in the urine, but no tubercosis. The pulse was of low tension—about 80. She told me the only cure was to kill her.
This is a sketch of her past condition up to the time I handed her over to Mr. Gordon. This case may be regarded as a typical example of major trigeminal neuralgia. The woman in the later period of middle life, the almost sudden and severe nature of the symptoms of pain, were first separated by considerable intervals, but later occurring every day, and in response to the most trifling stimuli, all her teeth extracted in the vain hope of relief, her life made scarcely endurable by hypodermic injections of morphia; in all this the patient but repeats the history of other cases of this particular disease. Not the torrential aspect of these cases is the absence of any tendency of the disease to shorten life. As the pain becomes greater and frequent almost to be continuous, the patient resorts to increasing doses of hypnotics, and as a result of this and the prolonged suffering, develops a melancholic insanity, or obtains in suicide a relief from the sufferings. I hope you will not think the picture overdrawn; the present case is, as I have said, but a repetition of the history of many others, and if any think the description an exaggeration they have not met with the disease under consideration, and they are not in a position to discuss the ethics of the operation for its cure. I beg to stress the fact that we have some relief, but it is almost certain to fail in the end, and so the case comes under the care of a surgeon. It is unnecessary to draw attention to all the operations performed for the cure of this disease. I think the majority of surgeons are satisfied that all ordinary neurotomy is likely to fail. The pain disappears, of course, after the neurotomy, but generally returns in from 6 months to three years. It is rather more than ten years since Horsley for the first time excised the Gasserian ganglion. This operation is now regarded by many as the only operation to be recommended in cases of true major neuralgia of the fifth nerve. Before describing the steps of the operation, let me as briefly as possible, recall to your mind the general anatomy of this nerve.

**Anatomy of the Fifth Nerve.** — In a dissection of the middle cranial fossa, the Gasserian ganglion is found lying near the apex of the petrous bone. Its large sensory root is seen entering this region under the margin of the tentorium cerebelli, and ending in the ganglion. Springing from the front of the ganglion we find the three main divisions of the nerve. The first of these divisions, the ophthalmic, lies most internal, and passes to its distribution through the spenoideal fissure. This distribution includes the eyeball and the skin of the nose, and the mucous membrane of the nose and roof of the mouth, this nerve, it is of special interest to remember, supplies the teeth of the upper jaw. The third, or inferior maxillary division, leaving the cranium by way of the foramen ovale, supplies the lower teeth. Tri-facial neuralgia probably never originates in the area of the ophthalmic division, and this is significant, relative to the pathology of the affection, for this division alone has no part in supplying the teeth of either jaw. The inferior division has also within its area the musculo-cutaneous membrane of the floor of the mouth and the tongue and a wide cutaneous area (auriculo-temporal). The lingual branch has a special interest, seeing that it carries within it the fibres of the chorda tympani, the nerve of taste for the front of the tongue. I may further remind you of the motor element in this third division, for the supply of the muscles of mastication. It is remarkable how slight is the inconvenience caused by destruction of this motor nerve.

If we follow the large sensory root under the tentorium into the posterior fossa of the skull it will be seen to pass to its, so-called, superficial origin, at the side of the pons. In transverse sections of the pons, the sensory spiral seen traversing the fibres of the middle cerebellar peduncle to reach its nucleus, which is placed outside that of the motor root. The greater part of the sensory root does not, however, end here, but passes downwards, and can still be clearly seen in sections where the decussating pyramids show that the level is near the lower end of the medulla. I think it is most important — and from our present point of view — to bear in mind that the term origin is misleading. In a Golgi preparation the fibres of this spinal root of the fifth nerve will be seen to end as free arborisations about the cells of the nucleus, but to be in no sense processes of these cells. This nucleus is, then, to be regarded rather as the end than the origin of the nerve. The fibres to which the cells do give origin belong to a higher system, and may be seen (in such a Golgi preparation as we are speaking of) sweeping across the medulla to reach a cortical path on the opposite side of the raphé. To find the true origin of the sensory fibres of the fifth nerve we must, in the case of the posterior spinal roots, look outside the central nervous axis, and we have it in the Gasserian ganglion, which is the homologue of the ganglion of the posterior nerve root. The cells of this Gasserian ganglion are the genetic origins of the fibres, and they are also the trophic centre, for it has been shown that if the ganglion be destroyed all the fibres degenerate both peripherally and centrally: the nerve is blotted out of existence. Now, in this we have the theoretical basis of the operation we are about to consider. If recurrence of pain after neurotomy is due to regeneration of nerve fibres, excision of the ganglion will make such regeneration impossible, and cure ought to be permanent. Should recurrence occur under such circumstances it must be due to disease involving those higher centres which we casually noticed a moment ago. Horsley and Krause, both writing recently, state that so far they have had no case of return of neuralgia after complete excision of the ganglion.

**The Operation.**

The operation I elected to perform is that known as the Hartley-Krause operation. In this an opening is made in the temporal region of the skull: the brain and dura mater are together raised from the floor of the cranium as far as the point of exit of the second and third divisions of the fifth nerve; the space of Meckel is opened, thus exposing nerves and ganglion; finally, the nerves are divided, and the ganglion with its large sensory root removed. We may conveniently recognise four stages in the operation. In the first stage a large flap is turned down, more or less horse-shoe shaped, and including a large part of the temporal muscle. An opening is then made in the skull with a medium-sized
trephine, and this opening is enlarged as much as necessary with some form of forceps or rongeur (I used Horsley’s prismatic bone forceps). The removal of bone should be ample, and in particular the bone should be clipped away well down to the base of the mid-cranial fossa. The attempt to preserve a bone flap is inadvisable, for it prevents the exposure, and has been shown to be unnecessary. I had some difficulty in this stage of my operation, owing to the presence of a bony canal for the middle meningeal artery in the fore part of the trephine area. The artery was necessarily torn, but the bleeding was easily arrested by a plug of Horsley’s aseptic wax.

In the second stage the dura is raised from the middle cranial fossa as far as the points of exit of the two lower divisions of the nerve. One knows when these points are reached by recognising two points of fixation of the dura. These constitute an important guide. That which demands all attention during this stage is haemorrhage—more or less profuse, continuous venous oozing which is obstinate. On the experience of some this bleeding has proved uncontrollable, and it has been necessary to postpone the subsequent steps of the operation for several days, leaving meantime a gauze plug in the wound. Such experience is fortunately exceptional. As a rule a sanguinous oozing with sterile pledges of gauze and plunging of the fundus (particularly the foramen spinosum and foramen ovale) suffice to arrest the haemorrhage. One naturally thinks here of a preliminary ligature of the external carotid artery. Horsley is emphatic in condemning this as a routine practice, and, as a matter of fact, plugging the foramen spinosum (thus controlling the vascular area of the middle meningeal artery and plunging the foramen ovale (which will arrest the venous regurgitant bleeding from the pterygoid plexus) will do all that ligature of the external carotid could do. This ligature obviously could not influence bleeding from torm tributaries of the cavernous sinus.

The third stage includes the opening up of Meckel’s cave and the complete exposure of nerves and ganglion. This space is opened by an incision through the dura, just where the nerves are leaving the skull, and by a division of the arch of dura which passes from one of these openings to the other. Before discussing the details of this stage, I wish to draw attention to certain anatomical relations. The Cerebriform ganglion lies, as we have seen, at the apex of the petrous bone. The bone underlying it is extremely thin, and there may, indeed, be only a layer of fibrous tissue separating the ganglion from the internal carotid artery. On the inner side the sixth nerve is a specially close relation and has often been accidentally injured. The very intimate relation of the cavernous sinus to the ganglion and the ophthalmic division is well seen in a coronal section of a frozen head. The same section gives an idea of the depth at which the ganglion is placed, and thus shows to what extent the brain must be retracted during the progress of the operation. The knowledge of the position of the foramen spinosum is important, for it may be necessary to plug it when the field of operation is obscured in blood. It generally lies about half an inch behind and to the outer side of the foramen ovale.

We now return to the operation, and suppose the space of Meckel opened and ganglion and nerves exposed. The middle meningeal artery is not necessarily divided during this stage, but on the whole it seems better to do so, with a view to getting as much room as possible. At this point it is necessary to decide whether one will remove the whole ganglion with the sensory root or merely tear away the outer part, which belongs to the second and divisions. I only removed the outer part, but I shall, in future, endeavour to effect a complete excision, notwithstanding extra risk, in order to insure against recurrence of the neuralgia. To expose the ganglion for this complete excision it is important, as Cushing has indicated, to divide a fibrous layer which remains covering the ganglion after the general reflection of dura has been accomplished. This being done, one must next free the ganglion from its surroundings, beginning on the outer side.

This brings us to the fourth and final stage of the operation, in which the nerves are divided close to their points of exit from the skull, and then freed by careful blunt dissection up to the ganglion. It is, in this latter case, essential that the evulsion is properly done, the sensory root will probably tear away from the side of the pons. In carrying out these steps of the operation the cavernous sinus is ever before the operator’s mind, and it is very liable to injury despite all care. It is, however, satisfactory to know that in those cases where the sinus has been injured, the haemorrhage has been readily controlled by pressure, and no ultimate harm has resulted. A fear of sloughing of the cornea need not deter one from performing this complete operation. It is quite a rare complication, and when it does occur it is not due to mere cutting off of nervous connections. This has been definitely proved by experiments. This unfortunate sequel is due to irritation, and implies generally a basal meningitis, or, in other words, sepsis.

Finally, the plugs are removed, and the wound closed, but with a drain at its lower part.

I have given an account of what I believe to be the more important features of this operation. It is obviously an operation attended with much difficulty—difficulty, however, which can to a great extent be met by the first instance an accurate knowledge of the anatomy of the middle cranial fossa. It is equally apparent that there are dangers attending it, and here it is encouraging to learn the low mortality of the operation in the experience of Horsley and Krause. Horsely, in 1901, recorded twenty-two operations with only two deaths. Krause, in the same year, gave the results of twenty-five excisions of the ganglion with three deaths.

In some cases there have occurred after-symptoms of brain injury, such as aphasia and ocular palsies, resulting from accidental nerve lesions, but these have generally been transient only. In the case of my patient there occurred a partial third nerve paralysis, which disappeared in a short time. I saw this patient recently (about eight months after the operation) and found her in good health, and entirely free from her neuralgia. The scar is very slight, and the hair, having grown, conceals the depression.

In conclusion, let me ask you, before giving expression to an opinion on the merits of the operation, to bear in mind the gravity of the disease for which it is undertaken—the pain of maximum severity—the intervals of freedom.
becoming progressively shorter until in the end the suffering is continuous. Further, remember that, with no hope of natural cure, there is a strong tendency to melancholic insanity, and attempted suicide is so frequent as to be given by Krause as one of the symptoms of the disease.

On the other hand, remember that, if the operation is successfully performed, there is every reason to believe that the cure will be permanent.

I must not omit to express my indebtedness to Sir Victor Horsley for having given me the great advantage of seeing him perform this operation, and for advice regarding instruments and other things.

WIDAL'S SERUM REACTION IN INFANCY. (2)

By Dr. A. JOSIAS and Dr. L. TOLLEMER

[Specialiy translated for The Medical Press and Circular.]

Since Widal demonstrated the phenomena of serum agglutination, on June 26th, 1896, at the meeting of the Société des Hôpitaux de Paris, his diagnostic sign has become generally recognised as one of the most trustworthy signs of typhoid fever. Although the value of M. Widal's discovery was generally recognised in the cases of adults, many distinguished authorities did not think it had any diagnostic value in the case of children; among these were M. Haushalter, M. Couture ("Thése sur la Fièvre typhoide de l'Enfant," 1897), Kasel (Würzburg, 1899), Pfautler ("Jahrbuch für Kinderheilkunde," 1899); M. Martin ("Sommaire médicaux," 1900), in a clinical lecture, pronounced the serum diagnostic agglutination test to be of no value, "in that it is not found until after the fifteenth day, and even then it is not well marked." This opinion was also pronounced by M. Rosenthal, at the Société de Pédriatric de Paris, on March 13th, 1900, who dwelt on the slowness of the occurrence of the serum agglutination test in typhoid; this opinion was, however, combated by M. Cluc, at the meeting on April 14th, 1900, who reported that in sixteen cases of typhoid fever he obtained the serum reaction of Widal in each case on the eighth day of the disease. Finally, M. Masbrenier, in his inaugural thesis, confirmed the statement of M. Cluc, and demonstrated that the child's serum gives the test as readily as that of the adult. Thus we possess in this obscure disease of children the same valuable test that we find so useful in the case of adults. We have made systematic investigations on the serum reaction test in all our cases of typhoid fever in infants, and in all suspected cases. We have produced the reaction in fifty cases of typhoid fever with the serum of Chantemesse; the serum reaction was positive forty-nine times; it only failed once—in the case of a child fourteen years old; she gave negative results on the tenth day of the sickness, and we did not get a further opportunity of examining her blood. In our experiments on the agglutination of the Eberth bacillus by serum we added one drop of emulsion of bacilli of Eberth, very quick and agglutinating readily; the culture was always of twenty-four hours' standing. The mixture was preserved in an absolutely aseptic glass, which was covered by an aseptic glass cover, thus permitting of examination without any risk of contamination. In doubtful cases we diluted the mixture to one-twentieth, and even to one-fiftieth. About every ten minutes we took up with a pipette a few drops of the emulsion from the bottom of the glass for examination on a glass slide, in a little cell made by placing on the glass a triangle of fine platinum, dipped in vaselin and covered with a fine slide. This little plan allowed of many examinations without many apparatus. We could then easily recognise the identity of the bacilli and the formaion of agglutinative masses. We looked on the reaction as positive when the agglutination occurred immediately in small and numerous masses, becoming larger and more numerous. In prolonged examinations we found the serum reaction always well marked. We thus formed for ourselves a measure of the agglutinative power by the rapidity with which the mass was formed.

In the great majority of cases this agglutination took place quickly, and was clearly seen in a lapse of time varying from a few minutes to an hour. In doubtful cases we prolonged the contact during twenty-four hours, but we took no count of any exceeding that time, that is, of those which formed no agglutinative mass. If the agglutination took place in twenty-four hours we again tested a fresh quantity of serum, and found if a marked and positive result was obtainable with a dilution, which sometimes took place in two hours. The dilution of one-fiftieth and one-hundredth eliminated many sources of error, and was only used for laboratoy work, and not unfrequently enabled us to get our results within a comparatively short time. We classify our fifty cases into two groups. In the first we group all those in whom the reaction was marked on their entrance into hospital; in the second class we group those in whom we had to repeat our examination before obtaining Widal's serum agglutination test. We report above one case in which no reaction was obtained.

Agglutination.

We may remark that the blood was drawn from the child on the day of admission, hence the figures are not absolutely correct in some instances; it constantly followed that the reaction was positive in many cases on the day of admission. In a good number of cases the reaction was very marked many days after their being first examined. The second group, those in whom the reaction was slowly developed, were but five. The positive reaction occurred on the tenth, fourteenth, eighteenth, twenty-first, and thirtieth day after infection. The first case was

* Paper read at the International Medical Congress at Madrid.
that of M. M., aged 45, who was admitted on March 4th, 1902, on the tenth day of her sickness; the serum test gave negative results until March 8th, the fourteenth day, in a dilution of one in a hundred in less than an hour. The second case, C. S., aged 83, entered hospital on March 11th, 1902; ten times the serum test gave negative results; it was not until March 28th, the twenty-first day of the sickness, that it was strongly marked on April 18th. The third case was that of P., aged 15. He was admitted to hospital on April 12th, 1902, on the sixth day of his illness, and for twenty-two days the serum test gave negative results; on May 6th, the thirteenth day of the fever, the serum reaction was positive. C. C., aged 14, the fourth case, was admitted on August 17th, 1902, on the fourth day of her illness. The serum test gave negative results daily until August 23rd, when feeble agglutination was noticeable, and it became strongly marked on the 25th of the same month. D. G., aged 14, the fifth case, was admitted on September 6th, the eight day of his illness. On September 16th, the eighteenth day of the fever, a slight positive reaction was noticed with the serum test. In this short study of the Widal reaction in children, it may be noticed that it is subject to the same variations that we find in the adult. It appears in different periods of the fever. It was, in fact, one of the cases in which the serum test gives a positive reaction before the tenth day of the fever in children. The presence or absence of the reaction in the early stage of the disease does not seem to bear any correlation to the severity of the fever. We have not seen the more marked agglutinative power of the serum in children over eight years of age which some authors claim to have seen. Kasel, with Pfundt, holds that the serum agglutination is very mild prior to the eighth year; but our observations go to show that prior to eight years the serum reaction is intense. In four of our cases of retarded reaction the patients were over fourteen years of age, patients in whom the fever closely resembled the disease in adults. The reaction in Widal has a considerable value in children as in adults. It would be absurd to speak of the reaction as being generally slow in appearance in the serum of the fever of children, when we found it slow in appearing in five cases out of fifty. All that we can say is that it is more slow in the time of its appearance in children than in adults. Ransome, in his excellent theses, tells that he found the serum reaction slow of appearance in two adult patients in eighty-three adults. We would finally draw attention to an important point in the character of the agglutinative property. The injection of the anti-typhoid serum of Chantemesse in no way affects the agglutinative properties of the blood. The serum reaction is produced independently of the injection, whether it be injected before or after the application of the test of Widal. There are some exceptional cases in which the serum reaction has been delayed without our being able to offer an explanation.

THE PATHOLOGY OF GENERAL PARALYSIS OF THE INSANE.

By W. FORD ROBERTSON, M.D.Ed.,
Pathologist to the Scottish Asylums Board.

The speaker contended that the essentially syphilitic origin of the disease had never been proved. The most important fact against this hypothesis was, in his opinion, that only a very small proportion of syphilis even of the general paralytics or tabetics. That syphilis strongly predisposed to the subsequent development of general paralysis was, however, beyond question. He maintained that there was evidence that in this disease they were dealing with an active bacterial toxæmia. There was a toxic bacterial infection from the alimentary tract. This, however, was not special to general paralysis. It occurred in various forms and degrees in other diseases. There was something added in general paralysis, giving the disease its distinctive characters. On the ground of their recent observations, his colleagues and himself had advanced the hypothesis that the special factor consisted in the pathogenetic action of a bacillus identical in morphological and cultural characters with the Klebs-Löffler bacillus. The phenomena of general paralysis presented to the pathologist a problem in disorder of the natural immunity and its consequences. All the recognised etiological factors of general paralysis were such as were known either to make an excessive drain upon the lymphatic functions of the bone marrow or directly to injure this tissue. Before the development of general paralysis the patient had reached a condition of myelocytic insufficiency. The consequence was that the saprophytic bacteria of the alimentary and respiratory tracts infected to assume a pathogenic and septic form, any change in themselves, but because the forces by which they were normally combated had become weakened. There was added the special toxic infection to which he had referred. There were grounds for believing that local lesions, especially in the upper portions of the respiratory and alimentary tracts, played an important part in initiating and maintaining the special infection. Various bacterial toxins were absorbed producing the phenomena of the disease. He then summarised the evidence in support of the hypothesis. The bone marrow of the general paralytic presented chronic morbid changes of a characterised by the rises of temperature, leucopenia, disorders of the digestive functions, chronic sore throat, septic condition of the mouth, and frequently obtainable evidence of chronic bronchitis constituted clinical evidence pointing to a bacterial toxæmia of the kind indicated. There were severe chronic changes in the alimentary and respiratory tracts of the character of those that were produced by the prolonged action of bacterial toxins. There was direct evidence of general excessive development of saprophytic bacteria in the alimentary tract. There was evidence of the almost constant presence in the alimentary and alimentary tracts of a bacillus resembling the Klebs-Löffler bacillus. It could
readily be isolated from the nasal cavities during life. There was evidence that this diphtheroid bacillus occasionally took part in a terminal blood invasion in cases of general paralysis. A filamentous organism very frequently present in enormous numbers in the lymphatics of the alimentary tract, and there were strong grounds for thinking that it might be a thread form of the diphtheroid bacillus. The evidence upon this point, however, was not conclusive. The experimental investigation was still in progress, but evidence had already been obtained showing that when rats were fed with unsterilised broth cultures of this organism a fatal disease was produced in which the nervous system was specially involved. The morbid changes were in many respects similar to those that occurred in general paralysis. No claim was made that the hypothesis had been established. He had merely stated a series of facts which, he claimed, harmonised with it. Experimental investigation would alone determine whether it was to be retained or rejected.

**Clinical Records.**

**CASE OF ANEURYSM OF THE ARCH OF THE AORTA.**

BY GEORGE RANKIN, M.D., F.R.C.P.,
Physician to the "Dreadnought" Hospital, Greenwich, &c.

JOHN McC——, fireman, aged 35, admitted on April 1st, 1902, for pain in the chest, with a pulsating tumour in the median line about the level of the second and third costal cartilages.

He had noticed the pain for about five months. It first interfered with his doing his work at St. Helena in November, 1901, on the outward voyage to the Cape. On arrival at Port Elizabeth he had to go into hospital on account of constant pain and dyspnoea. Since then he had not been fit for any work, and latterly had been unable to sleep at nights except for short naps, and then only if propped up in bed. The pain radiated down both arms, but was most severe on the right side. He had a definite history of syphilis contracted fourteen years ago. He was addicted to alcohol, and admitted that during the few weeks he had been ashore he had been drinking very heavily.

**Condition on Admission.**—The patient was a well-built and well-nourished man. He complained of constant, dull, heavy pain and distress in his chest, more marked on exertion. He was breathless, and quite unable to lie down in bed on account of dyspnoea. The pulse was regular and of medium tension. The right radial was stronger than the left radial pulse.

**Temperature 98°8; respiration 24 per minute.**

On inspection, in the middle line of the chest, about the junction of the manubrium with the body of the sternum, there was a large, circular, pulsating swelling causing protraction of the bony and cartilaginous chest wall. The superficial diameter of the pulsating area was measured 5 ins. transversely and 3½ ins. vertically. The skin over the swelling was red, tense, and painful. The pulsation was synchronous with the heart-beats, and on palpation was markedly expansile. The note on percussion over the swelling was dull, and the act of percussion caused a considerable amount of pain. The cardiac impulse was seen in the fifth left intercostal space in the nipple line; it was diffused and heavy, no thrill detected. Over the cardiac impulse the first sound was impure, but on auscultation upwards towards the tumour the muffled sound acquired the character of a murmur. Over the tumour itself was heard a distinct systolic bruit, followed by a loud, accentuated second sound. There were 1 ness and throbbing in the vessels of the neck. Tracheal tugging was well marked. There was no notable impairment of the percussion note over the lungs, but on the right side, behind, the air-entry was diminished, and the respiratory murmur was high-pitched and almost hepatic in quality. Voice-sounds were normal. The total area of hepatic dulness measured vertically in the nipple line 4½ ins. There was a space of 2 ins. between the upper margin of hepatic dulness and the lower margin of the pulsating tumour, over which the percussion-note was clear. The pupils were large and equal; they reacted to light and accommodation. No alteration or impairment of movement of the vocal cords was noticed. Both patellar and plantar reflexes were normal.

**Progress and Treatment.**—After a week's rest in bed, during which the temperature varied between 97°6 and 99°, and the patient was always supported in the sitting position with a bed-rest. Gelatine injections were advised. His distress was so great that he readily acquiesced. He was kept on a light nutritious diet, the liquid constituents being strictly limited. Alcohol was entirely withheld. He was also ordered a mixture containing iodide of potassium, carbonate of ammonium, and cinchona.

The front and inner surfaces of the thighs were shaved, and the skin cleansed with antiseptics. The first injection contained only 15 grains of gelatine in about 30 cc. of saline solution, the solution having been sterilised on three separate occasions and raised to boiling-point just before using. All instruments—the needle (a large exploring one), the syringe (a glass syringe of 100 cc. capacity), and the glass bottle—were also carefully sterilised by boiling. The puncture was made through the skin of the inner aspect of the thigh, about two to three inches above the patella, and the solution was injected warm. After withdrawal of the needle a gauze and collodion dressing was applied, also a pad of antiseptic wool with bandage to prevent irritation of the skin by the clothes. The local swelling round the seat of puncture disappeared in about six hours. Every subsequent injection contained 30 grains of gelatine dissolved in 100 cc. of sterilised saline solution. The injections, to the number of twenty, were given twice a week into each leg alternately. The temperature frequently rose to 99° on the night of the injection, and on three occasions just exceeded 100°, but otherwise no abnormal symptoms ensued. Complete rest in bed throughout the treatment was insisted upon.

The pain gradually disappeared; the patient slept well at night, and was, after a short time, able to lie down flat. He expressed himself as getting daily better, and was always anxious to be up and about. After he was allowed to leave his bed his movements and exercise were gradually increased, and he asked for his discharge from the hospital on July 9th, 1902, saying he felt no trouble in him, except that the pulsation was very much diminished; there was no pain on palpation, nor on slight pressure over the tumour.

The patient was seen ten days after his discharge. He admitted that he had been drinking heavily while out of hospital, and had been detained in one of the London infirmaries two nights previously on account of alcoholic coma. He had some return of pain, but the signs were unaltered, and with a few days' rest in bed his pulse quieted down and the pain disappeared again. He had had no trouble at the site of injection on the thighs.

**Special Articles.**

**BRITISH SANATORIA FOR CONSUMPTION.—IX.**

[By our Special Medical Commissioner.]

**THE CROOKSBURY SANATORIUM.**

In the finest portion of that region of the Highlands of Surrey which lies south of the "Hog's Back" between Godalming, Farnham, and Haslemere, the well-known Crooksbury Sanatorium is situated. The site is peculiarly adapted for the needs of such an
institution for the care of the consumptive. It is rich in natural beauty, of good elevation, enjoys a pure bracing air, has a southerly slope with good fall, the soil is extremely porous, yet not dusty, abundant protection also is afforded against winds, and there are many acres of pines and heather. The climatic conditions are such a station probably is the best to be had in this country. Not only does the district admirably meet physical needs, but the outlook supplies elements of the greatest psychological value. The scenery east of the Leith and the Charterhouse to Hindhead and the Hampshire Hills, while to the north lie the Hog's Back and the Aldershott Hills. Pins-clad heights are seen on all sides. The sanatorium is so excellently placed on the ridge that not only does it enjoy peculiar advantages from its exceptional situation, but permits of the very convenient selection of walks on either the east or the west sides, according to the needs of the patients or the direction of the prevailing wind.

The sanatorium has been specially designed and built for its present purpose. It was opened in May, 1900. It has been recently enlarged and can now accommodate twenty patients and various additional improvements are being made. The rooms in each block are arranged in single rows with large French windows facing south and have been so constructed as to facilitate the hygienic conduct of the apartment; the angles being rounded, the walls are of brick, floors and ceilings washable. The furniture is peculiarly suited in every way to the special needs of the situation. The heating is by hot-water coils. The whole sanatorium is fitted with water closets.

The south or old block is placed in a particularly well-sheltered situation, and is closely surrounded by pines, large numbers of which have had to be cut down in order to afford the necessary lawns and pine avenues, through which distant views of much charm can now be obtained. There are twelve rooms all on the one floor and looking south, and served by a common corridor, behind which lies one of the most convenient dining-rooms conveniently placed in relation to the two-storey kitchen block. Lavatories, with needle-bath, etc., and earth-closets, are placed at either end of the corridor, protecting the patients forwards. A special feature of the bedroom is the excellent design of the rooms. The wooden fittings are with sloping roof and mirror door so placed as, if desired, to allow the patient when in bed to enjoy the reflection of the beautiful country through the window. The fixed, simple, and artistic tiled washing-stands are of a tiled washing-stand, and is therefore rather more bracing, and is intended for the strictly incipient and more distinctly convalescent cases. It is built in two storeys and from the upper rooms glorious views are obtained, including St. Martha's Church on the downs beyond Guildford, the Charterhouse Schools at Godalming, Pitch Hill adjacent to Leith Hill, the Devil's Jumps, and Hindhead with its Beacon and Oakshott hill overlooking Petersfield, together with miles of pine-clad hills and undulating heather-decked country.

Still to the north lies the very artistic and convenient medical director's house, which is in telephonic communication with the two blocks. The water supply is good and is brought a distance of some five miles. There is also a large storage tank for rainwater.

The grounds are very extensive and provided with over three miles of delightfully arranged paths of various gradients; and immediately surrounding the estate are many acres of open country and open parks. Farnham is the nearest town and is 3½ miles away, Aldershott is about 5 miles away, and Godalming 7 miles, so that patients are relieved from the irritation incident to residence in or near a crowded district.

The sanatorium is directed by Dr. F. Rufenacht Walters, whose work on "Sanatoria for Consumptives" is generally recognised as the authoritative English work on the subject. Dr. Walters is ably assisted by his wife. The permanent nursing staff includes two highly-trained nurses, who act under a trained nurse-matron.

The treatment is based upon the rational application of the so-called "Nordrach System"—absolutely pure air, both day and night, a sufficient food to ensure steady gain in weight; exercise, graduated according to each patient's condition; regulated rest in bed or on cane lounges; attention to general hygiene, constant medical supervision and maximal treatment where desirable. The medical director presides at each meal and exercises a controlling influence over every detail of the daily routine. Every effort appears to be made to keep the patients happy and contented.

It is interesting to note that the rooms are carefully disinfected after the departure of every patient.

We had the privilege of dining with the patients and found the dietary varied, abundant and well fitted to the needs of the cases. The Liegehalle system is not adopted. There are no verandahs, but blinds are provided for protection from sun and rain. Visitors are not encouraged, but friends of the patients often reside in the neighbourhood and are allowed admission at reasonable intervals.

The terms are from four and a half to five guineas according to the condition of the patient and the situation of the room occupied. The extra fees include special nurse if required, special invalids' diet; beverages, and medicines other than emergency doses.

The nearest railway stations are Farnham 34 miles on L.S.W.R., and Ash, 4 miles on S.E.R. A cab can always be obtained at the Farnham Station. The registered telegraphic address is "Sanatorium, Farnham."

[FROM OUR OWN CORRESPONDENT.]

At the Society of Charity Physicians, Hr. Menzer spoke on the Streptococcus Serum Treatment of Tuberculous Mixed Infection.

In the treatment of pulmonary tuberculosis, that by hetol indicated a distinct advance. The treatment by serum was not new; Marmorek's serum had been employed by Blumenthal, for example, but in principle was incorrect, and the selection of cases was rather arbitrary. As he explained the variety of the species of streptococcus he held that this was an indication for treatment. At the same time he did not consider his observation conclusive. He mostly observed a disappearance of the catarrh and improvement in the appetite. The mixed infection, even when no bacilli could be found, was of great importance. He observed the object of the serum treatment was, therefore, by the removal of the mixed infection to afford a favourable prognosis for the whole disease and to improve the general condition. The serum treatment was particularly useful in the first and second stages, and in the third when the conditions as to nourishment were favourable and the heart was sound. He generally injected every four, five to eight days in quantities of 0.5 to 4.0 ccc.; in acute streptococcus infection in larger and more frequent doses. The usual reaction appeared with ½ cc. in from four to six hours in the form of headache, cough and expectoration. This contained leucocytes, cocci and tubercle bacilli, the streptococcus temperature rose half a degree C. up to 35°C., returning to normal sometimes only after several days. Sometimes tubercle bacilli appeared for the first time in the expectoration. The number of white blood corpuscles, which was not influenced by normal horse serum, rose
after injection of streptococcus serum about 1,500 \(1^0\) 4,000 per cubic millimetre; any considerable reaction appeared during the early weeks only.

The radiographs then showed the twenty-two cases, and then Röntgen images which were taken by Professor Grumman. The total result was as follows:—Of eleven cases in the first stage eight were cured (period since treatment three and one-fifth month; average increase in weight twelve pounds); three considerably improved; one case in second stage improved; two improved through the case in the second stage improved; two others partially. The result, compared with that by the tuberculosis treatment, was not bad; but for a definite conclusion to be drawn the results of years of treatment would be necessary. He concluded that on the whole there was considerable improvement of the general conditions, the healing of instances brought to the same degree of concentration, the mass should always be uniform.

Perlsucht bacilli from seven sources were experimented with; and with six of these a typical, grave disease, generally ending fatally in two or three months, was set up.

These cultivations were made from nineteen cases, of which the lungs, partly from the spuata, and partly from the tissue, and only seven cases were made use of. If injection with these bacilli were made, infiltration took place at the point of inoculation, but distinctly smaller than when perlsucht was used, and after some time the part improved. There was no fever. The adjoining lymph glands swelled, but never to the size of a goose’s egg. If the animals were killed after four months, bacilli still living were found at the point of inoculation, the lymph glands were but little, if at all, enlarged, and contained at most small-encapsuled caseous patches. Tubercle was never found in the intestinal organs. Bacilli from various organs, bone, cavical glands, etc., were made use of, but the result was essentially the same. On the whole, however, the thirty-nine cases of human tuberculosis were employed. Of these, nineteen caused no effect whatever, nine small local patches, seven somewhat larger, which, however, never extended beyond the neighbouring glands. Only four cases coming from children, two with pulmonary tubercle of intestine, proved virulent. In two of the cases of tubercle of the intestine the discovery of it was accidental, the children dying from other causes. Thus only two of the thirty-nine cases proved pathogenic for cattle. He thought, therefore, that Koch was right in denying the importance of feeding in the spread of tuberculosis in the human subject.

[FROM OUR OWN CORRESPONDENT.]

Austria.

ULCUS VENTRICULI AND OPERATION.

At the Gesellschaft für Innere Medizin, Lichtenstern showed a case of ulcer ventriculi which he had treated by operation. The patient, aged 29, was taken ill on February 22nd, with all the phenomena of ulcer in the stomach accompanied with haemorrhage. Refusing to enter any immediate danger to life, palliative treatment was continued till April 16th, when a severe attack supervened that necessitated immediate action on the 15th, when the patient collapsed from an assumed perforation of the gastric organ. Laparotomy was performed, after narcotising with Schleich’s inhalation narcotic.

On opening the peritoneum a large quantity of green-coloured fluid welled up, while the prolapsed bowel was greatly injected and covered with clots of fibrin. The perforation, two centimetres wide, was about the middle of an ulcer situated on the smaller curvature near the cardiac end of the stomach. The opening was drawn together with two stages of silk sutures. Over this was placed a gauze saturated with iodiform; the lower part of the wound drained and the abdomen closed. A salt solution and camphor were applied subcutaneously. The subsequent course of the healing was without any eventful incident, and fourteen days later the patient was dismissed as cured.

BILATERAL EMPEMIA.

Lichtenstern had a female, aged 36, who was taken ill on February 18th, last year, for which an operation was performed for dextral empyema, as the plural cavity was quite filled except for a small portion of the apex. The next day, owing to the severe dyspnoea present, thoracotomy had to be performed under Schleich’s local anaesthesia; three litres of exudation were drained off, which relieved the dyspnoea. A few days later a severe cough commenced, with a purulent discharge in the spuata denoting lung perforation. The fever which ushered in the first attack had quite disappeared, but reappeared in the beginning of March in a remitting form till March 10th, when a severe rigor ensued, with great dyspnoea, and a temperature of 39° cent. The objective examination revealed a dulness on the left side extending above the angle of the scapula, and to relieve the dyspnoea a Fleurant trocar was used and a litre of exudation removed. On March 13th, the patient again became dyspnoeic and another litre was removed; but, the symptoms becoming more grave from the presence of cardiac symptoms, an opening was made into the left pleura after the Bülau method and three litres of exudation removed, which relieved the patient. In four weeks’ time after this operation both wounds were closed, the patient breathing quite freely, with only a few adhesions in the lower part of the left lung to indicate the severe inflammatory action that had previously taken place.

DETERMINATION OF SEX.

At the Phico-Medical meeting Schulze gave the members a history of his experiments on plants and animals with a view to determining sex in the organism at an early period of its existence, and concludes that the sex is dimorphic in the cell of both plant and animal life. He agrees with Nussbaum that the lower plants resemble the lower invertebrate, such as the hydra, etc. He is now convinced that neither the age of the parents nor their condition will determine the sex, nor will the feeding on albumen or other substances affect the alteration or direction of sex.
PARALYSIS OF THE VOCAL CORDS.

Schüller presented two cases of unilateral paralysis of the vocal cords in combination with the whole central symmetrical phenomena. The first was a female, aged 44, with left-sided paralysis of the uvula, left cord, localised areas of the face and neck over the cervical segments in isolated patches, which pointed to an intra-medullary morbidity located in the oblongata and probably extending along the left side of the cord; presumably syringobulbar origin.

The second case was also a female, aged 55, with right-sided recurrent paresis, and paresis in the region of the right plexus cervicalis inferior. The radiogram showed a swelling in the right upper mediatinum and probably an intrathoracic struma as the cause of the paresis.

These two cases, he thought, presented a clinical picture with many symptoms in common, yet differing in origin. The first has now all the symptoms of a syringo-bulbar origin, although the early symptoms were not so easily interpreted, as syringo-bulbar origin is presumed to follow syringo-myelia; but from the course of the symptoms one is inclined to believe in a reversal of this doctrine, commencing in the medulla and extending to the spinal cord. It is possible, however, from the rapidity of death, that a tumour may be the cause of this, as in the second case, but located here in some part of the medulla oblongata.

ARTERIOFIBROSIS.

Hofbauer showed a case of arterio-fibrosis in a young student, aged 17. The apex of the heart was felt in the first intercostal space outside the mammillary line, the cardiac dulness extending from this point to the third intercostal space. There was swelling bulging over the cardiac area and forcible pulsations that caused the whole thorax to quiver. The radial arteries, more particularly the left, had an enormous impulse, while the crural arteries seemed to have irregular thicknesses. The Röntgen rays showed an increase in the cardiac area, as well as a diffuse tubercular thickening in the thix of the left lung with calcification of the glands. The common causes of primary arterial hypertension were absent, such as nephritis, lead or mercurial poisoning, nor could any hereditary taint, such as syphilis, be traced. Failing any murmur, we must abandon any indulgence in beer, which the absence of fat in other parts of the body confirmed. The blood pressure was 160/90. The diagnosis of arteriofibrosis was made in view of the fact that the patient was an infant, 18 months old, who thrived well up to the eighth month, when developing ceased, and she became apathetic. In the ninth month spasms supervened on the arms, with marked hyperesthesia. The patient showed at the first glance the characteristic picture: bent head, stupid gaze, sluggish limbs, pupils slightly dilated, with sluggish reaction, spasms in the lower limbs, increased patellar reflex on both sides of the Babinski sign. Ophthalmoscopic examination showed at the site of the papilla a white spot and over the yellow spot a pink one. Pulse rate 140. Temperature normal.

On the subsequent three days temperature 38° 2', 38° 6', and 39° 5'. On the fourth day the child died.

Under the name of Home for Crippled Children, a new society has been formed in Budapest, with the object of alleviating the sufferings of such children, and on the other hand to save from their difficulties mothers compelled to work for a livelihood, and who are thereby unable to take sufficient care of their crippled children.

Dr. Liebermann Leo, Professor of Public Hygiene, has started a very salutary movement viz., he desires to organise public hygienic museums in the larger towns and cities of Hungary for the instruction of the people.
Continental Health Resorts.

VICHY THERMAL STATION.

Vichy is unquestionably the best known of the thermal stations and health resorts of Central France. The therapeutic effects of the waters from the State Springs have been known and appreciated from time immemorial, and, situated as it is in an extremely picturesque part of France, less than 250 miles from Paris, and easily reached by direct express train, the spa has always been largely patronised by the victims of certain diatheses. Oddly enough, it was, until recently, one of the few French waters with which I was not personally acquainted, and, as I have just had an opportunity of remedying this lapse, it may not be without interest if I give my impressions, especially in view of the noteworthy improvements and ameliorations that have of late been effected there.

In speaking of Vichy we have to deal with two distinct and equally remarkable establishments, first, the thermal establishment proper, where the curative properties of the waters are brought to bear by internal administration, by baths and other hydrotherapeutic measures, and by an elaborate system of calisthenics, comprising all the most modern appliances organised by an adept in the application of this method of treatment, Dr. Charles Vermeulen, professor of mechano-therapeutics. Then, too, there is the Compagnie Fernière de Vichy, by whom the waters are bottled and dispatched to the uttermost corners of the earth.

The company, having obtained a prolongation of their lease from the State, have expended vast sums in the construction of a palatial bathing establishment on a scale, and with a luxury of detail, certainly unsurpassed and probably unequaled. With the present installation it is possible to give 600 baths daily without undue pressure, and the douches may be numbered by thousands. Every possible appliance is provided, and the department of hydrotherapeutics is under the direct control of qualified practitioners specially experienced in this class or department of practice.

Visitors to Vichy may be divided into two categories—those sent by their medical advisers to undergo a set course of treatment for the cure of particular ailments and a second class, perhaps the more numerous, who seek in a "cure" the means of recuperating after the fatigues of active social or city life. For the latter, ample means of distraction are provided. Apart from the beautiful grounds and parks, there is a magnificent casino, which comprises a theatre capable of seating 5,000 persons, as well as a spacious restaurant and a Trink Hall.

Vichy Therapeutics.

The Vichy waters are specially famed for their curative action in chronic affections of the stomach, dyspepsia, gastric dilatation, hyperacidity and the like, as well as in the treatment of the prostatic class of nervous disturbances of digestive origin. They are likewise reputed for the action of certain chronic diseases of the hepatic apparatus, such as liver congestion, causthal jaundice, biliary lithiasis, the early stages of cirrhosis, &c. They exert a sedative and antiseptic action in intestinal catarrh, and in diabetes marked improvement may be obtained thereby. Nor is their action less marked in disturbances of the renal function, their ability to raise the blood pressure, therefore, it can conveniently be administered in cases where the heart-function is debilitated—e.g., in degenerativo musculi cordis.

The conscientious way in which the indications for treatment are fulfilled calls for special notice, and it is impossible not to admire the manner in which the various therapeutic methods are carried out, and the elaborate appliances provided for the purpose.

There are three principal springs belonging to the State: the Celestins, the Grande Grille, and the Hôpital. At the bœuttes the various waters are dispensed gratuitously by fair maidens, and in the early morning they are the resort of certain drinkers in the artistically-designed hall make up a charming picture. I must, however, say a word or two about these three springs, which differ greatly in composition and therapeutical properties. The water of the Celestins issues from the ground at a temperature of 15° C. (60° F.). It is sparkling and agreeable to the palate, and is specially recommended for the stage of chronic gravel, nephritic colic, diabetes and the early stages of chronic affections of the urinary tract. The Grande Grille bubbles up from the ground in a copious stream, giving off large volumes of carbonic acid, and it contains seven grammes of saline constituents per litre. In spite of this richness in salts it is agreeable to drink and does not hinder digestion. This is the water prescribed in chronic congestive affections of the liver and abdominal organs, diabetes and hepatic colic. The Hôpital spring issues at a temperature of 31° C. (88° F.), at the rate of 60,000 litres per hour, and is the water most in demand in the treatment of chronic affections of the digestive apparatus. It is, moreover, a very palatable alkaline table water.

A visit to the bottling department is an indispensable part of the programme on visiting Vichy, when one reflects on the fact that from this establishment some 16,000,000 bottles are sent out each year all over the world. Especially interesting was the organisation for ensuring the purity of the water prior to bottling, as well as the complicated and ingenious apparatus for thoroughly cleansing the bottles before being filled. I can safely say that no precaution is omitted with these objects in view. The ease with which the Celestins waters can be procured anywhere renders it possible to employ them habitually at
distance from Vichy. The water from this spring provides an admirable table water, well suited for the use of dyspeptic and "bilious" persons. Incidentally I was privileged to see the elaborate mechanism by which the saline contents of the waters are obtained and made up into pastilles. After being dried the salt is supercarbonated with gas drawn from the wells before being made into a paste to be stamped out. In the present two hours since my disposal it is impossible to do justice to the most delightful and well-organised health resort which I have ever visited. The thermal station is open all the year round.

The establishment charges are very moderate, and I was struck by the comparative cheapness of the hotel accommodation; in fact, it is possible to live very comfortably for from eight to ten francs a day inclusive, even in the first-class hotels.

**The Operating Theatres.**

**ROYAL FREE HOSPITAL.**

**Operation for Perforated Gastric Ulcer.—** Mr. T. F. Legg operated on a man, aged about 45, who had been bedridden with abdominal pain coming on about two hours after a meal. The patient had been subject to indigestion and recurrent attacks of pain for some years. On the day of admission he had been in his usual health till about two hours after having had his tea. The pain came on quite suddenly and very severely, causing him to vomit; he at once went to the hospital. On examination, the upper part of the abdomen was found to be very rigid and markedly tender over the right rectus muscle in the region of the pylorus. The liver dulness was present, there was no evidence of extravasation of the stomach contents, his pulse was 118, small and soft; his face was somewhat pinched. Mr. Legg saw him about an hour after admission. The abdominal rigidity was then not so marked and the pain was not quite so severe. The abdomen was at once opened by a four-inch incision just to the right of the middle line. No gas escaped on opening the peritoneal cavity, but a little thin blood-stained fluid was seen in the neighbourhood of the pylorus. On examining this region an area of induration as large as the palm of the hand was found on the posterior wall of the pylorus; in the centre of this indurated area a hole which would admit a No. 6 catheter was found, and from this opening the contents of the stomach were seen to be slowly exuding. This area was at once packed off from the rest of the peritoneal cavity by gauze, and to gain more room the left rectus was divided for about two inches by an incision at right angles from the centre of the first incision. The stomach was so adherent to the liver and omentum, and itself so contracted, that it was impossible to bring up the pyloric end to the wound. Owing to the indurated condition of the stomach walls around the perforation, it was impossible to close the hole either by Lembert's sutures or by a purse-string suture; the silk employed cut out at the contact of the sutures. The omentum, therefore, was placed over the hole and fixed to the stomach by several interrupted sutures. The abdominal cavity in the neighbourhood was wiped quite dry by gauze swabs, a drainage-tube was then placed in position over the site of the perforation, and around the tube straps of gauze were packed to prevent extravasation. Most of the first incision was left open and the gauze packing brought out on the surface; the incision in the left rectus was closed by interrupted sutures passed through all the layers of the abdomen. Mr. Legg said the first point of interest about this case was the short time which had elapsed since the perforation had taken place and the time the operation was performed: this was about three hours, and it was the most important point in the prognosis; the shorter the interval which elapses the greater the prospect of a successful result of the operation. The next point worthy of note, he considered, was the time the perforation took place in relation to the fullness or emptiness of the stomach; in this case about two hours since the last meal, the stomach would be moderately full and considerable extravasation of stomach contents would probably result; however, owing to the small size of the perforation very little stomach contents had escaped, and at the operation the stomach was found not to contain much food; this was shown first by its not being distended, and secondly by only a thin, yellowish, watery liquid with a small quantity of food escaping from the perforation during the necessary manipulations. The greater the quantity of stomach contents which escape, he pointed out, the greater the difficulty in effectually cleansing the peritoneal cavity, and if this is incomplete the chances of the patient recovering are very small. It is essential, he said, to prevent the peritoneum becoming附集 a lubricating layer of food by the eversion of the greater part of the operation and this is most efficiently effected by gauze packing. He next remarked on the method of cleansing the peritoneal cavity; this, he said, depends very largely on the extent of the extravasation. When it is localised to the area of the perforation, it is best to use gauze swabs or sponges only, and not to irrigate it with antiseptic solutions. On examination of the peritoneal cavity. The method employed to close the perforation is, he thought, of interest, and was the only one capable of adoption. Owing to the extent of the induration in the stomach wall and the adhesions to the liver and transverse colon, it was quite impossible to think of attempting excision of the ulcer. It is known, he said, how readily the omentum forms adhesions to other abdominal viscera; for example, to the appendix, where it often forms part of the wall of an abscess cavity and serves to prevent extravasation of the pus, and again during operations on inflamed Fallopian tubes and ovaries the omentum is often found to be adherent to them, therefore the omentum was used in this case to close the perforation. (That it did this effectually he was not sure, but no further perforation of the stomach contents took place. A chemical examination of the fluid exuded during the first two or three days after the operation was made and no gastric juice was found.) Other points of interest, he remarked, were the age of the patient, the situation of the ulcer, and its evident chronicity; the hardness suggested that the process was a chronic inflammatory one and not malignant. Mr. Legg said it was interesting to notice, too, that this patient had previously been treated for gall-stone colic and the diagnosis of the two conditions is not always easy—in fact, it is always well to bear in mind that the two conditions may occur in patients at about the same age, and in both there may be a history of recurrent attacks of pain in the region of the epigastric region. At the same time, if the patient the initial severity of the symptoms had diminished considerably and it was important, he thought, to remember that in cases of perforated gastric ulcer this sometimes occurs, and a knowledge of this fact will serve to prevent the surgeon missing the most favourable period for operation, and also to guard against making a mistaken diagnosis. In connection with this, the pulse, he pointed out, is a most important factor; in this patient, although the local symptoms had improved there was no alteration in the character of the pulse, which was rapid and small.

The after-progress of the case was satisfactory in
every way; the gauze drains were removed on the eighth day and the drainage-tube a few days later; the wound had wonderfully healed at the end of a month.

For the first week after the operation the patient was fed entirely per rectum to give the stomach a complete rest, in the hope that the ulcer would heal; then feeding by mouth was commenced, and increasing quantities gradually given, until, at the end of about three weeks, he was taking ordinary diet without pain or discomfort. He left the hospital well six weeks after the operation.

The annual migration into the hop-districts of a considerable number of the poorer section of the community is recognised as quite one of the institutions of London. For this band of workers such an excursion is looked upon as the one holiday of the year, eagerly anticipated, for, although there is plenty of hard work to be done and little or no time for actual amusement, yet they can at least enjoy the benefits of fresh air and change of scene. Anyone who has witnessed the departure from one of the South Eastern Railway termini of a "pickers' train," and has seen the excited groups of East-enders huddling into the carriages, their worldly goods stowed away in an old sack or a saucepan being lugged in with them, will realise what this outing means to them, and with what earnestness it is undertaken. Towards the end of August and the beginning of September many thousands of pickers, young and old, for each member of the family that is able to do so takes a share in the work, will be leaving the City for the hop-fields. If the weather should be propitious, the life is not altogether unpleasant, and they reap the rewards of their labour, but when the season is wet and the yield scanty, real hardships then begin. The unaccustomed exposure to the damp air during the night, the proximity to the soil, the neglect or insufficiency of sanitary arrangements, all contribute to render illness peculiarly prevalent among them. The diseases which are most commonly incident are pneumonia, especially in infants, in whom it assumes a broncho-pneumonic type, diarrhoea, and acute rheumatism. Should one of the pickers happen to develop enteric fever, the extreme danger which may thus accrue to the surrounding encampment is obvious, while the possibility of infecting a whole district or town from contamination of its water supply is one which must ever be borne in mind. The ignorance of hoppers in hygienic matters is profound, and anything like compulsion would be strongly resented by them. The most satisfactory method of imparting sanitary instruction would probably be that of camp visitation by health-visitors, medical or otherwise, who would have no difficulty in working in conjunction, at any rate to start with, with some of the many excellent missions which have been established for the spiritual and physical benefit of hop-pickers.

It is encouraging to note that some of the larger factors provide temporary accommodation in the shape of shelters for those employed in their gardens, such structures being more especially designed for the use of the women and children. We doubt not that in the future it will be found quite practicable to furnish some of these as hospitals. Many of the neighbouring cottages have, indeed, served as such in times of pressure, but for the most part they are anything but fitted for the reception of sick persons. We are reminded of a celebrated picture in which a medical man in immaculate professional attire is depicted kneeling on the ground in an encampment while examining the chest of a sick child. The thought of what will be done with the little patient, and where she will be taken after the diagnosis, perhaps of pneumonia, has been pronounced cannot help striking the observer. Similarly, the question arises in the actual life of the hop-picker and his family. All praise is due to those who are endeavouring, by unselfish devotion, to make the lot of the hopper more endurable, and it is to be hoped that the way will be opened for a better medical and hygienic organisation of the hop districts than has hitherto prevailed.

SENSORY MANIFESTATIONS IN APPENDICITIS.

Disturbances of sensation as symptoms in association with diseases of the abdominal viscera, and particularly of the intestines, are notoriously fallacious and, if relied upon, misleading. Severe pain may accompany comparatively insignificant lesions, while, on the other hand, mere discomfort may be all that is complained of in presence of the gravest mischief. Tenderness in association with pain is no doubt of greater import, but the individual appreciation of what constitutes tenderness varies within such wide limits that only the experienced observer can safely gauge its degree and significance. As Mr. Mansell Moulin points out in a recent clinical lecture, the abdominal viscera
are, for the most part, insensitive to pain, their nerves not being directly connected with the sensorium. The occurrence of pain depends upon circumstances, mostly of mechanical order, which have no necessary and invariable relationship with the particular lesion. It has been remarked that while the intestine itself is singularly insensitive to manipulation, the parietal peritoneum reacts very promptly, as, for instance, when traction is applied to the mesentery. Inflammation, so long as it affects only the intestinal structures, including the visceral peritoneum, is unfelt, but the moment it involves the parietal layer pain becomes a prominent symptom. These considerations may explain how it is that in certain cases of acute inflammation of the vermiform appendix little pain or tenderness may be complained of, and the pain, when present, is probably due to the peristaltic action of the cæcum or of the appendix dragging upon the attachment of the peritoneum to the abdominal wall. Pain is especially likely to occur when the appendix is adherent or the mesentery is short or has become twisted on itself. It follows that the cessation of the pain may be due to temporary paralysis of the muscular layer of the cæcum and not, as one is apt to conclude, to subsidence of the inflammation. Absence of local pain, as Mr. Mansell Moulin points out, does not indicate anything. Tenderness, again, may not be felt so long as the inflammation is limited to the bowel, and its presence indicates that the process has extended to the parietal peritoneum or to the cellular tissue beneath it. The occurrence of pain at the much decried McBurney's point may be taken to indicate that the inflammatory process has extended to that part of the parietal peritoneum which is in closest and most immediate connection with the lymphatics that run from the inflamed organ. Inasmuch, however, as the lymphatics from other viscera may either communicate with those from the appendix or lie in their immediate neighbourhood, tenderness in this locality is not of itself positive evidence of appendicular mischief. In addition to the deep tenderness, inflammation of the appendix is often associated with a marked degree of cutaneous hyperæsthesia—a phenomenon which does not admit of ready explanation. The sudden disappearance of this superficial tenderness has, in some instances, coincided with gangrene of the appendix, and this point is one worth bearing in mind in discussing the advisability of immediate operation. It follows that in cases of suspected appendicitis, pain and tenderness, when present, are symptoms of very variable significance, and their absence, in whole or in part, conveys no assurance of freedom from serious mischief. Even less trustworthy is the precise localisation of the pain, for, as we have shown, this is dependent on circumstances and conditions only indirectly connected with the actual lesion.

THE CENTRAL MIDWIVES' BOARD AND IRISH MATERNITY HOSPITALS.

The long-expected schedule of rules framed under Section 3 of the Midwives Act, for the regulation of the proceedings of the Central Midwives' Board, the training and registration of midwives, and the practice of midwives, has at last been issued by the Privy Council. It is an important document, which calls for full consideration by the medical profession at large, and by the authorities of the different hospitals for the training of midwives. Taken as a whole, it may, we think, be truly said that, while the principles which appear to have governed its drawing-up are good, the details by which these are to be carried out are in places inexplicable and in places wrong. The general principles appear to be five in number:—That every midwife must be properly trained; that she must pass an examination held by the Central Midwives' Board; that she must be cleanly in her person and attentive to her patients; that she must not undertake the management of cases of abnormal labour; and that she must keep careful records of all cases which she attends. These principles are, as we have said, good, but this cannot be said regarding many of the details. Will it be believed that the very first clause relating to the course of training of midwives, a clause which, presumably, is drawn up in order to ensure the proper training of midwives, has the effect of rendering any nurse who has been trained at the great Irish maternity hospitals ineligible? This may or may not be intentional; the fact remains that a woman who spends three months in acquiring a knowledge of midwifery "under supervision satisfactory to the Central Midwives' Board" will apparently be eligible for admission to the roll, while a woman who has spent six months in the greatest midwifery hospital, perhaps, in the world is ineligible. Women trained in Irish maternity hospitals have always held the highest reputation, and been most sought after for nursing appointments, and now the Central Midwives' Board considers that they are not suitable even to be examined for admission to the midwives' roll. If we recollect rightly, the promoters of the Bill, and notably Mr. Heywood Johnstone, gave, during the Committee stage of the Bill, the assurance to those interested in the Irish hospitals that nothing would be done that would interfere with the rights of Irish-trained midwives; and this is how that assurance is carried out! The provisions in the clause which shuts out nurses trained in the great Irish hospitals are two in number. In the first place, it is made obligatory that the nurse must attend and personally deliver twenty cases of labour. In the second place, she must nurse twenty cases for ten days after confinement. We do not cavil at these requirements as applied to small institutions, from many hundreds of whom the Central Midwives' Board will, doubtless, receive and accept certificates. In cases where instruction is of necessity elementary, and perhaps fragmentary, increased practice must be added to supplement it. But, in large maternitys, where there are proper courses of instruction, where the number of cases which can be watched, may be counted by hundreds and not by
Notes on Current Topics.

Chronic Cyanosis.

The most common conditions in which a more or less persistent cyanosis is met with in practice, especially if it be limited to the face and extremities, are organic heart disease and those affections of the lungs accompanied by insufficient aeration of the blood. Of the former, congenital morbus cordis, and of the latter, chronic emphysema, are the most familiar examples. Cyanosis is also seen in poisoning from certain coal-tar derivatives, such as phenazone. As a symptom it is always alarming, indicating as it does a diminished oxygenation of the blood, and consequently, of all the tissues in the body. Dr. Osler, writing in the *American Journal of the Medical Sciences*, has described another variety, namely, that associated with polycythemia and splenomegaly. Nine cases are quoted in which the cyanosis was most marked in the face and hands, but it affected the whole body in three instances. A high degree of polycythemia was seen, the maximum blood-count being 12,000,000 per cm. In seven cases the spleen was enlarged, but this may probably have been due to the passive congestion in which all the organs hared to a greater or less extent. Pigmentation of the skin was observed in five of the cases. The commoner symptoms complained of comprised weakness, headache and vertigo, while attacks of nausea, vomiting and constipation were seen in others. There was no fever. The pulse-tension was generally increased. A comparison is drawn between some of these symptoms and those experienced by mountaineers and aeronauts, in which it is obvious that all these conditions present some points of similarity. The new symptom-triad is one of great interest, but further investigation must alone decide if it be one which is characteristic of a separate clinical entity.

The Value of Subconjunctival Injections.

The arrangement of the vascular and lymphatic circulations of the eyeball is so ordered that it would seem possible to influence them by local measures to a greater degree than if such attempts were made through the medium of the general circulation. In a paper read before the American Ophthalmological Society at Washington by Dr. Bull, of New York, the present position of subconjunctival therapeutics is set forth. The various fluids and solutions which have been injected under the conjunctiva in morbid conditions of the eye have generally been antiseptic in nature, such as a 1 per cent. solution of mercuric cyanide or corrosive sublimate, or have consisted of "normal saline," which can be either used alone, or employed in conjunction with sterilised gelatine, as has been recommended in detachment of the retina. The mechanism by which these injections act is stated to be the change in composition of the aqueous humour that is induced by the irritating action of the substances injected upon the blood-vessels. An increase in the serum albumin of the aqueous humour results, and it is found that its hemolytic power is greater shortly after an injection. Sodium cinnamate or hetol has also been employed in a 1 per cent. sterilised aqueous solution with some success in the treatment of corneal ulcers, corneal herpes and interstitial keratitis. Dr. Bull believes that a 1 per cent. solution of corrosive sublimate is capable of exerting at times a favourable influence upon reparative corneal affections, but he does not consider that subconjunctival injections are always superior to other modes of treatment.

Artificial Sugar and Infantile Mortality.

The need of carbohydrates which exists in the human organism at an early period of life has been fully provided for by Nature, and yet fewer practices are more commonly seen, especially among the poor, than that of supplementing the natural supply by the entirely haphazard administration to infants of almost any sweet thing that can be obtained. Whether the sugar be given as such, or else in the form of starchy foods, is immaterial, the result being only too often that a troublesome form of fermentative gastrointestinal disorder is set up. When the infant cries with pain more sweets are given, the effect of which is to aggravate the morbid process. If the sugar thus administered should happen itself to be adulterated worse things happen. It is disquieting, therefore, to learn that there is a considerable quantity of chemically manufac-
tured and metallically dressed sugar upon the market, some of which is contaminated with chloride of tin, and that this is consumed by large numbers of infants. This artificially prepared sugar, which is imported from abroad, is freely used in many quarters in feeding-bottles, with results which are disastrous to contemplate. The causes of the increase in infantile mortality are sufficiently numerous without the addition of any toxic destructive element to such a common household commodity or the use of a dangerous substitution-product. It is to be hoped that the sale and importation of this substance will be prevented in future.

The Irritability of the Facial Muscles.

The extreme mobility of the muscles of the face and their ready response to different psychical states are features which distinguish them from all other muscles of the body. To such an extent are they indicators of the prevailing emotion and mental habit of their possessor that by their contraction or relaxation we are enabled in some degree to estimate the character of an individual by the expression of his countenance. From the point of view also of the neurologist the facial muscles are interesting, since from the independence of their motor and sensory nerve supply, and the fact that these may both be inhibited together, the study of their muscular re-action can be prosecuted as well as in an animal experiment. The observations of Dr. Charles L. Dana, of New York (6), upon the effects of tapping the various motor and sensory nerves, and the tendons themselves, with a view of eliciting reflex contraction thereof, are of interest because they may be of assistance in the diagnosis of certain nervous diseases. Thus, it is found that the two chief normal reflexes of the facial muscles are the supra-orbital and the fronto-orbital, which are contractions of the lower lid brought about by striking the point of emergence of the supra-orbital nerve and the frontal aponeurosis, respectively. Other reflexes also exist, such as the auri-orbital, the external orbital, the frontal, and the naso-oral; but these, together with the naso-mental, the supra-orbito-nasal, and the frontal skin reflex, are more often seen in abnormal conditions, as in certain forms of paralysis. Some care is required in the method of producing the reflexes, a small rubber-tipped hammer being the best percussor. The patient’s attention must be diverted from the procedure by causing him to fix his gaze upon some distant object. It is not easy to elicit the responses in obese or emaciated persons and they are invariably more active in children. Chvostek’s symptom, or general facial response to a stimulus, has been observed in tetany, but Dr. Dana has also seen it in states of great psychical or toxic irritability. The abnormal reflexes are said to be more common in the psychoses, especially in paroxysm and in active melancholia.

Special Hospital Management.

The way in which some members of the staff of special hospitals have used, or rather, grossly abused their position has often been the matter of very severe and adverse criticism. Take the case of a gentleman who was under the care of a medical man for some time, where a consultation was suggested with a surgeon connected with a certain hospital. To save expense, however, he was taken to the hospital for free advice. There the surgeon advised an exploratory incision—the case a perfectly clear one—the patient having the choice of the hospital or a nursing home mentioned by the surgeon. Now, it is perfectly well known that the surgeon has a very large interest in this home, and to it the patient was removed. The operation was performed, without the knowledge of the practitioner who had immediately before been in attendance, and, unfortunately, his patient died in the home within three weeks of the operation. The regular medical man had his opinion previously confirmed by the consultants. Here is the case of a surgeon operating upon a patient who attends at a free hospital at what may almost be called his nursing home, and is sometimes named his. He most undoubtedly committed a gross breach of professional etiquette in failing to recognise the medical man who had charge of the case. Such a case as this, and others which could be cited, indicate that the suspicion with regard to the grave abuse of special hospital appointments—only a few, we hope—are not unfounded. The matter is one which seems to us to call for inquiry.

The Use of Eserine in Keratitis.

Phlyctenular keratitis, a not uncommon disease during childhood, is one of the forms of corneal disease that the general medical practitioner not infrequently retains under his own care. The tendency of the great majority of cases is to get well, though this does not always happen, and as the disease progresses the risk of permanently injuring the eye by the forcible retraction of the lids increases. In this stage, and, indeed, earlier in the disease, the most general local application is a solution of tropia, in varying strengths. Its great recommendation is that it acts as an anodyne, though its anodyne effects are evanescent. It seems almost a heresy to breathe anything against so popular a remedy; but we think that the marked mydriatic effects of the alkaloid, by allowing a great increase of light into the inflamed organ, more than counterbalance its anodyne properties. In eserine the profession has an alkaloid of known worth, that by its power of contracting the pupil excludes light from the inflamed organ and produces gradually a marked diminution of pain and a decided lessening of the inflammation. We refer to this because we do not find eserine mentioned in connection with keratitis in students’ hand-books.
Dust-Arresting Respirators.

The many evil effects attendant upon the inhalation of dust and metallic particles, by employees engaged in certain trades, is well known to those members of the medical profession who practise in manufacturing centres. In the past, various attempts have been made to provide a suitable respirator which will prevent the passage of such particles, but none of the devices have been marked successes. The Society of Arts is now in process of making another effort to stimulate inventors to turn their attention to this great want, and under the terms of the Benjamin Shaw trust, it will award in January, 1904, a prize of twenty pounds or a gold medal for the best dust-arresting respirator for use in dusty processes and dangerous trades. This is not the first time that the Society has made a similar attempt. So long ago as 1822, it awarded to a Mr. Abraham, of Sheffield, a gold medal for a magnetic guard to protect persons employed in dry grinding. The guard was fitted with a number of magnets, which attracted to them the fine metallic particles thrown off in the process of grinding. It is interesting to learn, and enables one to understand a little better, that curious compound, the British workman, that the main objection to the use of this protector was raised by the workmen themselves, who feared that the lessened risk attached to their employment would lower their wages. In the present instance, the Society requires an apparatus that is light, simple, and inexpensive; that will allow no air to enter the mouth except through the filtering medium; that will not permit expired air to be rebreathed; that will be effective in arresting dust particles; and that will not offer an appreciable resistance to respiration. Inventors must send in specimens of their invention not later than December 31st, 1903.

"Christian Scientists" or Criminal Lunatics?

A very sensible suggestion is made by an American medical man, writing in the Journal of the American Medical Association, with regard to the action that should be taken by the profession to check the present riot run by so-called "Christian Science" through America. He had been rendered righteously indignant by the sight of an elderly patient with a right irreducible femoral hernia, complete constipation, facial vomit, and all the other signs of a strangulation demonstrated and prayed over by, as he says, people calling themselves Christians, Scientists and Healers, until she died, medical aid being refused. His suggestion is that the profession, at large in America should report in full every such case that comes to their knowledge, and that at the next meeting of the American Medical Association proper and decisive steps should be taken to obtain State, and, if possible, national legislation, which will insure the punishment of those directly responsible. It is quite time that some such steps were taken. It is a curious reflection that coincidently with the general appreciation of the necessity for an increase in the American population, an organisation should spring up whose direct tendency is to diminish the population. The common sense of the average American is considerable, but the hysterical tendencies of a minority are also very great, and sometimes are sufficient to lead an outsider to suppose that the common sense majority had been swamped. It is time that the latter asserted itself. Faddists and monomanics may be tolerated up to a certain point, but once they exhibit murderous tendencies they should be controlled in a manner identical to that by which other criminal lunatics are rendered harmless.

Rheumatism and Pseudo-Rheumatism.

There are few terms in the whole range of medicine used in a looser way than the word "rheumatism." Wherever there is pain for which no simple explanation is forthcoming, it is at once dubbed "rheumatic." It is not merely that the meaning of the word is hardly sufficiently defined and its legitimate use thereby restricted, but it is applied improperly and unnecessarily to the most varying conditions, which have nothing in common pathologically or clinically beyond the presence of the symptom of pain. In a recent paper, Dr. James Walsh, of New York, has entered a protest against this careless, and has enumerated several cases where a rough and ready diagnosis of rheumatism was made, with, as might be expected, very evil results in treatment. Every physician of observation could add many more examples from his own experience. In neurotic conditions, the patient is commonly treated with the usual depressant "anti-rheumatics," which are everything but serviceable. Similarly, many true organic nervous diseases, such as tabes, are at first regarded as rheumatics. On the other hand, deformities such as flat-foot and other causes disturbing the harmony of muscular work, and thereby giving rise to muscular pain are overlooked by virtue of the same "blessed word." A case similar to this is where a diagnosis of pleurisy is made in commencing phthisis, the fact being that the extra strain put upon the base of the lung is causing genuine fatigue pains in the diaphragm and lower intercostal muscles of the affected side.

Intestinal Absorption.

A very interesting series of experiments has been made by Signors Baldacci and Guidi, of Pisa, on the effect of cocaine on the power of absorption of the small intestine. They isolated a loop of gut, tied it at the extremities with ligatures, and in the middle, so as to make two chambers of equal dimensions, and injected a solution of cocaine into one chamber and an indifferent fluid into the other. After a certain interval of time they introduced into each of these intestinal chambers the same amount and quality of an absorbable material, the presence of which could be recognised, and the quality of
which could be estimated with comparative ease. Although the rate of absorption in the oxygenised and unoxygenated segment was slight, it was found to be constantly slower in the medicated one, and it was found that the inhibition held good for soluble substances and fatty bodies. They conclude that the absorption power of the intestine is not due to purely physical conditions, but to a specific activity on the part of the intestinal epithelium.

Fetal and Infantile Typhoid.

The occurrence of enteric fever during intrauterine existence has, previous to the discovery of the typhoid bacillus, been considered to be a rare event. In a paper read before the New York Academy of Medicine (a) Dr. Morse has collected a sufficient number of cases in which the condition has been proved by autopsy and cultures. The question of the transmissibility of the bacillus from the maternal organism to the fetus via the placenta is, therefore, finally settled from the clinical standpoint, although it had been demonstrated experimentally by Chantelesse, Widal, and others. The high degree of mortality in fetal and congenital typhoid is held to be due to the septicaemic nature of the infection, and, for the same reason, the characteristic lesions of intra-uterine enteric fever are generally conspicuous by their absence. In infants under two years of age, the disease does not seem to be a mild one, but although it might be imagined that owing to their greater susceptibility to bacterial infection in general they would be more liable to contract typhoid, yet the experience of epidemics and the information furnished by statistics go to show that it is of a comparatively infrequent occurrence. The symptoms at this period of life are somewhat different to those presented in the adult, thus, the nervous manifestations are apt to be more severe, the rash more abundant, and the temperature higher and more irregular. In 32 of such cases collected by Dr. Morse, 16 died, giving a mortality of over 50 per cent., which figure is higher than the average, owing to the severe type of case selected. It is possible that if the Widal reaction were more systematically tried in cases of infantile gastro-intestinal disorders milder types of the disease might be detected, but where this has been done the results have been negative.

The Dangers of Paraffin Injections.

We have on more than one occasion called attention to the fact that the injection of paraffin for cosmetic purposes is by no means devoid of risk, and is, therefore, not to be lightly undertaken. The warning is the more necessary since, while we are favoured with ample details of the more remarkable successful cases, comparatively little finds its way into print in respect of the drawbacks and dangers of the procedure. Only the other day a New York surgeon reported (b) an instance in which the injection of paraffin beneath the skin of the nose was followed by instant embolism of the central artery of the retina with total and permanent loss of vision. The accident was probably due to the passage of paraffin into a punctured vein. Pulmonary embolism has occurred on several occasions with fatal results, and even the least of such dangers, that of necrosis of the superficial skin, is by no means a trivial accident; in fact, the damage can then only be made good by delicate and tedious plastic operations.

Are Isolation Hospitals Centres of Infection?

Two great arguments have been advanced against the system of hospitals for the reception of patients suffering from infectious diseases: first, that the aggregation of persons suffering from the same complaint under the same roof tends to increase the virulence of the infection, and thus to raise the mortality; and, in the second place, that such hospitals constitute centres of infection from which it spreads to the neighbourhood. The former objection does not repose on absolutely trustworthy data, and even if it were the case, and it has not been uniformly observed, that the hospital mortality was higher than among cases treated at home, the difference is by no means great, and is susceptible of many other explanations than that of increased virulence, as the result of segregation. The prevalence of small-pox in the vicinity of aggregations of patients suffering from this disease has been clearly demonstrated during the last few years, and the principle has been recognised and acted upon of isolating these hospitals as far as possible. Similar researches have been undertaken in Paris by Dr. Farnarier, and his results tend to confirm the view that these hospitals are really centres of infection, at any rate, as regards certain infectious diseases, notably diphtheria and scarlet fever. Less pronounced, so far as measles is concerned, this tendency to radiation is apparently non-existent in whooping-cough. As it is not always possible or even desirable to transfer these institutions to the outskirts of the city, the simplest way to minimise the danger of regional infection is to adopt the plan of building numerous small pavilions surrounded by trees, so as to create a protective zone of air between them and the nearest habitations.

Hysterical Fever.

The existence of a pyrexial condition in association with hysteria apart from any recognisable cause for the hyperthermia has been called in question, but there are a number of carefully made observations on record which seem to establish the fact of its occasional occurrence. In the course of his remarks on a case of the kind, Dr. Ughetti claims that the diagnosis may be made by noting the want of harmony between the temperature and the pulse rate and respiration. Moreover, in lieu of an increased excretion of urea, this "functional" fever is marked by a

---

(b) New York Medical Record. July 11th, 1903.
slowing down of metabolism as manifested by a fall in the proportion of urea excreted.

The Serum Treatment of Alcoholism.

The suggestion that it may be possible to combat ethylmania by the injection of serum, for all the world as if it were a microbial disease, is one which cannot fail to awaken feelings of scepticism. Nevertheless, the theory has been promulgated in all seriousness by Drs. Sapelier and Dromard avec preuves a l'appui, and its publication created a certain sensation. The object aimed at is to deprive the cells of the craving for alcoholic stimulation with which they are imbued, or which has been induced by pernicious habits. Their serum is prepared from horses that have been methodically alcoholised and the blood of these animals is asserted to yield a substance which, injected into the human being, restores to the cells their normal equilibrium. But if this substance be formed in the blood of the horse it ought logically to be present in that of the human alcoholic in whom, however, judging from clinical observation, it is conspicuous by its absence. We do not despair of the discovery of a means of overcoming the craving for alcohol; indeed, sundry agents are already much vaunted for this purpose, though the results are neither as marked nor as durable as the circumstances require. As it seems to be a rule in experimental therapeutics to endeavour to widen the sphere of application of remedies which have proved of service in particular maladies, we are surprised that no one has yet written in favour of the use of anti-diphtheritic serum and thyroid extract. They would no doubt prove as efficacious as the serum of the alcoholic horse.

Crime in Ireland.

The annual report of the General Prisons Board of Ireland, which was placed on the table of the House of Commons immediately before the prorogation, contains a very satisfactory account of the decrease of crime in the country. During 1902 the sentence of penal servitude was only imposed in 57 cases, the smallest number ever so sentenced; of the convicted, the greater number were sentenced for the minimum term of three years. There has been a steady decrease in the number of criminals since 1855, in which year 578 criminals were convicted, and there were 3,427 convicts in custody; last year the total number of convicts was 270. Even allowing for the great decrease in population, from 6,500,000 in 1855, to 4,500,000, it shows a very marked falling-off in the percentage of crime. Turning from this report to that of the Inspectors of Lunacy, we find that in 1851 the total number of lunatics in the country was 9,920 in a population of 6,500,000, and in 1901 the number of lunatics has risen to 25,000. The net increase of lunatics was nearly quadrupled, the ratio having risen from one in 657 to one in 178 of the population. Such a condition of things upsets the Lombroso theory of the co-relation of crime and lunacy. In Ireland we find that just as the people became prosperous crime against person and property diminished, which is in accord with common experience; but how can the alarming increase of lunacy during the past fifty years be accounted for?

The Death of the Marquis of Salisbury.

The death of Lord Salisbury, at the age of 73, marks the termination of a long period of ill-health of which very little information ever reached the public. Some ten years ago he began to be troubled by a tendency to obesity, which became more and more marked; indeed, at one time it inspired some anxiety, especially as it was associated with obstinate intestinal paresis, culminating on several occasions in attacks of quasi-obstruction only relieved with difficulty. This condition, no doubt, was in great measure brought about by the arduous nature of his pursuits, political and scientific, for Lord Salisbury, as is well known, sought relaxation from the anxieties of Government in laboratory pursuits. He, consequently, led a very sedentary life, and in spite of abdominal massage and a severe regimen degeneration of the kidneys ultimately supervened, one of the several forms of Bright's disease, with concomitant circulatory disturbance. Long before Lord Salisbury definitely relinquished the reins of office it was often manifest that the burden was at times almost greater than he could bear, and his continuance at the head of the Government was prolonged only in deference to the sense of duty, which induced him to see the country through a grave crisis before taking the rest to which he aspired, and which ultimately became indispensable. The fatal dénouement was determined by gradually increasing heart failure merging into coma. The country is now the poorer by a powerful intellect and by a commanding personality, respected at home and feared abroad.

Ambulatory Psychology.

The consciousness of individuality is subject to lapses during which the subject lives a purely automatic existence, wandering about, it may be, in an aimless manner until consciousness returns or until the victim is identified and brought under treatment. This mental condition virtually amounts to a suspension of the psychical constitution, and is by no means rare. Under the empire of this abnormal mental state, persons have been known to travel long distances, without money, to awaken in a place previously unknown to them, and which they had no conscious object in visiting. A correspondent relates the case of a telegraph operator who, one Saturday afternoon, while returning to his home in Pimlico, suddenly became oblivious of his surroundings and only recovered consciousness some days later at the Wolverhampton Police Station, whither he had been taken as a homeless vagabond. His memory was a blank as to the interval, but judging from his appearance he must have walked the whole of the distance on meagre fare. It was elicited that this was not the first occasion on which he-
had "lost himself," though never for so long a time. The pathology of this curious mental condition is obscure, but it usually occurs in subjects of a neurotic stock, and there is, in some instances, a history of epilepsy. The most serious aspect of this morbid state is that the subjects may, while intellectually unconscious, perform unusual and even criminal acts of which they have no recollection when they recover. By a curious coincidence several instances of the kind have of late attracted attention, and this may open the eyes of the public to the importance of certain precautions in dealing with persons thus afflicted.

**Nasal Dysmenorrhoea.**

The presence of erectile tissue in the nasal fossae, and the close connection between this structure and the genital function, lends some plausibility to the suggestion that dysmenorrhoea is sometimes directly due to intra-nasal lesions. A priori, the fact would not strike one as more remarkable than the intimate connection that has been shown to exist between nasal obstruction and asthma, for instance. What may be termed the genital area in the nose has been located by Dr. Fliss in the tubercle of the septum and the inferior turbinal, and the principal argument advanced in favour of the existence of a nasal form of dysmenorrhoea is based on the results of intra-nasal medication. Dr. Linder, of Munich, claims that in certain recorded cases anaesthesia of the nares by solutions of cocaine or menthol invariably determined the disappearance of the uterine pain. Going a step further, it is stated that irritation of the nasal mucosa during laparotomy caused modifications of the uterine circulation and contraction of its muscular structures. If this be really the case a pinch of snuff ought to prove a trustworthy ecletic, but we are far from convinced of the existence of the alleged functional relationship.

**Overcrowding in the Profession.**

More than one writer recently has taken the trouble to show by statistics (what most of us know well enough by experience) that the prospect of prosperity in the medical profession in these countries is yearly diminishing. In the last twenty years it is said that the average income of a medical man in England has fallen from a probable four hundred a year to something under three. At the same time, the mortality in the medical profession is higher than in most others, and in particular the death-rate from suicide, already enormous, is every year increasing. This is certainly a dismal enough prospect, but, if we may judge from recent articles in *Le Temps*, things are not any better in France. "We want," says that paper, "merchants, manufacturers, farmers and colonists, but not doctors. France has more doctors than she wants." The following cutting from our French contemporary repeats the case—pitiful enough, though not lacking in the ludicrous:——"A physician was accused of stealing some statuettes, an umbrella and some cosmetics at a large department store. He confessed that he took the goods to pawn them to get food to eat. He stated that he had only a single patient and that the latter was ill only at long intervals."

**The Mouth in Diagnosis.**

Many interesting and instructive pages have been written on the state of the tongue as a guide to the diagnosis of visceral disease, but it may be questioned whether adequate attention is paid by the average practitioner to the state of the teeth and gums. It is a matter of common knowledge that the continued absorption of toxic products in pyorrhoea alveolaris may, in the long run, determine grave forms of anaemia, simulating the pensive, and Dr. Walter Carr records a case (Lancet, August 22nd, 1903, p. 525) in which the symptoms presented a close resemblance to typhoid fever. It cannot be doubted that numerous instances of irregular temperature and cachexia, not to be explained by any ascertainable physical signs, are due to this process of chronic intoxication by products generated in the buccal cavity. Even in such a common condition as that of dyspepsia medicinal treatment is but too often resorted to, with ephemeral relief, when the root of the mischief is to be found in dental imperfections. The hygiene of the mouth is a point which might well be included in the education of school children, since its influence on the general health is fully as important as any.

Dr. G. Sims Woodhead, Professor of Pathology at Cambridge University, has been elected President of the Congregational Total Abstinence Association for 1904.

**Special Correspondence.**

[We do not hold ourselves responsible for the opinions of our correspondents.]

**BELFAST.**

**The Question of Consumption.** — The proposed public provision of sheds for the open-air treatment of consumption in the Ormeau Park is provoking a good deal of criticism. The system of public shelters as used in Berlin, and described in this column some weeks ago, sounds very attractive, but its adoption in such a park as the Ormeau Park in Belfast, daily crowded with children playing, and surrounded by streets of working-men's houses, is open to grave objections. As it is merely a proposal on the part of some members of the Corporation as yet, it is doubtful if it will go much further, seeing the opposition it is encountering.

**The Poor-Law Medical Officers.** — The Poor-law medical officers, in their endeavour to obtain better conditions of service, are not finding it all plain sailing in Ulster. An eminent member of the Irish bar, himself an Ulsterman, once stated that no such hard swearing is ever heard at the Law Courts in Ireland as is heard when Ulster farmers are giving evidence in cases involving questions of money. It is hardly to be expected, therefore, that Boards of Guardians consisting largely of these same farmers will quietly allow all the claims of the medical men, and loud and vigorous are their protests in the Press and elsewhere. They make much of the fact that these same medical men made strenuous efforts to obtain their present posts, and try evidently think it rank ingratitude that, having obtained them with their scant emoluments, they should venture to "ask for more." It is a well-known fact," writes
 Correspondence.

CORSETS AND CANCER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sir,—In your recent article on "Corsets and Cancer" you seem to me not to lay sufficient stress on the connection which exists between the increasing prevalence of cancer, especially of the womb, and the universal custom of corset-wearing among women. I have noted that that type of corset which is most prevalent is one which allows the female organs to be in a state of chronic irritation, and which, if prolonged, may lead to cancer.

I am, sir, yours truly,

J. C. McWALTER.

Dublin, August 17th, 1903.

QUACKS AND QUACKERY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sir,—It seems to me that your excellent leading article of to-day, August 19th, and the other editorials and correspondence which during late months have appeared in your pages, all serve to emphasise or support the suggestion I made in THE MEDICAL PRESS AND CIRCULAR of July 15th. I suggested that the energies of the profession in respect to legislative reform should be directed towards education of the legislature as to the real facts of the situation. I suggested that the Government might be urged to appoint a Parliamentary Committee to inquire into the theological knowledge of quack medical practice, including the manufacturing and sale of quack medicines. Such an inquiry would establish the fact that whatever benefits might accrue to the profession from more complete protection, these benefits would be outweighed a thousandfold by the advantages which would be conferred upon the mass of the people. Parliament will never pass a law with the sole object of benefiting the profession; and it is not necessary such a law should be passed at all. A Parliamentary Committee on medical practice and insurance would be a powerful enough body to combat the worst abuses.

I am, sir, yours truly,

A Consulting Dental Surgeon.

August 19th, 1903.

LITERATURE.

PROTOZOA AND DISEASE. (a)

Mr. J. JACOB CLARKE's excellent little work is peculiarly opportune. It is well designed, and has been admirably executed. It seeks to bring together and present in convenient form the salient points of what has been already definitely ascertained with regard to the protozoa as parasites and pathogenic organisms. Although of much service and wide interest to biologists, the volume has been principally designed for the use of medical men, and certainly the author's desire that it should form a basis for considering recent and forthcoming work on the protozoa in disease may well be accomplished.

The work opens with a clear and concise description of unicellular organisms and the structure of the cell. Then follow well-arranged, lucid and adequate sections dealing with the principal parasitic protozoa, the gregarina, coccidia, and haemosporidia, neosporidia, and serumosporidia, flagellata, and ciliata. An interesting chapter deals with the diseases of the protozoa, while the concluding one deals with methods of investigation.

The value of the work is greatly enhanced by an excellent series of ninety-one figures, to which, in most instances, are appended luminous descriptions. Mr. Clarke proposes in a second part to collect the material regarding the part played by protozoa in pathogenic processes, and it may be hoped that he will not rest satisfied with a mere compilation, but will also publish the result of his own researches into this most perplexing and difficult, and yet most important, problem.

CLINICAL PSYCHIATRY. (b)

KRAEPELIN'S teaching has exercised world-wide influence. Dr. Defendorf may therefore well be congratulated on the successful way in which he has attained his desire "to make the teachings of Kraepelin in psychiatry accessible to American medical students and general practitioners, and, at the same time, to provide a full, concise, textbook, not only for the author's own classes in psychiatry in the Medical Department of Yale University, but as well for other American teachers who follow Kraepelin’s views."
We venture to think this volume will be welcomed by all English reading students. It appears to have been the author's intention to provide a complete translation of the sixth edition of Kraepelin's "Lehrbuch der Psychiatrie," but the volume in its abbreviated form certainly meets the needs of the student more satisfactorily than would have been possible if the original intention had been carried out.

The classification, terminology, and phraseology are Kraepelinian. The section on General Symptomatology forms an admirable introduction, and deals in a luminous and attractive manner with the various disturbances of perception, mental elaboration, emotional life, form and action, and the individual study of the different forms of mental disease much attention is devoted to the infection and intoxication psychoses. Kraepelin's work on alcoholism is generally recognised as of the greatest value and the important sections dealing with this form of toxic mental derangement are worthy of very careful study. A lengthy article appears on dementia praecox, the catatonic and paranoid forms being described with great care and much faithfulness. The presentation of the most important condition of dementia paralytica is lucid and trustworthy, and well illustrated by several interesting examples of the handwriting of paralytics.

Neurasthenia, the chronic nervous exhaustion, now so prevalent in this country and America, is excellent, and indeed, forms one of the most succinct and accurate descriptions to be found in any work.

The dementias dependent on organic defects are described, and the involution psychoses are concisely presented.

The general neuroses and constitutional psychopathic states are also dealt with, and defective mental development receives some notice.

Dr. Defendour's work has been well designed and excellently executed. It should prove popular with students of psychiatry and we have no hesitation in commending it to the serious attention of all physicians interested in this branch of clinical medicine.

The volume is admirably printed and the various illustrations are good.

**JERUM THERAPY. (a)**

Professor Hewlett's little manual is opportune in its appearing. In a few months it will be out of date, and we, or two or three, shall probably laugh at ourselves in its pages; but at the present it is an excellent presentation of our very limited knowledge on a vast subject which still remains wrapped in obscurity. The work is a concise account of the preparation of, and the treatment of disease with, antitoxins and antisera, vaccines and various other substances obtained from bacterial cultures. Directions are given for the making and testing of the various preparations; and in order to render the volume as serviceable as possible, the author has furnished short descriptions of such preparations as the typhoid extract of Jex, cancrin, and somewhat allied substances, together with notes on blood-transfusion and saline infusions.

The book opens with a valuable study of immunity, with a clear exposition of Ehrlich's views and "side chain" theory. The general methods for the preparation of the antisera are explained, and the general principles of their employment well set forth. Much attention is given to the diphtheria antitoxin, and the various anti-microbic sera are well described. The section on tuberculosis will be of considerable service.

The work has been planned to meet the needs of the scientifically-minded practitioner; but even for purposes of reference the volume will be of much value, and the various photographs add much to the verity of the various sections.

As already indicated, the subjects dealt with are necessarily too much or less in an elementary and transitional stage, and it is hardly fair to judge such a work by ordinary standards. The volume contains the difficulties and limitations with which the author has had to contend, he has succeeded beyond expectations.

**DISEASES OF WARM COUNTRIES. (a)**

Professor Schreber's work has very rightly been acclaimed the position of a classic, and should at last have appeared in English dress. The translation has been satisfactorily accomplished, and Mr. Cantlie has performed the task of Editor with judgment and discretion.

The whole work is most conveniently arranged. The general infectious diseases are first considered, then those arising from intoxications, and later the affections caused by animal parasites. The organic diseases are grouped together, as are also the cutaneous and local diseases, while the concluding section is devoted to what are termed the cosmopolitan diseases in the tropics.

The study of every disease dealt with practically forms a complete monograph, and the very extensive bibliography appended to each will prove invaluable for purposes of reference. A large number of plates present excellent illustrations of the chief symptoms. Some of the photographs we note are reproduced from *The Journal of Tropical Medicine*. A series of maps admirably indicate the geographical distribution of malaria, blackwater fever, beri-beri, leprosy, filariasis, and ankylostomiasis.

The work is to be looked upon as one for reference rather than for the purposes of a student's "handbook," but every practitioner whose duties call him to the tropics should see that a copy forms part of his outfit. It is much to be regretted that the publishers should have seen fit to disfigure the work by the insertion of advertisements concerning Scotch whiskies, toothpaste and the like; trade advertisements are disfiguring a work to scientific claims such as this.

**MCCAW'S AIDS TO INFANT FEEDING. (b)**

The subject of infant feeding has recently received a great amount of attention, so much so that its literature has become very extensive. The need for a small manual, containing in condensed form all the essentials of the subject, is therefore apparent, and this has been opportunely supplied by the well-appointed little volume before us. I am the entire work of the subject in nine short chapters. The author has made use of all the standard works on children's diseases and infant feeding, and he has given us more to read. He has written a handbook with a handy and thoroughly trustworthy guide, which will be of the greatest possible service to the practitioner or to the senior student, and calculated to save much valuable time in referring to larger and more wordy treatises. The author's name is a sufficient guarantee as to the accuracy of the statements he makes, but we should like to point out that, having read this book from cover to cover, we have not found anything that is incorrect. We can, therefore, unhesitatingly recommend our readers to become possessors of this excellent guide.

**BUXTON: ITS WATERS, ETC. (c)**

Among English health resorts, Buxton justly occupies a foremost place. It claims to be the highest town in England, and situated 1,000 feet above sea level. It is a pleasant town, with good hotels and public buildings, and a healthy climate. The water of the springs is said to be of great medicinal value, and is used for various purposes, such as bathing, washing, and drinking.

(a) "The Diseases of Warm Countries: A Handbook for Medical Men." By Dr. B. Scheube, late Professor at the Medical School in Hanoi (Japan). Translated from the German by Pauline Felce. Edited by James Cantlie, M.A., M.B., F.R.C.S., D.P.H., Surgeon to the Charing Cross Hospital for Injuries, London. London: John Bale, Sons, and Danielsson, Limited. 1902.

(b) "Aids to the Feeding and Hygiene of Infants and Children." By John McCaw, M.D., L.R.C.P., Senior Physician to the Belfast Hospital for Sick Children. "The Hospital and Its Work," pp. 130, cloth, 2s. 6d. London: Bailliere, Tindall, and Cox. 1903.

level, in the north-west corner of Derbyshire, in the tract of hill country called the High Peak, famous for its pure bracing air and invigorating climatic conditions. It is, however, to its water that it owes its chief distinction. In the present brochure the physiological action and therapeutic effects of the waters and baths are discussed and the means of application described. Indications and contra-indications are usefully summarised, and the synopsis of treatment is suggestive. A chapter is devoted to a consideration of accessories and adjuncts to spa treatment. Without being exhaustive the little work is interesting and practical, and should prove of service to those intending to send cases to Buxton. It is well arranged, clear in presentation, and well printed.

Obituary.

FRANCIS COOK, M.D. ED., M.R.C.P. LOND.
The death is announced at an advanced age of Dr. Francis Cook, one of the senior practitioners of Cheltenham. Dr. Cook, who was educated at Edinburgh and Paris, was University Gold Medallist at Edinburgh in 1835, receiving his M.D. degree in 1836, and in the same year he was admitted a licentiate of the Royal College of Physicians, Edinburgh. In 1866 he became a member of the Royal College of Physicians, London. He was a member of the Royal Medical and Hunterian Societies of Edinburgh, and was consulting physician to the Cheltenham General Hospital. Dr. Cook was the author of "A Treatise on Consumption," and contributed to the medical papers on the state of the military hospitals in Belgium, Prussia, and Italy.

The body of Dr. Joseph Muir Corbett, who was acting as surgeon to the American Line steamer "Astoria," has been found in the North River, New York. Nothing is known as to how the unfortunate gentleman met with his death. He was a graduate of the University of Glasgow, and at one time practised at Sanquhar, N.B., where for two years he acted as medical officer to the Royal Household at Balmoral.

Medical News.

Queen's College, Cork.
The recently issued annual report of the Queen's College, Cork, gives a concise account of the present condition of the college, and calls attention to its important movements in recent years as follows:—The number of students attending the college during the session was 854 matriculated and 4 non-matriculated. The number of new students was 58. Of these 49 came from the Royal University of Ireland, 5 from other colleges and universities, and 4 were non-matriculated. The number of first year medical students registered with the Medical Council shows that Queen's College, Cork, occupies, with Trinity College, Dublin, the second place as regards numbers. This increase in the numbers in Cork is the more remarkable, because there has been at the same time a diminution in the total number of students in all Ireland. During the session the work that has been done in the college has been solid, and the conduct of the students generally has been satisfactory. Towards the close of the session—on June 6th—the ordinary Visitation held every three years took place. Lord Justice Holmes presided at it. He stated to the Visitors some of the more pressing needs of the College, and gave an account of the work done since the last Visitation three years ago. The condition of the College was fully investigated, and a satisfactory state of things was disclosed. The statements made by Professor Corby and Professor Ashley Cummins concerning the facilities which Cork offers for clinical teaching merit the careful consideration of all interested in the spread of scientific medical education in Ireland. It was his duty to point out to the Visitors the urgent necessity which exists for the foundation and endowment of a Chair of Pathology. This important science is at present taught by Dr. Moore, who devotes his whole time to it, and is a most pressing one. It is impossible for scientific medicine to be properly taught at the present day, if the essential subject of pathology is neglected. No matter how competent the teacher may be who voluntarily offers to teach a subject, it cannot be regarded as anything else than neglected when there is no proper equipment for teaching, and no salary attached to the post of teacher.

The Royal (Dick) Veterinary College, Edinburgh.
The eighty-first Session of this College will open on October 6th, and on the following day, the inaugurations of the new buildings will be opened by Dr. M. Kendrick, F.R.S., Professor of Physiology in Glasgow University. At one time a Professor in the Dick College, Professor M. Kendrick has taken a deep interest in Veterinary education, and is one of the trustees on the estate of the late Miss Mary Dick, from which the college is to derive a substantial addition to its funds and equipment. Further particulars will be supplied to the address to be delivered by Professor M. Kendrick. This fine old college, which has so long maintained a leading position, and has sent out many eminent veterinarians, need not of whom have recently entered the veterinary profession, would seem to have before it a career of still greater distinction and usefulness, for in addition to the benefit that accrues to it from Miss Dick's estate—over £20,000—it has to be strengthened by a gift of £5,000 from Mr. A. I. MacCallum, of Edinburgh, an old and well-known student of the College. With these handsome additions to the property already possesses, the Royal (Dick) College will become the most handsomely endowed, and most fully equipped Veterinary College in any English speaking country, and this too without any subscriptions from Parliament or other public source.

Disappearance of Miss Hickson, M.D.

PAINFUL interest has been excited by the disappearance of Miss Sophie Hickson, who had undertaken to act as locum tenens at the Royal Free Hospital for one of the lady resident doctors. She left the hospital after the morning's work at noon and as she failed to put in an appearance, her family were informed of her disappearance. Visits to all the relatives and friends of the lady in London have failed to clear up the mystery, and no trace of her has been found. Her family have communicated with Scotland Yard, the officials of which are now also actively engaged in the search. The greatest sympathy is felt for the lady's family in this period of suspense.

Society of Apothecaries of London.
The following candidates passed during August in:—

Surgery.—H. H. Clarke (Sections I. and II.), A. N. Collier (Section II.), M. B. Dawson (Section II.), F. Hansen, J. M. King (Sections I. and II.), N. O. Roberts, (Section I.), A. C. Stark (Sections I. and II.).

Medicine.—A. H. Falkner (Section I.), A. C. Stark (Sections I. and II.).

The L.S.A. diploma was granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery:—H. H. Clarke, A. N. Collier, J. M. King, and A. C. Stark.

SMALL-POX is diminishing at Cambridge. During the past seven days only four fresh cases have been reported.
NOTICES TO CORRESPONDENTS.

Aug. 26, 1903.

Hull City and County Lunatic Asylum.—Second Assistant Medical Officer, Salary £126 per annum, with board, lodging, and attendance. Applications to the Chairman of the Asylum Committee, care of the Town Clerk, Town Hall, Hull.

The Hartpury Hospital.—House Surgeon £100 per annum, with board, washing, and lodging. Applications to Robert M. Lockwood, Senior Assistant Secretary, 9, Rue de Courcelles, Paris.

Devon County Asylum, Exeter.—Third Assistant Medical Officer. Salary £152 per annum, with board, lodging, washing, and attendance. Applications to the Medical Superintendent.

Parish of Barn.—Medical Officer and Public Vaccinator. Salary £119 per annum. Applications to Thomas H. Lazenby, Clerk.

Ballinamoon Union.—Medical Officer. Salary £100 per annum; also to act as Medical Officer of Health, at a salary of £20 per annum. Immediate application to be made to J. B. Chisnall, Clerk of the Union. (See adv.)

Ballinasloe Union.—Medical Officer. Salary £130 per annum, together with Registration and Vaccination Fees; also to act as Medical Officer of Health at a salary of £25 per annum. Applications to J. G. Hill, Clerk of the Union. (See adv.)

Clitheroe Union.—Medical Officer. Salary £105 per annum and £10 per year as Medical Officer of Health; with usual Registration and Vaccination Fees. Applications to F. King, Clerk of the Union. (See adv.)

Locum Tenens, to take charge of Dispensary District and Private Practice, terms six guineas per week. Applications to Dr. Macdormott, Bailhardiner, Co. Roscommon. (See adv.)

Suffrages.

FRASER.—On August 8th, at St. George's Terrace, Trowbridge, the Rev. James Fraser, M.D.

HODGSON.—On August 18th, at Westcliff-on-Sea, the wife of Victor J. Hodgson, M.R.C.S., L.R.C.P., D.P.H.Camb., of a son (stillborn).

Marriages.

FARINE—WRIGHT.—On August 20th, at Holy Trinity Church, Southport, Edward Ferrie M.D., of Stone, Staffs, to Elizabeth Haywood (Little), of the late Mr. J. A. Prestwich and Mrs. Wight, of 1 Belgrave Road, Southport.

WILLIAMSON—MACKINNON.—On August 20th, at the United Free Church, Bombay, John Rutter Williamson, M.D., of Miraj, Bombay Presidency, sixth son of Dr. William and Jane Williamson, of Summer, to Edith Eliza, elder daughter of Rev. Dr. Mackinnon, LL.D., R.A. Principal of Wilson College, Bombay, and 1st. Chancellor of the University of Bombay.

OPERATIONS.—METROPOLITAN HOSPITALS.

WEDNESDAY.—St. Bartholomew's (1.50 p.m.), University College (2 p.m.), Royal Free (2 p.m.), Middlesex (3.30 p.m.), Charing Cross (3 p.m.), St. Thomas's (2 p.m.), London (2 p.m.), King's College (2 p.m.), St. George's (2 p.m.), National Orthopaedic (10 a.m._2 p.m.), Samaritans (9.30 a.m. and 2.30 p.m.), Oxford Street (8.30 a.m.), Great Northern Central (2.30 p.m.), Westminster (1 p.m.), Bart's Hospital (10 a.m._2 p.m.), Metropolitan (9 a.m.—2 p.m.), London (2 p.m.), St. Mary's (4.30 p.m.), London (2.30 p.m.), Charing Cross (2 p.m.), Great Northern Central (2 p.m.), St. George's (2 p.m.), Metropolitan (9 a.m.—2 p.m.), St. Mary's (2.30 p.m.), Sobo Square (2 p.m.), North-West (2 p.m.), Chelsea (2 p.m.). Great Northern Central (8.30 a.m.—2 p.m.), Metropolitan (2.30 p.m.), London (2.30 p.m.), St. Mark's (2.30 p.m.), Samaritans (9.30 a.m. and 2.30 p.m.), Thames, Great Southern (2.30 p.m.), Guy's (1.30 p.m.).

FRIDAY.—London (2 p.m.), St. Bartholomew's (1.50 p.m.), St. Thomas's (8.30 p.m.), Royal Free (8.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.50 p.m.), Charing Cross (8 p.m.), St. George's (8 p.m.), King's College (8 p.m.), St. Mary's (8 p.m.), Charing Cross (8 p.m.), St. Mary's (8 p.m.), Samaritans (10 a.m._9.30 a.m.), Cancer (2 p.m.), Chelsea (2 p.m.), Great Northern Central (2.30 p.m.), West London (2.30 p.m.), London (9.30 a.m.—2.30 p.m.), Thames, Great Southern (9.30 a.m.), City Orthopaedic (2.30 p.m.), Sobo Square (2 p.m.).

SATURDAY.—Royal Free (8 a.m.), Middlesex (10 a.m.—2 p.m.), St. Thomas's (2 p.m.), University College (9.15 a.m.), Charing Cross (2 p.m.), St. Mary's (1 p.m.), Thames, Great Southern (9.30 a.m.), Guy's (1.30 p.m.).

MONDAY.—London (2 p.m.), St. Bartholomew's (1.50 p.m.), St. Thomas's (2 p.m.), Middlesex (1.50 p.m.), Westminster (3 p.m.), St. Mary's (3 p.m.), Samaritans (Gynaecological, by Physicians, 2 p.m.), Sobo Square (2 p.m.), Royal Orthopaedic (2 p.m.), City Orthopaedic (4 p.m.), West London (2.30 p.m.), Great Northern Central (2 p.m.), London (9.30 a.m.—2.30 p.m.), Thames, Guy's (1.30 p.m.).

TUESDAY.—London (2 p.m.), St. Bartholomew's (1.50 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (3.30 p.m.), Westminster (3 p.m.), St. Mary's (3.30 p.m.), Samaritans (Gynaecological, by Physicians, 2 p.m.), Sobo Square (2 p.m.), Thames, Great Southern (9.30 a.m.—2.30 p.m.), Thames, Guy's (1.30 p.m.).

Disclosures.

CORRESPONDENTS requiring a reply in this column are particularized, and requested to make use of distinctive signa-} ture or initial, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

G. S. A.—The symptoms you mention are indicative of arrested mental development with a lack of the moral sense. The only thing to be done is to be kept under medical observation, due provision being made for her education and training within the limit of her intellectual powers. She should under no circumstances be left to herself, and it is advisable to induce her promptness to introspection.

DOUBTFUL.

An exchange reports that a man in South Dakota was operated upon for appendicitis, when it was found that he had been swallowed whole grains of wheat, which had sprouted in the bowl, and the Herissant was at work on the wheat.

Dr. H. N. G. (Ponsonby).—We will bear your request in mind, and will inform you with you should an opportunity present itself.

P. & C.—Instances have been reported in which several cases of acromyocytosis have been observed in the same family, which sufficiently point to infection. As, however, it is difficult to eliminate the possibility of a common source of contamination, and as our knowledge of the actual process by which the disease is set up is imperfect, it would not be wise to dogmatize on the subject. We hope to publish a case of " family acromyocytosis" in an early issue.

THE ANTIDOTE.

Nurse (excitedly)—Oh, doctor, I have just given the patient a teaspoonful of what shall I do? Doctor (calmly)—Give him a blotter to eat away the effects.

Dr. BARRAN (Algiers).—We understand that the negotiations have been broken off, but this does not in any way dampen the scheme. We will refer the matter to our local correspondent, who may be in a position to give fuller information as to the present position.

M. S. R.—We have made inquiries, but gather that no such instrument has yet been produced; the device might, however, place you in communication with a manufacturer, who will doubtless be pleased to advise on the practicability of your ideas.

Appointments.

ELLIS, E. H., M.D.Durh., Certifying Surgeon under the Factory Act for the Synton District of the County of Leicester.

MACDONALD, H., M.B., Ch.E.D., R., House Physician at the City of London Hospital for Diseases of the Chest.

MACDONALD, R. M., M.D., House Physician, President of the Wymorsh Division of the County of Dorset.

O'BRIEN, A. R.M.C., L.R.C.P.Lond., Certifying Surgeon under the Factory Act for the Hunscombe District of the County of Devon.

Vacancies.

Staffordshire General Infirmary, Stafford.—House Surgeon. Salary £120 per annum, with board, lodging, and washing. Applications to the Secretary, Richard Battle, 7, Maybrick Road, Stafford.

Liverpool Infirmary for Children.—House Surgeon. Salary £100 per annum, with board and lodging. Applications to the Hon. Secretary.

Birmingham and Midland Eye Hospital.—Resident Surgical Officer. Salary £100 per annum, with board and attendance. Applications to the Chairman of the Medical Board.

Bury Infirmary.—Junior House Surgeon. Salary £20, with board, residence, and attendance. Applications to the Hon. Secretary.

The Cambridge, &c., Asylum.—Second Assistant Medical Officer. Salary £20 per annum, lodging and washing. Applications to J. Mungay Francis, Clerk to the Visitors, 18 Emmanuel Street, Cambridge.

Staffordshire General Infirmary, Stafford.—Assistant House Surgeon. Salary £50 per annum, with board, lodging, and washing. Applications to the Hon. Secretary.

Barnwood Hospital for the Insane, Gloucester.—Junior Assistant Medical Officer. Salary £150 a year, with board and lodging. Applications to the Medical Superintendent.

East London Hospital for Children and Dysphasia for Women, Shadwell.—Assistant Medical Officer. Salary £150 per annum, with furnished apartments, washings, and attendance. Applications to Harry Last, the Clerk, East London Hospital. Kent and Canterbury Hospital.—House Physician. Salary £90 a year, with board and lodging. Applications to the Secretary.
Original Communications.

THE UPPER RESPIRATORY TRACT AS A SOURCE OF SYSTEMATIC INFECTION. (a)

By F. Dr. HAVILLAND HALL, M.D., F.R.C.P.,
Physician to the Westminster Hospital, &c.

It was pointed out that no branch of medicine had greater advance been made than in the knowledge of the methods by which diseases were propagated, and that it was only since the discovery that many if not most, constitutional affections depended on the presence of bacteria that attention had been directed to the upper respiratory tract as a source of infection. Dr. Hall alluded to a paper on five cases of typhoid fever read by Dr. Watson Williams at the meeting of the British Medical Association in 1894, in which he adduced evidence to support the view that the respiratory tract was the source of primary infection in one of the cases. Dr. Hall had had one hospital case in which the disease appeared to have started in the larynx. Though typhoid fever is almost invariably propagated by means of the stools and urine, there is sufficient evidence to show that the Klebs-Löffler bacillus may find its way into the system through the respiratory tract. This is the more likely to be the case if the vitality of the laryngeal mucous membrane is lowered owing to previous inflammatory mischief. These cases confirm Budd’s view that under certain conditions typhoid fever was infectious, and they should lead to the expectoration being disinfected.

Though definite evidence is wanting on the subject, clinical experience points conclusively to the poison of measles and whooping-cough being received via the respiratory tract. In influenza Dr. Hall has seen many cases in which the trouble has appeared to start in the naso-pharyngeal space, and many instances the opinion that adenoid vegetations and enlargement of the faecal tonsils rendered the individual more liable to contract influenza and many other infectious diseases. In diphtheria there can be no doubt that, in the great majority of cases, the Klebs-Löffler bacillus implants itself in the tonsil, and practically enters its circulation at the erosion of the epithelium. At the onset the disease is a purely local one, the secondary symptom being due to the absorption of toxic materials secreted by the bacilli during their growth. Dr. Hall mentioned a case of diphtheria in which he was uncertain about the diagnosis until, on making a rhinoscopic examination, he found the characteristic deposit in the naso-pharynx. This localisation is more frequent than is generally recognised, and it is probable that some of the cases usually regarded as primary nasal diphtheria may really commence in the naso-pharynx, and then the nose is affected by extension. In the primary laryngeal, form clinical evidence is in favour of the view that the Klebs-Löffler bacilli enter the system through the laryngeal mucous membrane. Usually, however, the larynx is affected by extension from the pharynx. That the nose plays an important rôle in the diffusion of diphtheria is certain. During an epidemic children suffering from nasal discharge mixed with blood, and especially if they have enlarged cervical glands, should be isolated and the secretion examined bacteriologically. Diphtheria is doubtless occasionally spread by a case of nasal diphtheria which has been overlooked, or by the persistence of the Klebs-Löffler bacillus in the nasal secretion of a patient who has had diphtheria, but who has been considered convalescent and free from infection. It has also been shown that the nasal and oral secretions of apparently healthy persons who have been in contact with diphtheritic patients may present the specific bacillus. Dr. Hall mentioned two cases in which the use of the galvanocautery to the nasal mucosa, scarlet fever has attacked the individual, and he was of opinion that the germ entered the system through the wound caused by the galvanocautery. Lacunar tonsillitis is another disease which has resulted from intra-nasal cauterisation. The conclusions to be drawn from these cases is the advisability of abstaining from operative procedures on the nasal mucous membrane in persons liable to be exposed to septic and infectious diseases.

The intimate connection between the throat and acute rheumatism was insisted on, as shown by the frequency with which tonsils precede or accompanies an attack of acute rheumatism. Clinically, acute rheumatism may be regarded as an infectious disease which runs the course of an attenuated pyaemia, the infection entering the system in a large number of the cases through Waldeyer’s pharyngeal ring, especially the faecal tonsils. The inflammatory reaction in the tonsils, to which the name of lacunar tonsillitis is given, may be regarded as the evidence of the local action of the microorganism causing the disease. Another view
is possible—viz., not to regard the tonsillitis as in any way due to rheumatism, but as affording a mode of entrance into the system of the germs which give rise to rheumatism. Dr. Hall then read the notes of two cases to show that septic and pyemic processes may be the result of infection through the upper respiratory tract. In these cases great benefit resulted from the prompt use of antistreptococcic serum subcutaneously. The important part played by chronic nasal affections in the production of facial erysipelas was insisted on, and it was suggested that not only erysipelas, but also other conditions, such as angina Ludovici, phlegmon of the pharynx and larynx, may result from infection through the upper respiratory tract.

The occasional occurrence of primary nasal tuberculosis, and even the rarer occurrence of primary laryngeal tuberculosis, point to the possibility of systemic tuberculous infection via the upper respiratory tract. One of the most important advances which has been made of late years in regard to the diffusion of tuberculosis is the recognition of latent tuberculosis of the tonsils.

Until quite recently it was generally held that the tonsils were but rarely affected with tuberculosis, and then only superficially as the result of extension from pharyngeal tuberculosis, but Dr. Hugh W. Walsham has shown that out of thirty-four consecutive post-mortem cases the tonsils were found to be more or less tuberculous in twenty. The discovery of the liability of the tonsils to tuberculous infection has thrown quite a new light on the subject of tuberculous disease of the cervical glands, and emphasises the importance of removing enplarcted and chronic tonsils. The tonsils probably become infected by tubercle bacilli in children, who crawl about and get their hands covered with dust and dirt, and then infect themselves by sucking their fingers. Some bacilli may gain access to the tonsils in swallowing tuberculous milk, or, in respiration, the air containing the bacilli may deposit them on the tonsils. Not only are the faucial tonsils the seat of primary infection by the tubercle bacillus, but also the pharyngeal tonsil may be the first part affected. The recognition of the tuberculous nature of some adenoid vegetations and the possibility of the system becoming infected through them should constitute an additional reason for the prompt and complete removal of these growths.

THE CLASSIFICATION OF INSANITY. (a)

By CHAS. MERCIER, M.B., M.R.C.P., F.R.C.S., Lecturer on Neurology and Insanity at the Westminster Hospital.

After drawing attention to the great multitude of existing classifications, and the fact that not one was generally accepted, and pointing out how essential a satisfactory classification was to systematic thought upon the subject, the speaker proposed a classification based upon the duration of the period over which the case was contemplated. If we regarded the case as it existed at one time, without considering its previous or subsequent stages, without regard to its causation or result, we arrived at what he styled the form of the insanity; while if we took account of the whole progress of the malady, its causes, its progress through successive stages, and its termination, we then ascertained what he called the variety of the insanity, which thus corresponded in measure with what is ordinarily termed a disease, while the form of the insanity stood on a level with the revolution and dyspepsia, as a symptom merely. Taking mania and melancholia as common instances of forms, the speaker showed that they not only appeared again and again in different varieties, but that they might alternate, and often co-existed in the same case. When so co-existing they did not form a combination of two insanities, as pneumonia occurring in Bright's disease constituted two independent maladies, but a single insanity.

Forms of insanity were either single states, or were antithetic couples, and stress was laid on the importance of comparing mental states with mental states, and modes of conduct with modes of conduct. Mania and melancholia, for instance, which were so constantly compared and considered antithetic to each other, were, in fact, not comparable with one another, the one being a mode of conduct, the other a state of mind. The true antitheses were mania and stupor, depression and exaltation. In addition to these, other antithetic couples were, obsession and facility, suspicion and over-trustfulness. The single forms of insanity were delusion, confusion, moral perversion, and weak-mindedness, the latter term being understood to include degradation of conduct as well as of mind, and to be equivalent to the Jacksonian term "reduction." That is to say, it meant the deficiency of certain higher modes of both thought and action, accompanied by overaction of lower modes of both, permitted by the defect of the higher faculties. This, it was pointed out, was the common form of all insanity, and was exhibited in greater or less degree by every case.

Varieties of insanity took rank with diseases as forms of insanity took rank with symptoms. The former come into view when we contemplate insanity not as it exists from moment to moment from hour to hour, but when we regard its whole history from beginning to end, combining the history with an assigned cause and tracing it to a definite termination. The type of variety of insanity is general paralysis, and many other definite varieties are recognised, such as the insanity of alcohol, of epilepsy, of the times of life, of reproduction, &c.

Intermediate between forms and varieties stands acute insanity, which is a variety in respect that it may exhibit a combination or succession of two or more forms, while it may be regarded as a form in that it may exist in several other varieties: the apparent anomaly is explained by the duration of time over which the contemplation of the malady extends; while forms strictly so-called are identifiable in a view which extends over minutes, and varieties strictly so-called are not discriminable except by contemplating a course extending over weeks, or months, or years. Acute insanity is to be recognised by a course extending over hours or days. Six types of acute insanity were distinguished: maniacal, melancholic, suicidal, sexual, resistant and stuporous, marked by the prominence of one or other of these characteristics; but the inclusion of all these types under a single head was

(a) Abstract of paper read at the Psychological Section of the Medical Association at Swansea, August 1st, 1885.
justified not only by the general similarity of the course, but by the presence in all cases of many common features, including tendency to suicide, to excitement, to sexual irregularities, to refusal of food, to faulty and destructive habits, and to impulsive outbursts.

The outspokened for this mode of classification that it was natural, in that it corresponded with the actual facts; that it was easily applied in practice; and that where its divisions are not clearly distinguished it faithfully reproduces the similar want of distinction that exists in the thing classified.

HISTORICAL SURVEY OF THE STUDY OF ACUTE CEREBROSPINAL MENINGITIS. (a)

By CECIL WALL, M.A., M.D.Oxon., M.R.C.S.

In the earliest medical literature no evidence can be found that inflammation of the covering of the brain was looked upon as a disease; that the disease then existed may be inferred from descriptions of conditions which, in all probability, represented the secondary effects. The year 1768 marked the dawn of a new era in the study of cerebral disease. Robert Whytt, of Edin-burgh, recorded his memorable observations upon acute hydrocephalus; most, if not all, of his cases were due to this disease, but he thought that the determination of the fluid to the ventricles was primary and the cause of the disease. His description of the clinical characteristics of the condition and their distribution among the symptoms form the boundary between chaos and order in the history of intra-cranial inflammatory disease. In conformity with the conception that the effusion was primary and all-important, he employed the title "acute hydrocephalus," a term which continued in general use until 1825, when Senn urged the propriety of substituting the word meningitis.

The work of Whytt was soon followed by that of other investigators. Quin, of Dublin, in 1780 is to be credited with the suggestion that the effusion in the ventricles was secondary, but he went no further than to suggest this as a cause a morbid state of the blood in the brain. In the same year Edward used the term "Hydrocephalus Internus," in which he states that "it is probable that the effusion of water into the ventricles of the brain is the effect of inflammation of the meninges." He quotes Whytt, and credits Quin with the recognition of the secondary nature of hydroce- phalus, but does not seem to have been familiar with the work of Ford.

Thus at the close of the eighteenth century it seems to have been generally recognised that acute internal hydrocephalus was secondary to some antecedent meningeal or vascular disturbance. At the commence- ment of the nineteenth century inflammatory con- ditions of the cerebral meninges came to be recognised as associated with certain symptoms.

Herpin, in 1803, a surgeon with the army of the Rhine, introduced the term meningitis to express in- flammation of the meninges. The cases that he de- scribed were secondary to fracture of the skull, and consequently unimportant from the point of view of this research. His analysis of symptoms, however, and the contrast with those of the secondary encephalitis, which apparently followed concussion without fracture of the skull, formed a useful basis for those who subsequently investigated the primary form of the disease.

Herpin's seems to have been the first attempt to associate definite symptoms with inflammation of the meninges apart from hydrocephalus. In 1806 there occurred at Geneva an epidemic of a disease with which the physicians of the time were not familiar; it was described by Vieuxseneux, under the title "Meninge, non-contagieuse." This disease occurred in several members of the same household, but appa- rently was not communicable by personal contact. It affected chiefly children and young adults, nine-tenths of the cases being under thirty years of age, and was not particularly dangerous. The onset was sudden, with headache, vomiting, and delirium, and it might prove fatal in twenty-four hours. In the cases that were not fatal the recovery was prompt, and the longest duration being fourteen days. Unfortu- nately the report of the post-mortem appearances is unsatisfactory, and in the allusions made to the autopsies there is nothing to suggest that purulent inflammation of the meninges was ever found.

It has, however, been usually accepted that this is the first account of what is now known as epidemic cerebro-spinal meningitis. Mathey gives an account of one autopsy which he conducted for Vieuxseneux, and describes a gelatinous condition of the meninges which may possibly be taken to indicate the presence of meningitis. In the same year H. N. and H. E. Plagmann described an outbreak of a similar disease which occurred in Medfield, Massachusetts, giving the symptoms of the disease and the result of five autopsies. In 1809 a committee, consisting of Drs. Jackson, Warren and Welch, presented a report to the government concerning this epidemic. They concluded that, though it was termed "spotted fever," yet "the petechiae were secondary and not essential to the disease;" it was a fever of the "greatest severity, the death rate being 50 per cent, especially on those within the cranium." They suggest- ed that this inflammation was commonly crys- liphotous in nature. The Geneva and the Medfield epi- demics drew attention to a disease then wholly un- recognised, and, though there can be no certainty that it was the same as that now known to be caused by the diplocooccus intracellularis, yet the investigations that followed laid the foundation for our subsequent knowledge of the subject.

In 1814, Bietz, in a Paris thesis on acute idiopathic phrenitis, complained that the term was commonly, though wrongly, applied to inflammation of the arachnoid. Apparently he was the first who recog- nised idiopathic meningitis as a separate disease, and realised that acute hydrocephalus may follow infam- mation of the arachnoid.

In 1815, Gollis, in a thesis on acute hydrocephalus, defined dropsy of the head and brain as "a collection of serous, lymphatic, or puriform fluid, or a mixture of these, in the cavities of the cranium or in those of the brain." This he said might be "(1) External—that is, either between the scalp and pericranium, or be- tween the pericranium and cranium. (2) Internal— that is, (a) between cranium and dura mater; (b) between dura mater and pia mater; (c) between pia mater and brain; (d) in the cavities of the brain. (3) Combined, external and internal.

From the description he gives of the cases it seems clear that he dealt with cases of acute meningitis and of idiopathic meningitis, but also with cases of secondary meningitis, due to fracture of the skull, and possibly also to middle-ear disease. In one case in which death resulted from convulsions during an attack of whooping-cough, the record of the autopsy scarcely seems to justify his diagnosis of acute hydroce- phalus, seeing that apparently there was no menin- gitis and no excess of fluid in the cerebral ventricles. He distinguished two groups of cases which could be recognised by the mode of onset. In the first group the symptoms developed gradually, and apparently closely corresponded to those of what is now recognised as tuberculous meningitis. The second group was characterised in the symptoms and mode of onset the posterior, basic meningitis of recent years; the disease, he says...
commenced suddenly with headache, vomiting, fever, and pains in the back and limbs, and of the peculiarities that the pons vermis in this form is better than in the first group: the duration he gives as between thirteen and twenty-one days, and recognises four stages corresponding to the pathological conditions of convulsions and coma. The headache occurring early and a disturbance of the mental processes, often resulting in delirium occurring before the third day; vomiting generally occurred at the onset, and sometimes continued until death. The pulse was slow and the skin of the chest sometimes over 100: he had had a temperature, but it was not so high; strabismus was frequently noted, and the convulsions and coma were often present only as a transient phase of the disease. The disease was frequently of short duration, but when it did occur, the symptoms were often severe. The patient was usually unconscious, and the pulse was weak and rapid. The pulse was commonly rapid throughout, and did not conform to Whytt's stages.

They held that meningitis in children was, in the vast majority of cases, associated with the tuberculous diathesis, but that a simple form occurred, especially among the newly-born. They believed that sometimes epidemics of simple meningitis arose, agreeing in this point with Guersant, and also quoting him. These cases were few, and the number of meningitis cases was small, but the patients were often blind. Convulsions were only present in two out of the six cases. The duration varied between one and six days, on average two days.

The diagnosis generally had to be made from tuberculous meningitis, and in a table of the chief distinguishing features it is shown that in simple meningitis the onset is more sudden; the headache is more severe; the pulse is more rapid, and the duration much shorter. The pulse is rarely less than 100, and does not conform to Whytt's stages.

Regarding the cause of the ventricular effusion, he expressed a strong belief that it is due to inflammation of the lining membrane of the ventricles. Considering these statements, it seems necessary to suppose that in some cases of acute meningitis not due to the Baccillus tuberculosis; moreover, his deductions seem closely in accord with the results of earlier research. In agreement with Cohn, in 1827, and Senn, in 1834, he recognizes the term "meninitis" in reference to "acute hydrocephalus," and so began a new chapter in the description of meningitis.

During the next twenty years research was directed toward the separation of different varieties of meningitis. In 1827 Guersant recognised a granular form of meningitis, but was not certain that the granules were really tubercles. Papovine, in 1830, speaks of tubercles causing ataxia and meningitis, but Gerhard, in 1834, was the first to satisfy his contemporaries, by an exhaustive research, that the granules were identical with tubercles. Guersant, in 1839, in an article on meningitis of the brain, and in his "tuberculous meningitis," makes a distinction between tuberculous meningitis and the non-tuberculous or simple form; the latter, he says, is not uncommon among the newly-born, and he quotes Albert (1830) to show that it may possibly occur with an epidemic distribution: neither his work, however, nor Albert's, was based on any extensive investigation of the post-mortem appearances.

In a text-book of diseases of children, published in 1834, by Ribbert and Barthez, is to be found the first accurate description of simple non-tuberculous meningitis, the account of the morbid anatomy being based upon the examination of six cases. They recognized three anatomical forms of meningitis: (1) Inflammation of the pia mater with tuberculous granulations in the meninges. (2) Inflammation of the pia mater without any tuberculous granulations in the meninges, but with general miliary tuberculosis of other organs. (3) Inflammation of the pia mater without any tuberculous granulations in any organ of the body. The first two groups represent well-known varieties of tuberculous meningitis; the third group characterised by pus upon the convexity of the brain, and also at the base, especially near the large vessels, with a slight amount of turbid fluid in the ventricles. In the one case in which this was examined there was an acute spinal meningitis.

They further endeavoured to differentiate between idiopathic meningitis and that form which was secondary to an antecedent pneumonitis or typhoid or other disease. The symptoms of the meningitis were the same, the treatment varied. They operated upon the head, and the drainage of the cerebrospinal fluid, which might end in death at a later period of the disease, or in recovery after a protracted convalescence. He drew attention to the head retraction and opisthotonos, which was common, and which does not seem to have been noticed previously by Meyriez and others. This is a distinction for post-mortem examination upon any children; in the adults he found lymph upon the vertex of the brain, and "the most unequivocal marks of inflammation at the base of the brain." The next important contribution to the study of meningeval disease was made by Hilton in his lectures on "Rest and Pain," where he suggested his famous mechanical theory for the production of internal hydrocephalus. He supposed that owing to a congenital condition, or to previous inflammation in that region, the foramen of Magendie became blocked, so that the draining of the cerebrospinal fluid from the ventricles was prevented. The probability of the explanation has been discussed elsewhere; it was so specious, and emanated from so high an authority, that it has loomed largely, perhaps too largely, in the writings of subsequent investigators.

Later, in 1865, Burdon Sanderson presented a report to the Privy Council concerning an epidemic of cerebrospinal meningitis then prevalent in the region of the River Vistula; the third group containing an account of both the clinical characters and of the morbid anatomy of the disease, with an investigation of its epidemiology, forms the first trustworthy standard to which reference can be made in determining the identity of outbreaks to which a similar name has been applied.

Loeb, in 1867, again put forward the view that the effusion may be the result of thrombosis of the veins of Galen.
applied. He established an important point in that he showed that "no facts were met with in the course of the inquiry which afforded ground for believing that epidemic meningitis was capable of being communicated by personal intercourse." In times when bacilli did not as yet exist, and before there was any attempt to determine the etiology of a disease, evidence of transmission by contangion was an important point for investigation; meningitis, it is now admitted, may be due to infection by several different organisms, and it is quite probable that the mode of infection may be different with different varieties. Sanderson showed that one variety of meningitis at least could be epidemic, though not necessarily of a spreading character, and it is probable that the clinical characters and in morbid appearances, evidence concerning the mode of spread must weigh heavily in forming a judgment concerning the nature of two independent outbreaks.

Webber, writing in 1866, in reviewing all the past literature concerning epidemic meningitis, concludes that "it is only epidemic typhus, wherein, from some cause, the cerebro-spinal system is the principal seat of the attack." The clinical characters of the cases recorded by Sanderson do not suggest any relation to typhus, and the absence of evidence of spread by contagion seems to indicate that such a relationship is improbable.

Murchison admitted that meningitis might be a complication of typhus; it seems a natural deduction that some of Webber's cases, at least, may have been due to typhus erroneously, and that they did not belong to the same group as Sanderson's cases, but were due to some other infection, possibly that of typhus.

Since this time, however, epidemic cerebro-spinal meningitis has been recognised as a distinct and independent disease, with characteristic symptoms. It was from cases belonging to this type that Weichselbaum, in 1887, isolated the organism which bears his name, and which is supposed to be the infecting agent.

In 1878, Gee and Barlow published a paper concerning the cervical opisthotonos of infants, but although they suggested its possible relationship with epidemic meningitis, they were unable to find evidence of transmission by contagion, and did not consider that the disease occurred with sufficient frequency to deserve the title of epidemic. In all, they investigated twenty-four cases, the oldest of whom was aged nine months; the onset, they said, might be sudden or gradual, and the retraction of the head, which suggested the name, was associated with rigidity of the limbs and sometimes with epileptiform convulsions. Sometimes embolism of the head occurred. At the autopsy the meningitis was found without any evidence of tuberculous infection; in two cases spinal meningitis was present, in one there was internal hydrocephalus, and in five a small effusion into the ventricles.

These cases seem closely allied to the condition described by Rillett and Barth at simple meningitis; retraction of the head, however, had not been previously noticed as a prominent feature of the disease, except by Gillkrest in the epidemic at Gibraltar. These cases have more recently been included under the heading of posterior basic meningitis.

With the development of methods of bacteriological research a new epoch in the study of meningial disease was inaugurated.

In 1882, Koch, by his discovery of the tubercle bacillus, rendered it possible to be certain concerning the etiology of tuberculous meningitis. During the next few years numerous authors described organisms which they considered to be the causal agents of epidemic meningitis, but it was not until 1887 that an attempt was made to establish the importance of the organism isolated by Weichselbaum from the cerebro-spinal fluid of certain cases of cerebro-spinal meningitis. Weichselbaum dealt with eight cases, and the disease is described in the "Medical Press," dealing with the disease from all aspects—clinical, pathological, epidemiological, and historical.

The cases with which Weichselbaum dealt were sporadic, and from the brief clinical report they seem to have conformed to the type investigated by Sanderson on the lower Vistula, and not to the type described in some epidemics where the hemorrhagic tendency and the involvement of the meningeal structures are so suggestive of a septicemic condition.

About this time (i.e., 1886 and 1887) Netter and Foà and Ufferedziu isolated the pneumococcus from cases of epidemic cerebro-spinal meningitis.

Both the pneumococcus and the meningococcus have been frequently isolated by other observers since that time; it is unquestionable that both organisms may and do rise to cerebro-spinal meningitis, and it is only admitted now that they are distinct. It has not, however, been finally settled whether the epidemic form of the disease is always due to infection by the same organism. Differences in the clinical manifestations suggest that all epidemics do not claim the same infective agent.

In 1891 Wynter showed that in cases of tuberculous meningitis the ventricles could be drained by opening the spinal theca in the lumbar region, thus casting doubt upon the truth of Hilton's mechanical theory of the production of hydrocephalus. In the same year Quincke described the process of lumbar puncture, and it was to be of such subsequent value in determining the nature of the bacterial infection.

In 1893 Merton demonstrated that hydrocephalus might exist without closure of the foramen of Magendie, and thus supported Wynter's objection to Hilton's theory.

In 1897 Dr. Walter Carr published a long and accurate description of the posterior basic meningitis of infants, entering fully into the clinical aspect and the distinguishing features of this pathological condition which gave rise to the various symptoms. This is the first important paper that deals with this subject since the publication of Gee and Barlow's cases; unfortunately, it lacks unfortunate confirmation. This was supplied in the following year by Barlow, Lees, and Still in their article in Allbutt's "System of Medicine," in which, in addition to an accurate clinical account of the condition, is recorded Still's observation that an organism closely resembling, if not identical with, Weichselbaum's meningococcus was the infecting agent.

Microscopic bacteriological evidence was supplied showing the probability of the relationship of posterior basic meningitis to epidemic meningitis, a relationship which on clinical grounds had been surmised by previous authors.

In the same year (1898) appeared the report of Counselman, Mallory, and Wright, concerning a number of cases of cerebro-spinal meningitis, from many of which they had isolated an organism which, in its morphological and cultural reactions, they considered to be identical with Weichselbaum's diplococcus. The frequency of occurrence of the disease so far transcended the normal that the adjective "epidemic" seemed justified. There was no evidence of spread by contagion, and the clinical accounts of the cases show that they were similar to those described by Sanderson, and to those from which Weichselbaum isolated his meningococcus.

In this paper 111 cases were considered, and in 39 of them the infecting organism was isolated and cultivated; in most of the other cases the bacteriological diagnosis was based upon the finding of intra-cellular diplococci resembling the meningococcus by microscopic examination of the cerebro-spinal fluid, the nasal secretion, or aural discharge. In the remainder the diagnosis was based upon the clinical characteristics. Since this time, in America and Germany at least, the specificity of the so-called meningococci is now universally accepted.
THE MEDICAL PRESS. ORIGINAL COMMUNICATIONS. Sept. 2, 1903.

quite convinced that the meningococcus is not an attenuated form of the pneumococcus. He does not attempt to draw any clinical distinction between cases infected by the pneumococcus and those due to the meningococcus.

Netter's weighty opinion has carried with him the French and Italian schools of thought, it being generally held in those countries that the pneumococcus is the organism of epidemic cerebro-spinal meningitis.

It seems scarcely possible to settle this point until an epidemic of a disease whose symptoms resemble those of malignant fever occurs and is submitted to systematic bacteriological investigation. In 1899 Osler delivered the Cavendish Lecture on cerebro-spinal meningitis, he believed that the meningitis thus far was the specific organism of epidemic meningitis, but was fully aware of the possibility of infection by the pneumococcus.

In 1901 Thrusfield published some cases which confirmed Still's observation that posterior basic meningitis could be produced by an organism resembling the meningococcus; and a few months later Hunter and Nuthall recorded the bacteriology of the cases related in this paper.

In 1902 Hanshalter published a case of chronic hydrocephalus which, from microscopic examination, he concluded was the result of infection of the meninges by the pneumococcus.

In the present paper, basing the diagnosis upon the bacteriological examinations made by Hunter and recorded by him in the Lancet, an attempt has been made to analyse the conditions produced when this organism attacks the meninges. For this purpose, as has been explained, the cases selected are those only in which a complete bacteriological examination was possible.

Infection of the meninges by the diplococcus has thus been shown to produce symptoms suggesting identity with the disease described by Gillkrest, Sanderson, Weisburg, Councilman, and many others as epidemic cerebro-spinal fever, and also with the disease hitherto supposed to be limited to childhood, and described by Guersant, Rilliet and Barthez, Gee and Barlow, Carr, Still, Barlow, and Lees and Thrusfield, as simple meningitis, cervical opisthotonos, or posterior basic meningitis. Finally, it has been shown that infection by this organism may be one of the causes of chronic hydrocephalus.

Paris Clinical Lecture.

THE DIAGNOSIS OF A TUBERCULOUS ORIGIN IN ACUTE PLEURISY.

By Professor DIELAFOY.

Physician to the Paris Hospitals. (Concluded from page 214.)

Is this sero-diagnosis of tuberculosis applicable to the diagnosis of tuberculous pleurisy? This aspect of the question has been specially studied by M. Courmont, who found that it was possible to obtain a positive sero-reaction by mixing either blood serum or the pleural liquid of a pleural subject with the culture of Koch's bacillus (a mixture of 1 in 20, 1 in 10, 1 in 5).

The agglutinating power of the blood is not always equal to that of the pleural fluid; it may be more or less superior, and it may be negative. The positive sero-reaction is rarer when the pleurisy is associated with lesions of a serious nature; it is more frequent in cases of curable mild tuberculous pleurisy. Moreover, adds M. Courmont, the pleural sero-reaction may be absent at the commencement of the pleurisy and only become positive at the end of a certain time, generally towards the period of recovery. This author obtained with pleural liquid a positive sero-reaction in 23 cases out of 31 (74 per cent.); with blood serum 18 cases out of 22 (82 per cent.).

It was thought that Ehrlich's diazo-reaction could furnish useful information relating to the pathogenic diagnosis of tuberculous pleurisy (Clément). A positive reaction was observed in cases of tuberculous pleurisy (Georgiewski). The question has been studied by my interne, M. Loeper, and by M. Oppenheim. But this method of procedure furnishes untrustworthy results and will not be made use of to solve the problem before us.

A new means of investigation has just arisen; this is the cyto-diagnosis, or the diagnosis based on the quality and number of the cells present in the liquid of the pleural effusion. The cells are examined in the effusions of serous membranes in general. To the attack of the pathogenic agents, whatever they may be, certain cellular elements respond by an active and defensive reaction; but it is not always the same cells which react in the various provoking agents; there is, indeed, a kind of cellular selection.

Thus the polymuclear neutrophiles or microphages of M. Metchnikoff attack such microbes as the streptococcus or pneumococcus. The large mononuclears or microphages have a more powerful action; they readily digest the large cellular elements such as the red capsules and polyneurites. It was natural to suppose that such a cell had a more active control and reflected the nature of the provoking pathogenic agent. From this idea sprung the cyto-diagnosis. It was in 1900 that under the title of cyto-diagnosis, M. M. Wendel and M. Spurzheim published this splendid work of precise deductions and new discoveries. At that time, the ingenious and fruitful method which they had just brought to light was everywhere the order of the day, and it was made profitable use of it in the clinics of the Hôtel Dieu.

If, in a patient suffering from pleurisy, we wish to ascertain what the disease is, we examine the liquid of this pleurisy, we obtain aseptically, by means of a sterilised syringe, a few grammes of pleural fluid, which is then placed in a test tube; it is centrifuged and a clot sinks to the bottom of the tube. It is then decanted in such a manner that there remains a small quantity of liquid, which serves to form a turbid emulsion with the rubbed-down cellular clot. A single drop of this emulsion is placed on a glass slide, by means of a platinum wire, and we make a slide micrograph.

When preparations of the pleural fluid are examined under the microscope, we may see cellular elements of various aspects: red globules, polyneuronecocytes, big mononuclear cells, lymphocytes, endothelial cells, isolated or grouped in endothelial plates. But these elements do not exist indifferently in all pleurises the same pleurisy does not contain at the same time and quantity polynuclears, lymphocytes, mononuclears, endothelial cells; when we withdraw the red corpuscles, which exist in the majority of pleural effusions in a more or less large quantity, such a pleural fluid contains hardly anything but lymphocytes: the polyneurones and endothelial cells are either absent or in a very small minority; lastly, another pleural liquid may reveal hardly anything but endothelial cells and plates: the lymphocytes and polyneurones are either absent or in a very small minority. This is at times exclusive to such and such a cellular element in the liquid of the pleural effusion, constitutes the cellular formula of the liquid, and paves the way to the fundamental diagnosis of the pleurisy. From this point of view, MM. Wietz and Ravant admitted the existence of three varieties of pleurisy, each of which has a different cyto-diagnosis. One of these varieties concerns the liquids of patients suffering from an acute inflammation of the pleura, and the effusions due to neighbouring irritation or compression. Here we have no infectious agents, and therefore there is no cellular reaction, but only the mechanical phenomena of inflammation: it is a kind of congestive oedema. To use an old expression, we are more concerned, here, with a transudation than with an exudation—itis by transudation that a liquid drags the endothelial cells of the serum.
into the pleural liquid. Again, have these so-called mechanical pleural effusions a cellular formula which is peculiar to them? Usually the liquid contains neither lymphocytes nor mononuclears (at any rate during the first period). It contains, almost exclusively, the big endothelial cells resulting on the desquamation of the serum.

These more or less large and numerous endothelial pleural cells characterise the so-called mechanical pleurises. MM. Widal and Rovart observed them in twelve cases of pleurisy of this sort; the post-mortem of three patients attacked by these pleurises, and also the negative result of the intra-peritoneal inoculation of these big guinea-pigs with the liquid of seven other pleurises of the same nature, prove that in similar circumstances it cannot be put down to tuberculosis. Not only are these endothelial collections characteristic of mechanical pleurises, but their presence in a pleural liquid permits us to exclude the hypothesis of pleural tuberculosis; they are not found in the liquid of tuberculous pleurises, without because the pleural tuberculosis neo-membrane hinder desquamation in threads of the endothelial of the membrane. We noticed this in our hospital: the liquid of our tuberculous pleurises, which was very rich in lymphocytes, did not contain any endothelial pleural cells.

This knowledge may be very useful in clinics, as I will now show you. A patient suffering from pleurisy who spits blood is naturally suspected to have tuberculosis. Some haemoptysis is not uncommon in a case suffering from cardiac disease. Should there occur a pleural effusion in the cardiac subject, therefore, the cyto-diagnosis will show that the liquid, which contains endothelial plates, is that of a mechanical effusion and not of tuberculous pleurisy, which is very different in respect of prognosis.

I had occasion, quite recently, in regard to two patients in the St. Christopher Ward, to discuss haemoptysis in pulmonary form from idiopathic disease. This disease predisposed to hemorrhage and the patient may bleed from the bronchi just as well as from the nose. I told you that this haemoptysis could appear at an epoch when the nephritis had not yet been masked by the major phenomena. If a pleural effusion were to occur in such a patient whom you knew to have had haemoptysis, tuberculous pleurisy would be the first idea that comes to you. Practice cyto-diagnosis, when you will find the endothelial pleural cells, and you are enlightened as to the nature of the pleurisy; it is a mechanical effusion, and has nothing in common with the tuberculosis pleurisy of a case suffering from Bright's disease. I mentioned to you that the mechanical pleurises containing endothelial plates do not usually contain lymphocytes; this is true during the first phase of the pleurisy; but, later on, the lymphocytes may appear, in the presence of the plates sufficient to constitute the diagnosis.

In the second variety of pleurisy, the pleural liquid has quite a different formula, and concerns acute infective pleurisy; the pathogenic agents, the streptococcus, pneumococcus, the typhoid bacillus, &c., after provoking the active defensive cellular reactions, can no longer exist in the liquid, but the results of this struggle, the phagocytes, the phagocytes and the lymphocytes, are met with in abundance. There also exist big mononuclear cells, which sometimes are big leucocytes, and at other times are derived from the serum membrane, and amongst the few endothelial cells isolated or absolutely normal. Summing up, the polyvalent and mononuclear elements characterise infective acute pleurisy; the lymphocytes, when there are any, are of secondary importance, and it is exceptional.

In connection with these pleurises MM. Widal and Rovant give the following: "In three out of eight typhoid pleurises the relative abundance of the large polyvalent leucocytes characterised the formula of the effusion. In the cases of streptococcic serofibrinous pleurisy there were only polynuclear leucocytes and deprived nuclei. The liquid of pneumococcal pleurisy is characterized by the presence of red corpuscles and a few lymphocytes, but especially by the abundance of polynuclears and by the existence of a more or less large number of big mononuclear cells, of which a few true macrophages envelop the polynuclear cells in their protoplasm. These elements are sometimes large, mononuclear leucocytes, at other times endothelial cells derived from the serous membrane.

In a patient in St. Christopher Ward, attacked by pleurisy, which became foul a few days later, there were only polynuclear leucocytes in the effusion; the aerobic and anaerobic cultures of the liquid revealed variable microscopic contents.

Let us pass on to the pleurisy of the third variety of pleurisy, the most important of all, that which corresponds to the most frankly acute pleurisy a frigore. On microscopical examination of the preparations made with this fluid, it will be seen that its cellular formula is characterised by the almost exclusive presence of very conglutent lymphocytes and mixed, in comparatively large numbers, with red corpuscles. Sometimes, at the same time as the lymphocytes, which, at first sight, appear to be large elements are sometimes large, mononuclear elements; there may be observed here and there a uninuclear element. Polynuclears when they do exist are not numerous; they are perhaps the result of a secondary endothelial pleurisy.

As to the third variety, the pleurisy frigore, it would be of very rare occurrence, since in seventeen cases MM. Widal and Rovant failed to discover them.

The following observation, which was given to me by M. Widal, in March, is instructive. A young man, aged 21, was attacked on April 19th last, whilst travelling, with symptoms of a pleurisy a frigore; repeated trembling, a pain in the right side, and mental confusion. On April 27th, on the ninth day of the malady, he presented all the symptoms of a classic right pleurisy. On April 29th, thoracostasis was done and two litres of yellow liquid were withdrawn. This liquid had a typical pleurisy formula. On the following day, the general condition was good, but the temperature was high, 39°-40° C. On May 2nd, four days after the puncture, at 5 a.m., the patient sat up in bed, became dyspneic, and died in a few moments. At the post-mortem the left lung was found to be surrounded by adhesions, the left branch of the pulmonary artery was occluded by a blood-clot, no tubercles; the right lung was slightly oedematous; it did not contain any tubercle; the pleura on that side contained about 1,500 grammes of sero-fibrinous fluid, the two layers were adherent at the apex, behind and to the right of the pulmonary pleurisy.; not a case of pleurisy of the antero-lateral region of the great pleural cavity. The most minute examination of the two pleurisy with the naked eye failed to reveal any tuberculous granulations. A large blood-clot extended from the right ventricle to the left branch of the pulmonary artery. Perhaps, you have the reason for the sudden death. Kidneys were normal. Numerous histological sections of the pleura enabled us, however, to everywhere note tuberculous tissue; a considerable number of giant-cells are seen in the fibrous layer of the inflamed membrane. This interesting observation embodies the whole question. Here we have a frankly acute pleurisy which would formerly be diagnosed as idiopathic pleurisy, while in reality it was tuberculous (primary pleuro-tuberculosis). On cytoscopic examination of the liquid being made we only find lymphocytes and red corpuscles; the pleurisy is therefore diagnosed as tuberculous pleurisy. Later on, the histological examination of the pleura, and the tuberculosis which had developed in guinea-pigs inoculated with the pleural liquid, confirms the results of the cytoscope. Not a case of tuberculous pleurisy; it has been applied to effusions of other serous membranes, the peritoneum, pericardium, cerebro-spinal liquid, and in a large number of cases it established the tuberculous nature of the complaint.

The result of this long discussion is, that we are in possession of numerous methods of discovering the tuberculous nature of an acute pleurisy; inoculation to the pleural serum of guinea-pigs, the tuberculin, the culture of the liquid in glycerinated gelose
blood, sero-diagnosis, cyto-diagnosis, are all methods which have been successfully employed and recommended. Of them all, the method I prefer is cyto-diagnosis, because it is simple, easy, gives prompt results and is absolutely innocuous. The future will show whether it also has any drawbacks.

To sum up, in all patients suffering from pleurisy you should have recourse to cyto-diagnosis. If you can, in the first instance, send the liquid to a laboratory. For this purpose, place a few cubic centimetres of the pleural liquid you have just withdrawn in a small test tube. A coagulum usually forms which comprises all the constituents of the liquid. The histological examination is about to be made it is only necessary to shake it up, taking care to decant the fibrinous material and then centrifugating until a slight deposit has formed at the bottom of the tube.

Any liquid of acute pleurisy (even though the patient is vigorous and free from obvious taint) in which you observe an abundance of lymphocytes with red corpuscles, and the absence of endothelial plates, is the liquid of a benign pleurisy. The cytological examination of the pleural effusion is just as necessary as the bacteriological examination of the expectorations in cases of doubtful pulmonary tuberculosis. In all cases of pleurisy cyto-diagnosis is necessary. A cytological examination of a pleursy in which cyto-diagnosis is not practised will be henceforth an incomplete examination.

However sure you may be of your clinical diagnosis, it is not sufficient; you may be taken by surprise. A certain pleurisy which you may have considered to be tuberculous because it occurred in connection with obvious pulmonary tuberculosis may not be tuberculous; although you may have thought it to be merely influenzal because it occurs during the course of convalescence from that disease may turn out to be tuberculous pleurisy which has developed consequent upon the disease. Certain serous-fibrous pleurisies, which we should be inclined to ascribe solely to traumatism, are in reality tuberculous pleurisies, the traumatism having favoured the appearance of the tuberculous bacillus.

You will note that in this discussion I have duly dealt with acute tuberculous pleurisy; it is especially to this variety that the method of investigation described above applies. It may, however, apply to the tuberculous pleurisy of several months' standing.

In the case of a man in St. Christopher Ward who is suffering from a pleurisy which has been diagnosed by several physicians since it is an aspiratory puncture giving rise to a litre of yellow liquid; the presence of lymphocytes and red corpuscles revealed the tuberculous nature of this pleurisy, and sero-diagnosis gave a similar result.

But the formula may be quite different if it be a case of tuberculous pleurisy of old standing, and especially of tuberculous hydropneumothorax, or of pleurisy developed in connection with extensive tuberculous lesions of the lung. Under similar circumstances it is not lymphocytosis which predominates, but old deformed polynuclear cells, with segmented nuclei; sometimes also elements made up of vesiculated protoplasm and exudates; it may appear to be due to the exudate from the endothelium. In this category of pleurisy we must look to clinical observation to form the diagnosis. In doubtful cases, we might have recourse to cultures, inoculations and sero-diagnosis, but experience has shown that sero-diagnosis and inoculations give less exact results when the lesions are of ancient date than when they are recent.

Can we, then, decide whether a frankly acute sero-fibrous pleurisy is or is not tuberculous? I maintain that we can, and it is, I think, cyto-diagnosis which furnishes the most trustworthy information, because it is not subject to the drawback of the other methods. In the first place, it is free from the comparison of pleurisy answering to the description of the so-called frankly pleurisy a frigore are in reality cases of tuberculous pleurisy, cyto-diagnosis branding them and pleural lymphocytosis revealing their origin.

We shall then note that there are infective agents capable of causing frank acute pleurisy which have nothing to do with tuberculosis. This group of acute pleurisies has no connection with tuberculosis; bacteriology has classed these pleurisies according to their pathogenic agents; cyto-diagnosis classifies them in the same cellular formula; they are pleurisies with polynuclear and mononuclear cells.

Let us now discuss another aspect of the question. If so-called acute pleurisy be tuberculous, how can we explain its frequent enough disappearance without leaving the slightest trace? This is not, I think, the chief argument raised against the suggestion. Our theory must be that the probability of pleurisy being recovered from does not necessarily imply that it was not tuberculous. Tuberculous pleurisy is sometimes due to localised tuberculosi of the pleura (primary pleuro-tuberculosis); the pleura only is attacked, the lung being intact and the rest of the organism healthy. The serous membrane being well armed for defence, it is not surprising that the attack of pleurisy should subside without the infection being transmitted elsewhere. Moreover, this curiosity is not peculiar to tuberculosis of the pleura, for other serous membranes possess the same defensive property.

Tuberculosi of the articular synovial membranes, from simple arthritis to chronic synovial pleurisy is necessary to be frequently recovered from, and the same remark applies to tuberculosi of the pericardium. We no longer enumerate the instances of recovery from peritoneal tuberculosis, especially in the cases of ascites, formerly grouped under the title of essential or a frigore ascites, are unquestionably cases of attenuated readily curable tuberculous peritonitis. Some yield to medical treatment without surgical intervention; others, after mere puncture with or without consecutive injections; others, again, after simple laparotomy.

This tendency to recovery is also observed in simultaneous tuberculosi of the pleura and peritoneum (pleuro-peritoneal tuberculosis). It is evident, then, that tuberculous pleurisy is susceptible of cure; indeed, it is sometimes remarkably benign. M. Péron, who has studied this question from an anatomical and experimental point of view, arrived at the same conclusion: "In tuberculosis sero-fibrous pleurisy, which presents the clinical aspect of a so-called frank acute tuberculosis, the bacillary infection is at its minimum, while the reactions of the organism are well marked."

The curability of tuberculous pleurisy suggests to me certain reflections. From that now distant date when I first introduced the operation of aspirating fluids, I have practised, or had practised, in more than one of my clinics, a very large number of thoracenteses by aspiration; for some years my house physicians have published a detailed account of our cases of pleurisy treated by this method. Thanks to these documents I am enabled to affirm that all pleural tuberculous effusions, whether the pleurisy was primary or secondary, are amenable to treatment by aspiration. I will go even further and assert that with carefully prepared a cure is almost the rule, especially in primary tuberculous pleurisy.

But when we speak of the cure of tuberculous pleurisy we are not really thinking exclusively of the pleura. The question is rather: do we ask ourselves whether the pleurisy is cured will at some later period attack the lungs? Is the patient predisposed to tuberculosis? This is the question in a nutshell, and it is somewhat difficult to pathologists and experimentalists to answer. You will have deduced from what has been said that a definitive cure occurs, especially in cases of primary pleuro-tuberculosis of purely pleural localisation, the lung remaining intact. But how are you to prove that the lung is not invaded in one or other latent condition without revealing it by the slightest symptom, and this unknown focus may at any moment give rise to a tuberculous "explosion." This fact
explains how it is that we meet with rapidly mortal cases of military pulmonary tuberculosis which appear to be of primary origin although in reality they are consecutive (the post-mortem proves it) to a small tuberculous lesion which, until then, had been latent.

The same reasoning holds good for tuberculous pleurisy. A healthy individual is attacked by frank acute pleurisy; cyto-diagnosis (pleural lymphocytosis) shows his pleurisy to be tuberculous. Everything pleads in favor of a primary and localised pleural lesion, but, at most examination fails to reveal the slightest pulmonary lesion. Yet this primary pleuro-tuberculosis may very possibly be consecutive to a minute primary pulmonary focus, which has infected the pleura and which has up till then run a latent course.

All that precedes tends to prove that the genuine primary pleuro-tuberculosis not associated with any pre-existing lesion of the lung, as well as the pleuro-tuberculosis consecutive thereto, are latent foci of infection, and may both assume the appearances of so-called frank a frigore pleurisy. In many cases it is impossible clinically to distinguish them, since cyto-diagnosis places them under the same cellular formula.

But these two varieties of tuberculous pleurisy are not comparable in regard to prognosis, for the one is by no means so grave as the other. Primary tuberculosis pleurisy, it is possible for the pleural lesion to heal without the infection becoming generalised. But if the lung is already involved, however small the lesion, the outlook for it is fatal, and when this happens for we then have to deal with a double tuberculosis, that of the lung and that of the pleura. The prognosis in acute tuberculous pleurisy is, as may be seen, somewhat uncertain.

Although the outlook in acute pleuro-tuberculosis is not unfavourable in its initial phase, do not repose too great a confidence in its relative benignity. With regard to this, acute pleuro-tuberculosis is generally a year or more associated with copious effusion. This effusion is a method of defence; perhaps the lung, pressed back and compressed by the effusion, has less tendency to be invaded by pleural tuberculosis. I cannot affirm this for certain. If this hypothesis be true, common sense would lead us to deprecate too early recourse to thoracentesis. But, on the other hand, we know what grave results follow the presence of a large quantity of liquid in the pleura. Sudden death may result from it and many are the theories invoked to explain its occurrence.

In a communication to the Academy of Medicine on the treatment of pleurey, a patient in the midst of this appalling accident: I easily collected forty examples of it, and yet we do not know the whole of these catastrophes, since the majority of them are not published. In analysing these observations we find that they are singularly alike in their details—at each moment one sees that the patient who died suddenly was attacked by an effusion followed by merely insignificant dyspnoea, so insignificant, in fact, that, in many cases, thoracentesis was not resorted to.

Do not forget that dyspnœa is an untrustworthy and even deceitful guide with regard to the necessity for thoracentesis. It is solely the amount of the effusion that should guide us. No sudden death due to an effusion of less than 1,500 grammes (or, at any rate, but in very rare exceptions), whilst the patient may succumb suddenly with a more copious effusion. It is therefore necessary for you to know how to ascertain the approximate quantity of the effusion. This is easy owing to the information furnished by percussion, auscultation, and by the displacement of the adjacent organs, notably of the heart in a left-sided pleurisy.

Radiographic exploration furnishes us with far more precise information.

Another question of not less importance. You are aware that in a case of acute tuberculous pleurisy the pleural fluid moves rapidly and in great quantities after thoracentesis. I noted that this rapid and persistent reproduction of the liquid was much less frequent in acute infectious non-tuberculous pleurisy. On several occasions in patients suffering from acute tuberculous pleurisy, I have had occasion to withdraw in two or three sittings two or three litres of serofibrinous liquid. The effusion was for the moment checked, the symptoms of effusion were replaced by friction, hiccoughs, and the patient thought he was cured. But, without any rise of temperature, pyonœa, or palpation of the pleural liquid insidiously reformed to such a degree that in a few days it reached a litre and a half, two litres and even more.

Beware, therefore, of acute tuberculous pleurisy; it is a malady replete with surprises for the unwise practitioner. Its course is insidious, and the irregularity of its appearance is not the least interesting feature from your point of view. You must retain the quantity of effused liquid, and practise thoracentesis if it appears to you to be required. Continue to watch your patient, even if the acute stage seems to have come to an end; examine him every day and do not forget that the effusion you have evacuated may recur rapidly and pave the way to sudden death, unless, warned by experience, you have warded off this contingency.

So much for the active phase of acute tuberculous pleurisy. The treatment, however, does not stop there. The pleuritic subject is convalescent, but beneath the appearances of health the tuberculous lesion of the pleura persists. The person convalescing from acute tuberculous pleurisy ought to remain under treatment for a long time, even when he considers himself cured. The tuberculous infection dogs his footsteps. It is necessary for you to know that you must guard against this. The patient must avoid any cause of overwork and loss of strength. His nourishment must be substantial and varied; you must choose those aliments and drinks which excite the appetite, especially for those who have to reside in the preference high altitudes, and the patient must accustom himself to an open-air life. All exercises are permissible, on condition that he never pursues them to fatigue.

With regard to the tonic and strengthening treatments, you will prescribe cod-liver oil, in increasing doses, from 40 to 200 grammes per day, if it is well tolerated; for people who cannot take cod-liver oil, advise fatty aliments, cream, bread and butter. Certain hars-d'ambre, oysters, caviare, sardines in oil, fish, and smoked meat ought to form part of their alimentation. You may have recourse to raw meat and meat juices, which have proved very useful in the treatment of tuberculosis. The good effects of this régime do not depend on the phenomenon of super-alimentation pure and simple, but on the particular anti-tuberculous quality of the food.

Give each meal, in a small glass of wine or water, 30 drops of a preparation composed of equal parts of tinctures of kola, cocoa, and bark. Give injections of cacodylate of soda in doses of 05 centigrammes every fifteen days for several months. The efficacy of this treatment has been proved. Induce your patient to attend to himself carefully and avoid all exposure.

The Out-Patient Departments.

TOTTENHAM HOSPITAL.

CASES FROM THE DERMATOLOGICAL CLINIC, UNDER THE CARE OF G. NORMAN MEACHEN, M.D., M.R.C.P. Lond. and Edin.

I. Lichen Planus Hyper trophyicus.—A married woman, aged 68, came for an eruption which had troubled her for two years, it never having completely disappeared during that period. The itching was at times intolerable. She had not had any previous illnesses, nor had she suffered from any mental shock.

On inspection, there was a copious, dark red eruption present upon the legs, thighs, and back, consisting of small papules and pustules. Those upon the thighs and back were flat-topped and somewhat shiny. There were several irregular, warty patches of a brownish-red colour upon the extensor surfaces of the legs. There was no rash on the shoulders or wrists. The mucous
membrane of the mouth was not affected. She complained of feeling "out of sorts," and the bowels were constipated.

Dr. Meachen remarked that it might be possible for a superficial observer to mistake the condition upon the legs for psoriasis, but that the patches had neither the colour, the scaliness, nor the distribution characteristic of that disease. Moreover, if the inner side of the knees were carefully examined in this case, several of the shiny, striated, flat-topped papules, pathognomonic of lichen planus, could be seen, and these were never found in psoriasis.

Pruritus, also, though occasionally complained of in the latter affection, was usually far more intense in lichen planus. The warty irregularity of some of the patches might, perhaps, suggest to some the verrucose variety of lupus, but such a diagnosis was rendered quite impossible by the length of history, and the absence of lupus nodules in or near the patches.

The patient was ordered a creolin bath, to be taken every night, and an ointment of creolin (5 per cent. zinc oxide, and lead acetate. She was given an apertive mixture of iron three times a day.

11. Purpura Scrotulica.—The patient, a pale young woman, was a "waitress, came for ‘spots on the legs,’" which she had noticed for three weeks, and which were preceded by aching pains.

On inspection, there were numerous purpuric patches, some well-defined, of varying sizes, situated upon both legs, flexor and extensor surfaces alike, and a few smaller ones upon the thighs and forearms. Two or three fuscoid bullae, containing hemorrhagic serum, were seen above both ankles, and the surrounding parts were tender to the touch. The patient's breath was very foul, and on examining the mouth blood was seen to be freely oozing from a hollow upper molar tooth and also from the adjacent part of the gums, which were slightly enlarged, and especially behind the upper central incisors. Mastication was painful. There were no hemorrhages from other mucous membranes, except that the catamenia were too profuse. There was no history of hematuria.

On further inquiry from the patient, the fact was elicited that for the past eight months, during which she had been a resident waitress in a City hotel, she had subsisted upon a diet conspicuous by its lack of fresh meat and vegetables. The meat was stewed up again and again, while the potatoes and greens were "mixed together and fried in fat." She lived chiefly upon tea, ale, and sometimes bread and butter.

In presenting the rarity of scurvy in modern, well-fed communities on land, Dr. Meachen said that such could only be the diagnosis in this case, though, at first sight, a severe form of purpura simplex in an anemic subject might appear from the report itself. Against this the following points may be urged: (1) the ill-defined "shading-off" character of the purpuric spots; (2) their almost entire localization to the lower extremities, especially to the region about the ankles; (3) the tenderness of the skin and tendency to the formation of bullae; and (4) the clear history of the deprivation of fresh food.

The necessity for an alteration in the diet was fully explained to the patient, who was instructed to take fresh lemon-juice, grapes, and, above all, fresh milk, and soft, easily masticated food. She was given an astringent antiseptic gargle of tannic acid, myrrh, and boric acid, and the mouth, after removing her inability to obtain the proper treatment at home, she was ultimately admitted to the hospital, where she made satisfactory progress.

BRITISH SANATORIA FOR CONSUMPTION.—X.

[BY OUR OWN MEDICAL COMMISSIONER.]

THE WESTMORLAND CONSUMPTION SANATORIUM.

Many excellent sanatoria now exist in Great Britain and Ireland where the well-to-do consumptive may obtain the best and enjoy the most suitable conditions making for recovery; but for those of meagre means the available accommodation is deplorably inadequate. For the benefit of the individual it is most desirable that efficient treatment be provided during the initial stage of the disease, but for the safety of the State and the speedy stamping out of pulmonary tuberculosis it is essential that the individual be taken in hand, if the inner side of the two wards, and two in each of the four permanently used shelters, besides apartments for the resident medical officer, the matron, three nurses, and four maids. That we consider that by the judicious expenditure of comparatively small sum the present accommodation might be considerably improved and
much extended. It may be hoped local spirit will be stirred to maintain in a high state of efficiency what is a credit and distinction to the County of Westmorland.

Of the twenty-four beds at present available, twenty-one have been acquired by various councils and other public bodies subscribing £60 a year, and to which only residents in the county are nominated. Such patients pay £15 a week. The average cost of maintenance is about £65 a week per patient. Such beds as are not filled by Westmorland patients are available for suitable cases from districts outside the county at a uniform charge of two guineas a week.

The average length of stay of cases in the early stage of the disease is twelve weeks, moderately advanced cases eighteen weeks, and of cases in the quite advanced stage twenty-four weeks. It seems a mistake to admit hopeless cases in association with those who may be relatively “cured,” and the Committee recognising this have, we understand, taken action with a view to devising some practical plan for dealing with persons in the county suffering from consumption in too advanced a stage to experience permanent benefit in the sanatorium.

The results hitherto obtained are certainly encouraging. The majority of the cases admitted in an early stage, and enjoying the benefits of a three months’ residence in the sanatorium, are able to return to some years of useful work.

The sanatorium is well placed, but in some respects the site is hardly ideal, and greater protection from winds would be an advantage. The ground connected with the institution is limited, but the country in the immediate neighbourhood offers plentiful facilities for exercise.

The shelters are all of simple construction, and evidently strict economy has been studied in their preparation, but they are effectual and patients seem to do well in them.

The matron is a trained nurse, and the resident medical officer and some of the nurses, we understand, have been the subjects of pulmonary tuberculosis and are thus specially well equipped to meet the particular needs of those under their care.

Treatment is conducted in strict accordance with modern hygienic methods. Except under exceptional circumstances, the rooms are not heated. The dietary is simple, good, varied, and abundant.

It would be well if greater facilities could be provided for the scientific investigation of cases, and we certainly think it would be well if, instead of the auxiliary temperature being registered, charts were kept according to the oral records.

The details required by the medical certificate, which has to be submitted before a patient is admitted, appear to be too meagre to afford much directing value in the selection of cases.

The third annual report, issued at the commencement of the present year, contains much of considerable interest regarding the condition of the cases on admission and the results of treatment. The statement of accounts shows the sanatorium is conducted on lines directed by experience, discretion, and strict economy.

Westmorland may well be proud of its effort to provide for the consumptive poor, for it has indicated a path which other counties may well follow.

MANAGEMENT OF THE WOUNDED IN NAVAL WARFARE.—I.

Some useful information as to wounds and the care of the wounded in a naval war may be gleaned from a work published in Japan in the English language, on "The Surgical and Medical History of the Naval War between Japan and China during 1894-95." Much has been written about the wounds received in wars on land; indeed, the "Medical and Surgical History of the American Civil War" is full of interest and information. Of naval warfare we possess no medical history. The lessons of Trafalgar and Lissa, and the war between Chili
and Peru, have been lost to us, and there has been no previous experience of the treatment of the wounded on ships since the modern revolution in naval warfare.

**Surgery in the Ship.**

The surgery of a ship ought to be conveniently placed for collecting the wounded from the various parts of the ship, and also in places least liable to be disturbed or destroyed. In the men-of-war of former days, as in the time of Nelson, there was a wide hatch extending vertically from the upper deck to the bottom, and below the water-line, which was admirably adapted, being in the centre of the ship, for a spacious surgery. Nowadays this part is occupied by the engine-room, coal bunks, &c., leaving no room for the wounded. The chief experience in every ship, then, is that surgery must be placed at the fore and aft of the ship, and consequently two are necessary, for it would be inconvenient to convey the wounded from one end of the ship to the other, especially so when the water-tight doors were closed, necessitating a very roundabout communication between the fore and aft of the ship. But if both were not all the ships the same, it was no room for surgery at the fore or aft below the water-line, therefore places like the lower deck were chosen, which is above the water-line, and not quite free from the intrusion of hostile shells; so it was the general scheme that two surgeries, one at each end, should be established. But some ships, lacking room, had to be content with only one surgery. The Hysie is an instance of this kind, and in the surgery, which was established in the wardroom at the rear of the lower deck, was hit by an enormous shell, which killed all the surgeons and others who happened to be there, or at least inflicted serious wounds, and also destroyed nearly the whole of the surgical instruments, &c. In another vessel two surgeries were established, one on the upper deck of the fore part of the ship, and the other at the end of the lower deck; both were destroyed by shells, and the explosion of ammunition; and at this time the chief surgeon of the fleet were seriously injured, and some of the wounded persons then receiving treatment were killed. This caused also a great loss of surgical instruments.

We see, therefore, that any part that is above the water-line is not free from the danger of being struck by shells, and is, of course, unfitted for a surgery; but in the absence of room below the line, there is no alternative but to be content with what is obtainable. In order, therefore, to facilitate the conveyance of the wounded and avoid a wholesale catastrophe like that experienced on the Hysie, it is prudent to have two surgeries. But this division has also its disadvantage, for dividing the surgeons, nurses, and surgical implements that are anyhow limited in number and quantity in every ship, it affords much inconvenience in treating many wounded men at the same time. In battles, sometimes fifty or sixty are wounded at a time and in one place. Supposing this should occur in the fore part of a ship, the wounded will naturally be brought to the surgery in the hinder part of the ship, which is suddenly crowded and short-handed, although only urgent measures of relief are taken during the fight, yet even then it is impossible to pay proper attention to all the wounded. At the same time, the medical attendants in the other surgery may have nothing to do, and yet they are not able to help each other, which is a hindrance to successful treatment. The disturbed fact that many wounds afterwards suppured was probably greatly due to the impossibility of giving anything more than temporary relief at the first. This separating of the surgeries may be unavoidable, but it is necessarily attended with great drawbacks. If a single surgery could be placed in the middle of the ship where persons wounded at various parts could conveniently be collected, and at a place below the water-line least exposed to the danger from shells, it might then be called a suitable one.

**Conveyance of the Wounded.**

Apparatus for the conveyance of the wounded can no more be uniform in size and construction than ships can. Various kinds of bed have been provided for use on board, and one like an easy-chair, the hammock, Macdonald's or Gphon's stretchers, &c., and the men had been drilled beforehand in their use. But during the actual engagement it was found that stretchers of all kinds were cumbersome and troublesome, and of very little use for the speedy conveyance of a large number of wounded to the surgeries during the noise and confusion of the battle. Hands therefore were posted on every ship, were on board the ships, and the stretchers were laid aside. Conveyance by hands alone is prompt and convenient, even if there be many wounded persons at one time, for every man who is uninjured can generally be useful for carrying wounded men; and so during the actual battle the Japanese were obliged to resort to this method. But even then a seriously wounded requires the assistance of four or more men to get him up or down stairs, and there is always a great deal of confusion in the removal; also, in the conveyance of patients who have sustained fracture or extensive burns, this method certainly aggravates the injury, and from this point of view carrying on stretchers is by far the better.

**Treatment of the Wounded.**

At first only urgent and temporary measures of relief were taken, such as to wash the insides of the wounds, to disinfect the surrounding skin, to extract foreign bodies when they could be easily seen and removed, to staunch haemorrhage, by compression or sponging, and in case of a fracture to apply splints. This is inevitable in a battle; but the individual and the patient to the patients. When the battle was over, proper treatment was accorded in the order of the urgency of the respective wounds. At the time of the second treatment the wounds were again disinfected within and around, any foreign body that was recognised by exploration was removed, splints that were found not to have been properly applied were replaced, and so forth. The principal antiseptic used in ships for irrigation of wounds and other similar purposes was a solution of carbolic acid, 2 1/2 to 3 per cent., sometimes supplemented by a sprinkling of iodiform. To wounds in the eyes, chest, and abdomen a solution of boracic acid was chiefly used. For dressing materials, corrosive sublimate gauze, carbolic acid gauze, or absorbent cotton wool were employed, with linseed oil paper and bandage applied over them. The splints used were all made of wood. For gypsum bandage, which is very inconvenient for use on ships during action, wooden splints proved an efficacious substitute. In spite of the great attention paid on each ship to the washing of wounds with antiseptic solution, the process was not thorough enough to prevent suppuration, and the surgeon only supposed and therefore plain that stronger measures should be taken with shell wounds. Shell wounds are extremely disposed to suppuration, and the conditions on board ships during action were likely to soil wounds; and, besides, the surgeries were all in unsuitable locations. With shell wounds sustained in parts covered with clothes, a soiled piece of cloth is very frequently found remaining within, and there were not a few cases in which these foreign substances were taken out in the hospital, to which the patients were admitted many days after injury. On account of the loss of vital function, the wound surface cannot resist even a few micro-organisms, if once admitted. The surrounding tissues should therefore be strictly disinfected, care
being taken at the same time that the disinfection should cover a larger area than that which is protected by dressing materials. The inside of the wound cannot be expected to be perfectly cleansed during the confusion of fighting, so if the quantity required be not as large as to cause poisoning, a solid antiseptic like iodine may conveniently be sprinkled into the wound.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, August 30th, 1903.

DANGER OF HAIR DYES.

Dr. Lamargue has drawn attention to the danger of capillary tinctures and more especially of the vegetable kind. These products, composed from paraphenylenediamine and oxygen water, largely employed on account of the fine colour they produced, were exceedingly toxic, and caused accidents not only to the skin, but to the mucous membranes and the internal organs, such as itching and swelling of the eyelids, injection of the conjunctiva, itching of the nose, frequent sneezing, sensation of dryness and constriction in the throat, albuminuria.

IMPETIGO.

Prof. Jacobsen recommends for this troublesome malady the painting, once, of the surface with a solution of nitrate of silver (1—10). When the caustic touches the epidermis the patient experiences a sharp burning sensation for a few minutes. The following day the lesion is dry and black, naturally: the aspect of the surface has completely changed. While before the application it was swollen, uneven, and divided in many places by ulceration and crevasses, it is now more uniform, the congestion has disappeared, and a tendency to heal has begun.

The improvement continues the following days, and in a short time the black colour disappears and underneath is found an epidermis of neo-formation, smooth and without the slightest infraction. This method of treating impetigo insures the complete cure of an affection which, although not very grave in itself, yet could have a bad influence on the development of the children.

ODIUM ALBICANS.

The usual remedy for aphthous stomatitis is a mixture of borate of soda and glycine or honey, but M. Merletti considers that swabbing out rapidly the mouth with oxygenated water followed immediately by a similar operation with a 5 per cent. solution of borax, gives better results under the influence of the combined treatment. An abundant froth is produced by the decomposition of the oxygenated water. The oxygen destroys the parasite and exercises a salutary influence on the inflamed mucous membrane. According to the author, this mixed treatment repeated only three times in the twenty-four hours cures rapidly the gravel forms of confluent aphthas.

INGROWING NAIL.

According to Dr. Blanc, the most rapid treatment of lateral onyxis is that of applications of finely powdered nitrate of lead. Eight days are generally sufficient to effect a cure, and the treatment has not only the advantage of being painless, cheap, and easily applied by any intelligent person, but also of allowing the patient to continue his occupation. Before the first application a prolonged foot-bath should be taken, then by the aid of a flat spatula a thin layer of cotton is slipped between the nail and the funguid growth to protect the healthy part of the nail. After powdering the parts, a wet compress is applied. The dressing should be renewed every day.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, August 30th, 1903.

AT the German Surgical Congress, Hr. Sonnenburg read a paper on the SIGNIFICANCE OF LEUCOCYTOSIS IN PERITONITIS.

In his examination of the blood changes in peritonitis he had recognised that the increase or diminution in the number of white blood corpuscles was an aid in prognosis. The leucocytosis test was a complement of the temperature test. Not enough use was made of the test at present.

Hr. Federmann had, during the last few months, made the test under Sonnenburg's guidance in 150 cases of acute disease. All the cases were operated on, and the diagnosis was confirmed in all. The examinations had the object of leading to a determination as to whether an operation should be performed at once, or whether it should be done later under more favourable conditions. The participation of the peritoneum was of importance. Twenty-five were cases of simple appendicitis, with catarrhal inflammation, the sero-fibrous form. Here the diagnosis was easy; for the first few days the leucocytosis was from 20,000 to 30,000, which in the course of four or five days returned to the normal. In the purulent form, the circumscribed and the advancing must be distinguished. Of the first class 70 cases were examined, they were cases of primary suppuration, here also for the first few days there was a leucocytosis of 20,000 to 30,000, which in the first five days fell to 15,000 to 18,000. In the advancing form there was increase and a fall when the advance came to a standstill. Thus the leucocytosis gave a picture of the anatomical conditions. The gangrenous form had a typical leucocytosis curve—steep ascendency, continuous and a descending limit. The graver the case the quicker fell the leucocytosis, the higher the curve rose the better the prognosis as regarded operation. The proper estimation of the value of leucocytosis could only be arrived at by consideration of the whole assemblage of symptoms, pulse, temperature and local condition.

Hr. Körte, Berlin, inclined more than formerly to early operations. This might be partly due to the fact that of late he had not more than seven cases, but the change was based on the observation that a number of cases that for external reasons were not operated on took on a grave and unfortunate course. In early operations in quite acute cases he had many times seen pus in the abdominal cavity within 12 to 14 hours after the commencement of the illness; of these early operated on cases not one had died. But many of the acute cases were cured by waiting also. In general a determination before the third day was uncertain. He operated early in every grave case.

Hr. Sprengel, Brunswick, pointed out that 1,000 people died every day from peritonitis in the German empire. It was their duty therefore with all their might to keep down this dreadful mortality. His colleague, the physician, now sent all cases of appendicitis into the surgical wards where they were operated on at once. In this way he had carried out 36 early operations with only one death from later septic pericarditis. The average mortality of each operation was at most 3 per cent. Perforation of the appendix was not different from perforation of other portions of the intestines, and must be treated in the same way. If the bowel was still collapsed the prognosis was favourable, if the bowel was distended fatal intestinal paralysis was to be dreaded. If no distinct improvement had taken
place in the first 24 hours an operation should be performed. The possibility of a rupture forming should not deter from operation, we must only try to avoid one. The counting of the blood corpuscles was only a way made use of by the physician of keeping the surgeon from operating. It left one in the lurch in bad cases and did no good.

Hr. Sonnenburg was of an opposite view as regarded the counting of the leucocytes. Since 1890 he had treated 671 cases of perityphlitis, of which 573 were operated on and 104 treated expectantly. His earlier view to operate on every case at once, he had modified from his later experiences in so far that where the symptoms were not pressing, he now waited for twice 24 hours.

Hr. Kämmler, Hamburg, operated at once when the symptoms were serious, but he warned them against acting on a scheme. Why operate when the clinical symptoms were mild? The clinical symptoms were often a certain guide to the character of the disease. He had operated on many patients in the intermediary stages with a mortality of 0.75 per cent. Operation was always a serious procedure, and for this reason the surgeon should never follow a scheme but, should individualise.

Hr. Riedal, Jena, had brought things so far that the physicians of Jena and neighbourhood who saw a case of perityphlitis in the morning sent it into hospital at mid-day, where it was at once operated on. The result was that now scarcely anyone ever died of the disease, whilst formerly the misery of conservative treatment led many to death. An operation should be performed within the first ten hours, as, in cases not clinically serious apparently, rupture might already have taken place—as was shown not infrequently at operations. Not only early operation was necessary but the very earliest possible—die allerfrühste Frühoperation. In regard to the counting of leucocytes he totally differed from Sonnenburg and Federmann.

**VIENNA,** August 26th, 1903.

**PATHOLOGY AND TREATMENT OF ASTHMA.**

Silhe has defined asthma as a neurosis in the region of the respiratory and circulatory apparatus, requiring four factors for its production, viz.: (1) A hypotonia in the nonstriated muscles of the bronchi; (2) a similar condition in the vessels of circulation through the lung, including the heart itself; (3) a nervous process which acts on the bronchial secretion; (4) and, lastly, a fluxional hyperemia of the entire mucous membrane.

Against the fourth cause we are helpless in our treatment, although the first three can be promptly relieved by drugs ready to hand. In a typical case the following will be found to act effectually:—

**R.** Infus. folia digitalis 10°, 150° grammes.
Heroini muriati, 0°6 
Kalii iodidi, 5°

Sig.—One tablespoonful every four hours.

It should be added here that this mixture rapidly undergoes changes, and if kept any time the digitalis should be prescribed alone and not in combination with the other two components. Half an hour after the first dose the patient will find relief.

**Her.**

This drug is still on the increase as an antidote for tuberculosis. So many of these injections have been placed on the market lately that our faith is well-nigh shaken—one becomes a sceptic in every remedy put before us, no matter what its merits are. Heterol is now put up in sealed tubes containing one injection with varying strengths of solutions, as 1 per cent., 2 per cent., and 5 per cent. It is not an expensive article like tuberculin, and is calculated to cure within 100 days after 36 injections, the cost of which will not exceed six shillings.

For benefit in society practice and charitable institutions nothing can compete with it.

**STREPTOTHRIX PYEMIA.**

Horst records a case of streptothrix pyæmia in man which came under his own observation which died and revealed an undeniable condition of streptothrix.

The patient was set. 33 years, and clinically during life had all the symptoms of tuberculous meningitis.

The post-mortem revealed multiple metastatic abscesses in the brain, apparently due to original lymphatic glandular destruction in the bronchi, as there was chronic tuberculosi of the lung, with bronchial and mesenterie destruction of the glands, as well as tuberculosi of the bowel. The cause of the tuberculous symptoms seems to have been due to a streptothrix which was obtained by cultures and biological transmission to animals. The invasion of the streptothrix appears to have commenced in the bronchus, whence it invaded the lymphatic glands and finally produced pus. From these centres the fungus passed into the hematic circulation, producing embolism in the brain, which was the ultimate cause of death.

**GUMMA IN THE FEMALE URETHRA.**

Lebenbach has collected evidence in 28 cases in Neuman's clinic to prove that the various diseases represented under ulcer chronicum sive elephantiasicum, ulcer rodens, elephantiasis ulcersa, and lupus sive esthiomenas vulvae are one and the same process, as all commence by ulceration and pass through the same characteristics as exhibited in the skin and internal organs, forming a hyperplasia in the flaccid tissue and inclining to recur in the same place or attack neighbouring tissue, all of which will yield in some measure to anti-syphilitic remedies.

**Hungary.**

[FROM OUR OWN CORRESPONDENT.]

**BUDAPEST,** August 26th, 1903.

At the recent meeting of the Hungarian Neurological Society, Professor Moravecik related a few interesting cases of mental disease.

1. *Sclerosis Multiplex with Insanity.*—A hawket set. 40, was admitted to hospital with nystagmus, manifest tremor, faulty articulation, right-sided paralysis of the external muscle of the eye, increased patellar reflex, and spastic gait. Two days after admission he became very irritable, did not sleep at night, and had hallucinations, abusing his fellow-patients and spitting on them. He was therefore transferred to the observation ward, where he became quieter, but definite mental weakness remained.

2. *Paralysis Agitans with Mental Weakness.*—A smith, set. 46, who previously was quite healthy bodily as well as mentally, noticed a year ago, after lifting a heavy load of iron rods, that his right hand trembled, and this later involved the right leg and the head. Coincidently with the paralysis agitans, symptoms of weak-mindedness made their appearance. His facial expression become peculiarly rigid, and the right upper limb showed some rigidity of passive movements. Both hands, but especially the right, were the seat of oscillatory trembling, which considerably increased.
under mental influences. The attitude of the body was rigid, the movements were in some measure limited, difficult, and slow. The trunk was not bent, and neither antero-nor retrogression was present. The curve of the tremor taken up with the Marey polygraph showed the type described by Charcot and Marie.

3. Acute Hysterical Insanity.—A. K., aged 19, daughter of a lawyer, of neurotic heredity, her mother and sisters being hysterical. Three years ago, the emotion caused by the outbreak of a large fire in the neighbourhood rendered her unconscious, collapsed, and this was followed by delirium. She was in the habit of attending spiritualistic seances, and on such occasions she had several times fallen into a state of hysterical catalepsy. On May 16th, 1903, on the receipt of a letter from her betrothed, she was upset, had a feeling of oppression in the precordium, and then consciousness became dulled. She walked irritated up and down the room, spoke unintelligibly, sprang from her bed, screamed, and did not recognise her friends. She refused food, and developed obstinate insomnia. On May 19th, she was placed in the observatory ward of the St. Rochus Hospital, where she became quieter under the administration of bromides. On May 21st, in the morning, she regained consciousness, and felt as if a veil had been torn from her eyes. She failed to remember anything that had happened since the perusal of the letter in question, and wondered how she had got into the hospital. From this time she behaved quite reasonably. On examination, she was found to exhibit the stigmata of degeneration. Her forehead was low, narrow above, the pupils were unequal, but promptly reacted to light. Her tongue and hands were tremulous, the reflexes were increased. The field of vision was concentrically narrowed, the acoustic nerves were hypesthetic. There was hyperesthesia and well-marked dermographia. Touching the forehead with the finger left a circumscribed red spot. The left ovary was tender; irritabile temper.

4. Demonstrating several cases of male and female paralysis progressiva, the speaker pointed out that experience showed this pathological form to be readily propagated among women. But it must be admitted that so far as we know they are not as striking in men. He called attention to the fact that the megalomaniac form is often followed by the depressive form, and vice versa.

5. The speaker drew attention to the fact that paralytic patients often inflicted injury on themselves, partly as the result of erroneous ideas, partly in order to alleviate their pain. This at first sight might seem paradoxical, though it was a matter of fact. He exhibited a man who, besides his hypochondriacal fancies, had disagreeable feelings in his tongue, and complained that his tongue was going to fall out of his mouth. On this account he had repeatedly bitten his tongue. The speaker related a further case, wherein a paralytic patient slit up his scrotum with the fingernail, and tore out one testicle without having manifested the slightest sign of pain.

The Operating Theatres.

KING'S COLLEGE HOSPITAL.

COLOSTOMY FOR ULCERATIVE COLITIS AND SUBSEQUENT CLOSURE OF THE OPENING.—Mr. Peyton Beals operated on a man, aged about 45, whose history was as follows:—He had been in the hospital for five weeks, having been admitted complaining of intense pain in the region of the ascending and transverse colon, together with diarrhoea and the passage of large quantities of blood per rectum at intervals. He had lost so much blood that he was beginning to suffer from the loss, and was quite unable to work. The pain was most intense in the region of the hepatic flexure, and was aggravated on taking a deep breath, giving rise to a suspicion that the liver might be adherent to the colon. Soon after admission, Mr. Beals performed inguinal colostomy on the right side, the cæcum being withdrawn from the wound and a longitudinal opening made three days afterwards. On passing the finger along the ascending colon a large ragged ulcer was felt near the hepatic flexure. The ulcer was about two inches in diameter, having a very indurated edge, and was firmly adherent to the liver. It felt as if it extended through all the coats of the colon, so that no attempt was made to separate the latter from the liver. After the colostomy had been done the whole of the colon was thoroughly washed out with a mild astringent lotion of tannic acid. After three or four weeks the ulcer could no longer be felt, having completely healed up. All pain was absent, and it was deemed advisable to close the colostomy wound. This was done as follows:—The mesenteric stitch was first cut and removed and the finger was carefully introduced between the right angles to the long axis of the bowel. It was explained that the original colostomy opening in the cæcum was made parallel to the long axis of the bowel and the opening was now closed at right angles to it, the object, of course, being to prevent cicatricial contraction. The cæcum was now dropped back, and the abdominal wall closed in three layers, viz., peritoneum, muscles, and skin. Mr. Beals said that he considered the mesenteric stitch to be far superior to the older method of stitching the bowel closely to the edges of the abdominal wound, since it allowed the bowel to be so very easily freed from the abdominal walls if it was subsequently thought desirable to close the opening and drop it back. He believed it was always better to make a longitudinal incision in the preventising the sixth to the gut at first, because if it was afterwards desired to close it and drop it back the closing could be much more satisfactorily performed than when the bowel had been completely divided. Moreover, it could be closed as indicated above, that is to say, by approximating the edges of the bowel so that the line of suture was at right angles to its long axis, thus preventing subsequent cicatricial contraction and consequent stenosis. He thought that whenever a surgeon performed colostomy at the present day, one of the first things to be considered was the possibility of closing the bowel subsequently and dropping it back into the abdomen. A week after the closing of the colostomy wound the abdominal opening was healed, the patient's bowels were acting normally, and he was free from pain.

TOTTENHAM HOSPITAL.

ABDOMINAL HYSTERECTOMY.—Dr. Arthur Giles operated on a single woman, aged 43; the patient had been attending the Out-patient Department under Dr. Chappel for some time on account of her general debility, which had only latterly mentioned an abdominal pain which was constant; this led Dr. Chappel to examine her, when he found a large hard tumour rising to the umbilicus, which he diagnosed as a multiple fibromyoma of the uterus. On admission this diagnosis
was confirmed. Vaginal examination showed that the pelvis was almost filled up with the growth and hysterectomy was decided upon. A long median incision was made and the tumour exposed. It was found to have pushed up the bladder and to have stripped up the peritoneum of the left broad ligament, forming a close adhesion to the sigmoid. It was found very difficult to reach the cervix because it was pushed down laterally by a large myoma which occupied the lower anterior part of the uterus, extending deep into the pelvis and dissecting up under the bladder. During the enucleation of this tumour the bladder was opened, though this was not discovered till at a later stage of the operation. The mass on the left side was closely incorporated with a cysticovary, and both were adherent to the sigmoid. When the adhesions had been separated, the site of the adhesion on the sigmoid appeared to be the seat of a malignant growth which seemed to partially encroach on the lumen of the bowel. When the multiple tumours had been removed and the peritoneal margins were about to be united over the stump of the cervix, the opening in the bladder was seen, and it was closed with a double row of Lembert’s sutures. The remainder of the operation presented no special features and the wound was closed by the usual three layer method. Dr. Giles said that the case presented several features of interest. The indication for the operation was pain due to pressure. In view of the way the tumour filled the pelvis it was rather surprising that pressure had not shown itself also in the direction of obstruction, but there was not more constipation than is frequently found in women, and the bladder was only affected to the extent of causing some frequency of micturition. The technical difficulties of the operation were considerable owing chiefly to the way in which the anterior mass was wedged down in the pelvis and the firm fixation to the sigmoid on the left side. It was difficult to say whether the myoma, the diseased left appendages or the sigmoid growth was chiefly responsible for these adhesions. The occurrence of malignant disease of the bowel as a complication of uterine myoma was not frequent; he had met with it in one other case in which, however, it was not discovered at the time of operation (hysterectomy) and the patient developed intestinal obstruction six weeks later; it was thought that this might be due to adhesions connected with the operation, but on opening the abdomen the uterine stump was healthy and free and a large irreparable growth was found in the sigmoid; a colotomy was therefore done, but the patient died within thirty-six hours. In the present case the sigmoid growth was probably, but not certainly, malignant, but in any case he considered that it would be unwise to prolong so severe an operation as the one the patient had just undergone by further procedures on the bowel; it would be better, he thought, to watch the patient and be prepared to do a second operation on the first sign of intestinal obstruction. The bladder injury illustrated, he said, the importance of complete emptying of this viscous before operation; owing to this having been done properly in this case no leakage of urine occurred and the patient might be expected to recover without any symptoms referable to the accident.

The patient left the hospital three weeks after operation, having made a quite uneventful recovery, without any symptoms of intestinal obstruction, nor had any such symptoms occurred three months afterwards.

Royal Army Medical Corps (Volunteers).

~ Lieut.-Colonel J. E. Squire, M.D. (London Corps), has been granted the honorary rank of Colonel.
horse-ambulance. Similarly, the mortality from the same diseases averages from 9 to 12 per cent. in general hospitals, and in some American and continental institutions it has fallen even as low as 7½ per cent. This can be explained by the fact that patients attend the ordinary medical or casualty departments of the hospitals perhaps with nothing more than a high temperature and a suspicious history. They are immediately admitted into the wards, when possible, and the presence of the disease is confirmed a day or two later, but they have no long distance to travel. The establishment of out-patients' departments in connection with the infectious hospitals would go far to obviate this more than apparent disadvantage, while it would also tend to relieve the congestion of the general hospitals and, at the same time, assist in minimising the risks of infection which are constantly run by the latter institutions.

It might be urged that such a departure would presume or encourage additional or special medical knowledge among the general public which would not always, perhaps, be desirable, and that cases would certainly find their way to the infectious hospitals which should have gone to general ones. These objections are not of sufficient weight when placed side by side with the advantages which would be gained by the patients themselves and the public at large were such annexes to be constructed. Not only would enteric patients benefit by this procedure, but those suffering from other infectious diseases also. The child gasping with laryngeal diphtheria could then be taken by its mother directly to the fever hospital, instead of going to a general hospital only to be refused admission, and having to wait hours before the arrival of the ambulance. Small-pox suspects or contacts could be directed to attend at these departments, if necessary, during their period of enforced or voluntary quarantine. We beg to submit the suggestion for the consideration of the Metropolitan Asylums Board in the hope that such an experiment might prove practicable and also that it might help to increase the popularity and the utility of the work of that body as the custodian of the public weal.

THE OUTLOOK OF THE PHTHISICAL.

In endeavouring to establish the value of any method of treating pulmonary tuberculosis, we are far to have recourse to statistics if we wish to demonstrate a prolongation of life. The ordinary statistics, based on the returns of special institutions or compiled from the returns of life insurance companies, are open to the objection that in calculations based on the average duration of life from the onset of the symptoms to death no account is taken of the patients actually living at the date at which the investigation terminated. Dr. Stadler, of the Marburg Polyclinic, has adopted a more rational plan which appears better calculated to afford a fair estimate of the average duration of life in such subjects and incidentally of their degree of incapacity for work. Taking 670 cases of phthisis in the first and second stages, whose prospect of life calculated in the usual way would be 3½ years, he establishes the percentage of survivors to the total number of patients year by year for nine years, as well as the percentage of deaths during the same period of time. On this plan every patient who is living at the end of eight years is reckoned as living during each of the preceding years since the onset of the disease. He found that about two-thirds of the patients are still alive at the expiration of four years, and it is not until the seventh year that the number of deaths rises approximately to that of the living. He infers that in regard to the particular class of patients (peasants and working men) treated at this institution the prospect of life is about seven years. With regard to the capacity for work of these sufferers, he calculates that, roughly speaking, half of them are able to perform work of some sort as late as the fifth year, that is to say, they are not incapacitated for work to such a degree as to be reckoned invalids under the terms of the German law of insurance against “invalidity.” Incidentally, Dr. Stadler remarked that the prospect of life, i.e., the average period of survival, is longer in females than in males, six years in the latter and seven in the former. This is only what one would expect in view of the greater opportunity enjoyed by women of taking care of themselves, as compared with men who continue to work until disabled by the malady. The longest periods of survival were noted in subjects between fourteen and seventeen years of age, the shortest between forty and sixty-nine, the average in the latter group being only five years. Occupation appeared to exert a marked influence on the duration of survival. Home workers averaged seven years, while subjects who worked in the open, or who were exposed to dust, only averaged six years. Exposure and dust appeared equally prejudicial to the sufferers, in so far as the progress of the disease is concerned. Dr. Stadler’s next step was to apply his statistical method to the inmates of a neighbouring sanatorium, but it was impracticable to continue his observations beyond the fourth year. He found, however, that during the first three years of sanatorium treatment the mortality was one-fifth below the average of out-patients, but the benefit was only temporary, since in the fourth year the proportion of deaths among the inmates was already higher than outside. In respect of their capacity for work, the proportion of patients in the fourth year still able to follow their occupation was 2½ per cent. higher in those treated in the sanatorium than in outsiders. The general conclusion to be deduced from these carefully thought out statistics is that the sanatorium treatment has for effect to prolong life and the ability to work by from a fifth to a quarter. It would be interesting to apply this method to the inmates of our own sanatoria, for we believe that the results would work out disappointedly than is the case in Marburg. Moreover, calculations of this kind can only apply to the special...
classes of patients under observation, so that, however interesting they may be, their practical utility is open to question.

POPULAR VIEWS OF VIVISECTION.

The Daily News, suffering doubtless from the annual dearth of matter that characterises the autumnal holiday season, has started the discussion of vivisection in its correspondence columns. The subject is one that leads itself readily to popular treatment. It is easy to draw detailed pictures of experiments upon lower animals in such a way as to shock every humane reader, and to run the whole gamut of his better emotions. The moral aspect of vivisection, however, will have to be determined upon grounds of reason as apart from those of sentiment and mere emotion. From the sentimental standpoint presumably, anti-vivisectionists admire pigeons, larks, salmon, deer, lambs, calves, and all harmless and beautiful creatures of the Creation generally. Sentimental admiration and kindness, however, have so far given way to reason as to permit them to slay and kill any or all of the animals mentioned for the sake of food. Nay, more, the killing and slaying, whether performed in the slaughter-house or out in the open by way of sport, is often conducted under circumstances that inflict a vast amount of unnecessary pain upon their unhappy victims. Then, again, these sentimental objectors to vivisection do not hesitate to use decorations for their bodies obtained from living lower animals at the cost of pain and at times under circumstances of revolting cruelty. Your true anti-vivisectionist, however, declines to discuss the right assumed by mankind over the lives and the bodies of lower animals for purposes of food, sport, convenience, or personal decoration. His mind is so concentrated upon the mote in the vivisectionist's eye that he fails to recognise the beam that obscures his own vision.

The Daily News, following the classic methods of modern journalism, opened the anti-vivisection correspondence with a shot from a big gun, to wit, Mr. William Watson, the poet. Of all persons in the world a poet is, perhaps, the least suited for the calm discussion of a somewhat tangled ethical question of this kind. The amiable and gifted gentleman who set the ball rolling in the present instance has proved no exception to that general rule. He has, indeed, made an eloquent exposition of the sentimental side of the matter, but of sound argument there is a scant allowance indeed; when one takes into consideration the sweeping nature of his conclusions. The pith of Mr. Watson's contention is that man has no right to inflict unnecessary pain upon lower animals for experimental purposes. Why should he draw the line at scientific experiment? The infliction of unnecessary pain, he says, is indefensible in the case of scientific investigation, although conducted with a view to the safety and protection of mankind. Why, then, is the infliction of unnecessary pain to be condemned when inflicted upon lower animals for the sake of sub-sistence, of vanity, of recreation, or of utility and convenience. The point thus raised is of such a crucial nature as to demand, in our opinion, a clear and adequate settlement before the discussion can go further. The old question of fact has already cropped up in the course of the discussion, namely, whether any benefits have actually accrued to mankind through the knowledge derived from experimental investigations. The whole progress of scientific surgery and medicine ultimately depends on that of physiology, which in turn depends on facts derived from experiment. In this indirect way, and also directly, both physicians and surgeons at times resort to vivisection, in order to test, to found, or to modify their theories and conclusions. To take an instance, it is desired to know the exact origin of fluid effused in pleurisy. By inoculating a guinea-pig it may be definitely ascertained whether the malady is or is not of tuberculous origin. The information thus gained by a simple vivisection experiment may quite conceivably be of supreme importance to a number of human beings. Of what value are many guinea-pigs to one man? In the course of his lifetime the anti-vivisection does not hesitate to eat droves of oxen and shools of fish; why then, should he boil over with rage and indignation when a few lower animals are sacrificed under legal safeguards in a laboratory with a view to his ultimate bodily benefit? It seems to us that the anti-vivisectionist fails to view his general relationship to the lower animal world with the same spectacles that he assumes in order to inspect the special conditions that exist between the scientific investigator and the lower animals.

Notes on Current Topics.

Vivisection and Theology.

In these days when the benefits which science would confer are received with ingratitude by many, and the methods by which these benefits have been obtained are maligned and misinterpreted by more, it is quite refreshing to learn that there still remain a few who do not cherish the belief that experimental medicine consists in violating every known doctrine of Christian theology. In a recent paper in the Human Review, the Right Rev. Mgr. J. S. Vaughan appears as a true champion of scientific vivisection. Well-worn and homely as his arguments are, they serve so admirably as a popular exponent of the aims of experimental medicine and the necessity for its practice, that we would fain quote them here as illustrating the best position a medical man can take up when challenged upon the matter. "Here is, let us say, an ordinary good-natured and able physician," writes Mgr. Vaughan, "whom we will call Dr. X. His whole aim and object is to diminish pain and to allay suffering. It is not in his power to destroy it, therefore he directs his efforts to alleviate it. He knows that men are by far the most sensitive
of sufferers. He knows that they are subject to certain painful diseases. He has good reason to think that a certain treatment would bring great relief, and perhaps even produce a cure. But his reasoning may be defective, and he cannot ascertain with any degree of certainty whether his opinion be well-founded unless and until he can test his theories by actual experiment. That is to say, he must actually apply the remedies. It is essential that he should make the experiment on a living organisation of some kind. But upon whom? Well, there are but two classes of creatures to choose from. We must make it either upon a human being or else upon a beast; either, let us say, upon a sick child, or upon a rabbit. The anti-vivisectionist objects to all experiments on animals, and in effect, answers, 'The experiment must be made on the sick child, not on the rabbit!' And this is why we call the anti-vivisectionist cruel. We, on the contrary, hold that the experiment should be made on the rabbit or other beast, and not upon the unfortunate sick child. Yet, on that account, we are called cruel. Our reason for maintaining this view is, first, because the beast is less sensitive to pain. Secondly, because its loss of life, should the experiment prove abortive, is of far less consequence. Thirdly, because the child is our very own flesh and blood, and a member of our great human family, and has immeasurably greater claims upon our pity. Fourthly, because God has given men dominion over the beasts of the field.' For these and other reasons, the necessities for the use and practice of vivisection with all mercy and tenderness are considered to be fully justified by this revered champion. *Experimentum cit in corpore vii.*

**The Treatment of Baldness.**

Most of us who have at any time frequented the larger hair-cutting establishments in the Metropolis are acquainted, by sight at any rate, with the imposing gentleman in a frock coat, who wears moustaches half a yard long and a crop of hair on his head which would not shame the most unsuccessful of literary men. He is spoken of by the assistants in reverent tone as the 'hair specialist,' and if we are unfortunate enough to be getting a 'little thin on the top, sir,' his advice is sought. He recommends the application of a certain wash, the price of one bottle being a guinea. This appalling person is, to a great extent, the natural result of the indifference and carelessness of legitimate physicians as regards the treatment of baldness. It is a fact that medical men seem hardly to grasp, that baldness is a disease, and that, before old age at any rate, it is curable. At the same time it may be freely admitted that the treatment is certain to be prolonged, and will require the greatest of patience both in the physician and the sufferer. The lines indicated in most cases, if not all cases, are cleanliness, antisepsis, and stimulation. Dr. Bernheim, of Philadelphia, (a), who has treated a great many cases with success, recommends scrubbing with tar soap for several minutes to remove all dust and dandruff, thorough rubbing with a spirituous solution of mercuric chloride, and finally the application of a stimulant antiseptic hair oil (for instance, oil containing salicylic acid).

**Gastric Cough.**

It was by Willis that the appropriate name of "stomach-cough" was applied to the reflex determined by irritation of some portion of the area supplied by the pneumogastric nerve. Since the time of that distinguished observer many authorities have written upon the subject and speculated as to its causation. The gastric mucous membrane is generally supposed to be in a state of hyper-excitability in order that various stimulating agents, usually ingesta, may give rise to the cough. The swallowing of ice may, in predisposed individuals, be sufficient, while, as Dr. Louis Revol, of Lyon, points out, in the *Gazette des Hôpitaux*, the symptom is often seen in gastric ulcer, and also in some cases of cancer of the stomach. There are many theories regarding the origin of the gastric cough, some observers holding that it is produced by causes acting outside the stomach, as, for instance, an abnormal flow of secretion from the nasal fossae; while others believe that it is due entirely to intragastric excitation. A morbid condition of the mucous membrane appears necessary for the production of the cough, and the usual stimulus is the presence of food in the stomach, acting upon the terminal nerve-filaments of the vagus. Its most important characteristics and those which are of assistance in arriving at a differential diagnosis are its dryness, the absence of expectoration, its inutility with regard to relieving the respiratory passages of any morbid product, and its spasmodicity. Care must be taken not to confound it with a variety of cough due to pyrosis, in which acid fluid from the stomach mounts up the oesophagus and reaches the inter-arytenoid space, which is essentially a "cough-producing area," according to Pechkranz. In such there will be other symptoms of acid dyspepsia. Laryngeal cough has a more raucous or strident quality. The chief therapeutic indication is to diminish the sensibility of the gastric mucous membrane with cocaine or morphia, and to lower the excitability of the nerve centres by the administration of the bromides.

**Empyema and Sinusitis of the Antrum.**

Under the term empyema of the antrum two very different conditions are usually included—namely, chronic sinusitis and true empyema. Although both are characterised by the presence of pus in the antrum they are fundamentally different in regard to prognosis and treatment. In sinusitis the pus is secreted by the walls of the cavity, the mucous membrane lining which has undergone proliferation with the formation of vegetations which more or less fill it. In empyema, on the other hand, the pus is from some extraneous source the antral walls being quite healthy, and this even although the accumulation of pus has been

(a) *American Medicine*, July 4th.
allowed to remain for some time. It is obvious that while empyema is a lesion which is amenable to mere evacuation of the purulent contents and removal of the cause of suppuration, chronic sinusitis can only be cured by a radical operation. Under these circumstances it is highly important to make the differential diagnosis between the two morbid states. One ready means of arriving at a conclusion is that suggested by Mahu, who withdraws the pus by means of a trocar thrust into the sinus through the lower nasal fossa, and takes advantage of the opportunity to ascertain the capacity of the cavity by measuring the quantity of fluid that can be injected, having previously washed out the cavity. Whereas in chronic sinusitis the capacity may be reduced to a fraction of a cubic centimetre, in simple empyema the antrum will hold about 4 cc. Moreover, after evacuation of the pus, if recourse be had to transillumination the translucency is normal in empyema but remains manifestly obscure in chronic sinusitis, owing to the thickening of the walls. By this comparatively simple procedure it is, therefore, possible to indicate with scientific precision the nature of the lesion and the appropriate treatment.

Infection by Nematodes.

It is now three months since a case of general infection with a nematode associated with hypertrrophic gingivitis was reported in the *Lancet* (a) by Mr. J. Dencer Whittles, Lecturer in Dental Histology and Pathology in the University of Birmingham. Mr. Whittles has pursued the subject still further, more especially in the direction of blood examination, with the results which he has embodied in the *Midland Medical Journal*. His investigations, upon which much care and labour have been bestowed, are of great importance, indicating as they do the prevalence of an epidemic of nematode infection in Birmingham, the extent of which it is impossible, at present, to estimate. The blood of three different shop-assistants, who were in the habit of handling vegetables and fruit, was examined and found to contain the parasite. Several samples of milk were also proved to be infected. Clinically, the symptoms bear a close resemblance to scabies, but without the cutaneous and the distribution of the latter infection. The presence of the nematode in the blood gives rise to severe itching of the skin which is generally experienced first upon the shoulders and flexor aspects of the arms. A papular eruption of a pruriginous character then manifests itself. The parasite was found in the blood in these cases. The question arises as to whether the malady is of the same nature as that seen on the West Coast of Africa which bears the name of "craw-craw," and in which Suregon O'Neil discovered a filarial worm. Owing to the transparency of the parasite some patience is required in order to avoid overlooking it, but in films stained with methylene blue it can be recognised quite easily. From the public health aspect it is of the greatest importance that the investigation into the source of the epidemic should be vigorously pursued, and, as Mr. Whittles suggests, that blood examinations be made in any suspicious case.

Plague Disinfection.

The method of disinfection which has been proposed to be applied to Chinatown, San Francisco, in order to destroy the plague, is nothing if not thorough. In the graphic words of Dr. Hutchinson's report to the Oregon Board of Health, "sterilisation by dry heat at 400° is the only cure for its filthy condition." After a description of the actual conditions which are present through the whole of the Chinese quarter, not only in San Francisco but in every Chinese colony on the West Coast of America, he comes to the conclusion that it is absolutely impossible to think of cleansing such dens by any other means than total destruction by fire. It is not only the ideal, but the only practical and safe course." Ideal it may be, but it is we fear, hardly practicable. To go no further, housing must first be provided for the inhabitants of the condemned quarter—no easy task, when it is remembered how these people flock together. And even if suitable dwellings could be provided, would they not in a few years be in quite as insanitary a condition as those that had been destroyed? We remember hearing that in a certain Indian sea-port some years ago such an experiment actually occurred. By accident the principal suburb, to which plague was confined, was burnt to the ground, not without jubilation among the sanitary authorities. For some months there was no plague, but this condition did not last, and within two years the place was as bad as ever.

Mental Disorders and Nasal Polypi.

A connection, more or less direct, has many times been proved to exist between nasal polypi, the presence of which may be entirely latent or unsuspected, and various forms of neuroses, including spasmodic asthma and hay-fever. These ailments have been repeatedly cured by the removal of the growths. Their association with mental disorders has not been prominent, nor, indeed, has it been widely recognised. Eleberg, of New York, in 1863, drew attention to the relation between affections of the nasal mucous membrane and mental conditions, and the subject has been dealt with more recently by Renault and Natier. A case, illustrating the immediate beneficial effect of the removal of nasal polypi in melancholia, described by Dr. Royet (a) may here be quoted. The patient was a man, aged 38, with a good family history, who for three years had suffered from feelings of coldness in the left ear and paroxysmal headaches, which gradually increased to such an extent that he felt himself quite unequal to performing his duties as a porter, and ultimately a condition of melancholia with suicidal tendency and auditory hallucinations developed itself. A physical examination revealed nothing abnormal in the important systems, but there were numerous mucous polypi in the nasal fossae of both sides.

(a) Lancet, May 22nd, 1903.

(a) *Le Progrès Méd.*, August 15th, 1903.
These were removed by the cold wire and their bases touched with the galvano-cautery at several settings. After the first, the patient expressed himself as feeling much brighter and he had a calm sleep. In the course of a few days his ideas became quite rational, his headaches disappearing at the same time. Dr. Royet draws an analogy between the effect of the polypi in aggravating or producing the mental disorder and the heavy, stuffy feelings, in some cases even accompanied by considerable depression of spirits, associated with an ordinary “cold in the head.” Truly we might say with Celsus, “Si in naves destillat, tenues per has pruina profusit, capit leviter dolet, gravitas ejus sensitur.”

**Fatal Sea-Sickness.**

Notwithstanding the almost universal nature of the malady, it is notorious that even when it assumes a grave form, death from sea-sickness is, happily, very rare. The untrustworthiness of the many remedies which have been vaunted as preventives, and the failure of one remedy to give relief in a given case when it has proved successful in another, are owing to the varying pathology of the affection in different individuals. The same theory of the production of mal-de-mer will not hold good for everyone. In one it may be an aggravated form of vertigo of cerebral origin, in another it may be due to the sudden falling of the abdominal viscera, owing to insufficient support afforded by the abdominal muscles, while in a third it may be caused by the irregular contractions of the diaphragm, which, by pressing upon the stomach, induces that organ to discharge its contents. A few instances in which fatal result has occurred have been lately reported in the Press; in one of these death was produced by cardiac failure when the organ was fatty, and in another it was due to the rupture of a blood-vessel. These are probably the two most common ways by which sea-sickness may be the primary cause of death. The strain upon the heart and vascular system consequent upon the repeated act of vomiting may be directly answerable for the fatal issue in conditions of atheromatous or fibroid or fatty degeneration of the heart. When the illness is prolonged death may occur from exhaustion, owing to the long-continued strain.

**The Fear of Eating.**

Many individuals who are martyrs to their digestive organs literally starve themselves simply because they are afraid to take this or that article of food, knowing from experience that by so doing they will only suffer agonies of pain. Others abstain from fear of possible bad after-effects from partaking of an untried dish or even of accustomed food should this be served or cooked in a manner contrary to their usual habits. This condition, which is only too common, is described by Professor Max Einhorn, of New York, as “sitophobia,” or the fear of eating, and in the American Journal of the Medical Sciences he points out that even when no pain is felt, but merely vague sensations of general discomfort, such people still abstain from eating, and thus ultimately arrive at a state of relative or actual inanition. Sometimes this sitophobia, like most other “phobias,” is of cerebral origin. The treatment of inanition from this cause is very difficult, but it must be undertaken energetically, as the general nutrition of many dyspeptics is much below par, owing to their having subsisted, perhaps for a considerable period, upon far less food than the normal physiological quantity. Professor Einhorn applies the term “subnutrition” to such a state, and points out that the first thing to accomplish is to combat the sitophobia, should this exist. Persistent efforts must be made in order to encourage the patient to take food, even though it should cause him pain. After a short time it will generally be found that the pain will disappear pari passu with the improved nutrition.

**The Finsen Light Cure.**

The Cootehill Board of Guardians at their meeting on the 14th ult. made the excellent suggestion that there should be established in Dublin or some other convenient centre an institution for the treatment of cancer and such growths by the Finsen light, to which patients could be sent from every union in the country, the expenses to be borne by a rate in aid, levied over the whole country. By this scheme the funds of no private charity would be entrenched on. There is the same principle in the claim on the public by a carcinomatous patient by onesuffering from typhoid, and by collecting the carcinomatous, epitheliomatous and lupous cases into a metropolitan or provincial institution, the expenses incidental to treatment would not be so very heavy. The establishment of such Finsen hospitals would materially assist in the clinical study of the disease, and enable the members of the profession to more accurately estimate the value of the treatment. It would be in harmony with the spirit of the Medical Charities Act, and would demonstrate to the people that every aid scientific progress can afford is at their service. It would also induce patients to come forward in the earlier stages of the disease, when there is more hope of improvement. We congratulate the Board on taking the initiative on this subject.

**Is Hernia an Accident?**

We have received a number of communications bearing on the recent decision of the Court of Appeal declaring that hernia may be an “accident” in the sense accorded to the term under the Workmen’s Compensation Act. It is urged, for instance, that although the occurrence of a hernia infers a pre-existing weakness of the abdominal parietes, the defect is only relative and not absolute, in the sense that had there been no undue muscular effort the rupture would not have occurred. A man’s bones may be weaker than the normal, yet a fracture would count as an accident. Or, again, a man who has once dislocated his shoulder remains liable thereto on comparatively slight violence, yet we presume he could...
The Medical Press.  

NOTES ON CURRENT TOPICS.  

Sept. 2, 1903.

claim compensation every time it occurred.  
Nevertheless, the decision opens wide the door to a number of delicate problems.  
A sudden strain may determine cerebral or pulmonary hemorrhage in a man with diseased arteries, but it would, we venture to suggest, be absurd to describe such an occurrence as an accident in the ordinary sense of the word.  
But if not, where are we to draw the line?  
The decision materially modifies the responsibilities of the employer, and will inevitably pave the way to much troublesome litigation.

The Missing Lady Doctor.

NOTWITHSTANDING disgracefully sensational reports of the movements and alleged discovery of Miss Hickman, who so mysteriously disappeared from the Royal Free Hospital upwards of a fortnight ago, no trace of her whereabouts has so far been lighted upon, and we are still reduced to conjecture.  
Judging from the hysteric letters that have appeared in the Press at intervals during the past few days there is a neurotic element in the family history which lends colour to the plausible suggestion that she may be suffering from the curious mental condition known as "automatic wandering," instances of which are not rare in medical literature.  
Several cases of the kind are related by Dr. W. S. Colman in the current issue of the Lancet.  
The principal argument against this hypothesis is the length of time that has elapsed since her disappearance, a circumstance which, indeed, almost precludes an aberration of this description.

Arsenic in Sweets.

Arsenic crops up in the most unexpected places, and it has no sooner been exorcised from one medium than it is discovered elsewhere.  
Wall papers, preserved vegetables, beer, and now sweets.  
Mr. Otto Hehner, public analyst, has detected "notable quantities" of arsenic in sweets purchased in the Isle of Wight in the oxide of iron coating, which gives them a misleading appearance of chocolate.  
It is reassuring to learn that the substance is not present in sufficient quantity to justify the apprehension of arsenical poisoning, unless in the hands of an unusually voracious consumer of sweetmeats, but the circumstance suggests caution in basing medico-legal conclusions on the presence of minute quantities of the poison in the bodies of persons who have died with symptoms which appear to point to arsenical intoxication.

Latent Gonorrhoea.

The diagnosis of acute gonorrhoea is, as a rule, easy enough, but it is necessary to bear in mind that in a certain proportion of infections, especially in those who have had previous attacks, the classic symptoms may be ill-marked or even completely absent, a class of cases to which the term "latent" or "torpid" gonorrhoea has been applied.  
There may be little or no discharge, even the matutinal drop being conspicuous by its absence, and the patient experiences no burning on miction; in fact, the only objective sign may be congestion and swelling of the margin of the meatus.  
The existence of gonorrhoea may escape notice until attention is called thereto by the occurrence of epididymitis, bubo or a sudden attack of prostatic trouble.  
Cerufugation of the urine, however, enables the bacteriological diagnosis to be made, and should be resorted to whenever the diagnosis is doubtful, not only in the interest of the patient, but also in that of the community.

The Psychology of Tuberculosis.

It is not an exaggeration to say that each disease has its psychology as well as its physiognomy, and in this connection some interesting observations have been made on subjects actually, or who subsequently became, tuberculous.  
All practitioners are familiar with the buoyant and sanguine character of the phthisical patient in the antepenultimate stage of his malady, but apart from that pathetic feature there has been remarked in such subjects a greater or less degree of impairment of the sense of responsibility, their moral being is depreciated in tone, not only in respect of sexual indulgence—though this is a matter of notoriety—but also in regard to such elementary moral principles as truth and honour.  
Speaking generally, it may be said that the tuberculous subject is less moral and more emotional than the normal.  
It would, however, be absurd to pretend that mental disturbance in some degree is the necessary and constant appanage of phthisis, for one's daily experience from start to finish is convincing of the contrary.  
The discrepancy is probably to be explained on the assumption that the distressing mental characteristics just referred to present themselves only in persons who, in addition to being phthisical, come of a neurotic stock.  
In these the irritating effects of the presence of tuberculous toxins in the blood may determine emotional vagaries.  
It must be remembered, too, that in a certain proportion of cases of phthisis the vulnerability of constitution is derived from parental alcoholism or syphilis, which, it is well known, are apt to entail instability of the nervous system.  
There is still another class in whom the tuberculous process is not limited to the lungs, but invades the meninges or even the cerebral parenchyma itself, the mental symptoms being directly caused by the physical effect of such deposits.

The Surgical Treatment of Puerperal Pyemia.

Puerperal pyemia is such a serious and indeed well-nigh hopeless condition, once it has obtained a hold, that one is justified in trying any means, however dangerous in themselves, to rescue the sufferer from her otherwise inevitable fate.  
So far, the seropathie treatment, though promising, fails to arrest the process in the great majority of cases, either because it is not resorted to until too late a period or because its effects are limited to particular pyogenic organisms, so that in mixed infections, to which group cases of puerperal infection usually belong, the serum does not fulfil the entire
therapeutical ground. Certain surgeons, among them Trendelenberg, have adopted the plan of cutting down upon and ligaturing the thrombosed ovarian vein. Michels reports one such case followed by recovery, but in four out of five of Trendelenberg’s cases a fatal result ensued. Under these circumstances the operative treatment of this infection is hardly likely to become general, indeed, in view of the state of a patient whose blood has become the culture medium for the septicagmas, no surgical procedure is likely to prove of much service. Our hopes are rather in the development of the seropathic treatment, which, after all, is as yet only in its infancy.

A Novel Malingeriing Device.

The artifices resorted to by soldiers and others who wish to evade their responsibilities testify to much ill-employed ingenuity, and in countries where military service is compulsory no slight degree of perspicacity is required of the medical examiners to determine the validity of the lesion, and more particularly its spontaneity. A Russian military surgeon relates a case which recently came under observation in which a young man claimed exemption on account of a hydrocele. The scrotum was much distended and on the right side there was a scab, beneath which could be felt an absence the size of a pigeon’s egg. On palpating the swollen scrotum distinct crepitation was heard, which gradually subsided in the course of a few hours and at the same time the scrotum returned to its normal size. It transpired that the scrotal distension had been brought about by blowing air beneath the skin through a goose quill, the aperture being closed by a sort of putty. This device is worthy of figuring in the malingerers’ museum, since it opens up a new vista of possibilities in this direction.

A Curious Case of Arsenical Poisoning.

A man was recently admitted to Professor Janovski’s clinic at Prague for cutaneous tuberculosiis complicated by tuberculous manifestations of the bones and lymphatic glands. He had been taking arsenic in doses of a fifth of a grain three times a day without inconvenience. On this occasion he was given a subcutaneous injection of a fifth of a grain of arsenic acid, the dose being subsequently increased in such wise that in nine days he had received in all fifteen milligrams, about a quarter of a grain, of the drug. Thereupon the sites of the punctures became the seat of extensive subcutaneous extravasations of blood and the rest of the body was covered with petechiae. The treatment having been suspended, the blood underwent absorption and things returned to normal in the course of a few days. The author attributes this unusual manifestation to idiosyncrasy on the part of the patient towards arsenic administered hypodermically.

Captain C. E. P. Fowler, R.A.M.C., has been appointed Assistant-Professor of Military Hygiene at the Royal Army Medical College.

Dr. Robert Koch, who is pursuing his researches on “sleeping sickness” in Bulawayo, has decided to carry on the work until early next year.

Miss Mary C. Lowell, of Boston, rejoices in the probably unique distinction of having acquired degrees which entitle her to practise both law and medicine.

Mr. J. P. Byrne, L.R.C.S.I., House Surgeon, Dewsbury Infirmary, has been appointed House Surgeon to the Provincial Hospital at Port Elizabeth, South Africa.

Mr. R. Fox Symons, M.R.C.S., L.R.C.P., D.P.H., Acting Medical Officer of Health for the Transvaal, has been appointed Inspector-General of Health of the Transvaal.

Madame Gaussel has been appointed Chef de Clinique of the Obstetrical and Gynecological Department of the University of Montpellier, this being, we believe, the first occasion on which this coveted post has devolved upon a woman.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

GLASGOW.

NURSING HOMES IN GLASGOW.—As a result, in some measure at least, of an article which was published in The Medical Press and Circular a few weeks ago on the subject of nursing homes, and which should cause some members of the medical profession who are largely interested in these homes to pause and consider their position, a letter appeared in the Glasgow Herald recently, advocating the establishment of a nursing home or homes for a class of people who are not in a position financially to avail themselves of any of the existing homes, of which there are quite a number, where the charges range as a rule from £3 3s. to £5 5s. per week. The letter evoked a remarkable amount of sympathy, and cordial approval of the scheme suggested, as was evidenced by the large number of letters which appeared in the Herald for a week or so following, as well as letters received privately from ladies and gentlemen belonging to the laity, and also from various members of the medical profession. At the Royal Western, and Victoria Infirmaries, as is shown from the reports issued weekly, there are probably from six or seven hundred patients awaiting admission. The report of the Samaritan Hospital shows from eighty to ninety women waiting for admission. This is quite a serious state of matters, and how it is to be remedied is a problem which is causing the managers of the different hospitals considerable anxiety. It will be some years before the reconstruction and enlargement of the Royal Infirmary is completed. An extension of the Samaritan Hospital is to take place soon, and for which a bazaar will be held in the winter under Royal and other distinguished patronage, and in behalf of which numerous American and Gipsy teas, &c., have been held at the residences of leading citizens, all of which will result in a great financial success for this comparatively young but useful hospital. All this said, the question remains, what is to be done by way of relieving the very urgent pressure which is at present taxing the accommodation in our hospitals to their utmost? It is thought that nursing homes in various districts of the city for those whose means are limited, such as clerks, shopmen, and shopwomen, dressmakers, and such-like, where the charges would range from £1 1s. to £2 2s. per week, would in some measure help to solve the problem. There are a class of people, again, who have no claim to become inmates of the hospitals, being neither rich nor poor, for whom these homes would be in times of sickness very suitable, and, of course, there are a great many with limited incomes.
who from a spirit of independence would rather pay a moderate charge in a nursing home than enter any of our hospitals, and for these people who like to pay their way as they go along every possible facility should be provided for them getting into homes at such rates as would be necessary for a hospital arrangement. As a result the corresponding increase, which has already appeared, it seems that some of the existing homes provide in certain cases limited accommodation at a guinea to two guineas per week, but such cases we fear are very few in number. A small house for women was opened a few months ago by one of two lady doctors, where we understand the charges are from 7½ to £2 2s. per week, but it is a small affair at present, having only a few beds. We are glad to state that no one who is well known for his habit of generous acts of head and heart, has promised the scheme his support. It will at no distant date take practical form, if not on a comprehensive scale with district nursing homes, at least on a smaller one, as a beginning. A large house, admirably situated, will be furnished and fully equipped as a nursing home for the class of people we have referred to. We may further say that there are ladies and gentlemen willing to give their services in various capacities in connection with the project without remuneration of any kind, from the position of matron to that of nurse, and in other ways. It is very pleasing to record that the scheme was first carried out on a large or small scale, has "caught on" in a way that is most gratifying and indicates very emphatically that the want is a much-feel one. From the amount of professional support tendered, its success, we may venture to predict, is assured.

BELFAST.

LOCAL GOVERNMENT BOARD INQUIRY AT LISBURN.—A sworn inquiry has been opened at Lisburn by Dr. Gilbourn, the Local Government Board inspector, relative to certain charges of neglect made by Dr. Jefferson against Nurse Hopkins, midwife. There has been considerable friction in the dispensary work for some time past, but so far as the evidence has disclosed, there was nothing which might not have been smoothed down by a little mutual forbearance. The inquiry is still proceeding.

LURGAN UNION INFIRMARY.—A special report was read at the last meeting of the Lurgan Board of Guardians on the increased expenditure on the infirmary. It appears that the consumption of a number of things has steadily risen for the past five years, and the normal expenditure by now 11 per cent. in bread, 38 per cent. in beef, 29 per cent. in sweet milk, 175 per cent. in eggs, and 289 per cent. in whisky. It seems that a great deal of the increase has taken place in the infirmary, over which the master has no control. The officers, who are only there for a few hours each day, cannot be held responsible, and a strong case seems to have been made out for the appointment of a responsible superintendent nurse.

CONVERSATION IN BELFAST.—THE PROPOSED SHELTERS.—The opposition to the proposed shelters for consumptives in the Ormeau Park continues to grow in strength. A public meeting of the inhabitants near the park was held on Friday evening, the 28th ult., to protest against the scheme. The proceedings were, as the newspapers mildly put it, most inharmonious. Dr. Charles Kevin presided, and a letter was read from Professor Lindsay, stating that he saw grave objections to this no doubt well-meaning scheme, both from the point of view of the public and of the consumptives themselves. The Ormeau Park was too low and damp to suit such patients. A letter from Dr. Almack Browne also expressed strong disapproval of the scheme. Dr. Davison moved a resolution opposing the meeting to oppose the scheme. So far medical opinion was unanimously opposed to it, but unfortunately for the profession, an amendment was proposed by Dr. Davison and seconded by Dr. Ruske (both local practitioners) to the effect that the meeting was in favour of such shelters, not only in the Ormeau Park, but in every park in Belfast. Dr. Davison met with great opposition from the meeting, and the amendment was lost by a large majority, but before the meeting closed the excitement became so great that several policemen had to be called in to keep order.

The whole question is, no doubt, one on which opinions may well differ; but it is certainly a matter for regret that medical men should display their differences at a public meeting, exposing themselves to very free personal remarks from the back benches, which few remarks were greeted with loud laughter by the audience.

LITERATURE.

MAX EINHORN'S DISEASES OF THE STOMACH. (a)

This treatise opens with a short chapter on the anatomy and physiology of the stomach. Then follow a chapter of 100 pages devoted to methods of examination. First of all we have the interrogation of the patient, then the physical examination, including esophagoscopy, gastroscopy, and transillumination of the stomach, and then finally the examination of the gastric functions and contents. The third chapter treats of dietetics, and here the author points out that patients suffering from gastric disturbance should be content with large amounts of food as in health and the same kinds of food stuffs, the only differences being in their selection, form, and special preparation. In treating the diseased condition one may either give the organ perfect rest, or strengthen it by adaptation of the diet. He makes it a rule to forbid nothing save what is absolutely harmful in any given case, nor would he change the number of meals nor yet the hours of feeding, except there should be some very special indication for so doing. The author wisely states that so commonly observed ostricts in dyspeptic conditions, is quite permissible, as its digestion does not take place in the stomach, but in the small intestine. Again, bread and other food stuffs rich in carbohydrates are often forbidden lest fermentative processes should be thereby set up, but the cases in which there is a considerable amount of fermentation going on in the stomach are rare. Carbohydrates, in the form of sugars, really lessen the acidity of the stomach, and are therefore advantageous in cases of hyperchlorhydria. In all cases attended with hyperacidity, the amount of the nutritious food should be increased and the use of beverages greatly limited. In dilatation and gastropilsis, small and frequent meals, with little liquid nourishment, are indicated.

Chapter IV deals with the local treatment of the stomach by lavage, douching, and spraying. The gastric spray is employed wherever it is necessary to apply toxic or irritating agents to the gastric mucous membrane, as by this means a large area can be covered by a comparatively small amount of fluid. The author describes his power-blower, which he introduced some four years ago to facilitate the introduction into the stomach of substances which are either insoluble or only soluble with great difficulty. By means of such medicaments as bismuth, protargol, and suprarenal capsule can be directly insufflated. The practical application of electricity to diseases of the stomach is next taken up, and considerable indication is given for the use of the electrospray. Following this we have chapters on the various diseases and disorders of the stomach, each being thoroughly and systematically considered, the electromyoplis is very fully and clearly dealt with. From his own experience Einhorn believes that a perfect cure of the condition is possible. Nervous affections of the stomach, and the condition of the stomach in diseases of other organs, have chapters specially devoted to

(a) "Diseases of the Stomach: A Text-Book for Practitioners and Students." By Max Einhorn, M.D., professor in Clinical Medicine at the New York Post-Graduate Medical School and Hospital, Visiting Physician to the German Dispensary, Third Revised Edition, pp. xvii and 584, with 74 Illustrations, demy 8vo, price 14s. net. London: Bailliere, Tindall and Cox. 1908.
their consideration. As regards treatment, much valuable help is given by the detailed dietary which the author has reproduced for the benefit of the general practitioner. With reference to the treatment of gastric cancer, he has confined to us it is interesting to note the author's opinion that both hydrochloric acid and pepsin are quite inefficacious; nor does he approve of predigested foods, as these only tend to still further impair the activity and power of the stomach.

As to the pathology of gastric cancer, the author gives a very able review and criticism of this interesting question, finally stating that in all probability one and the same cause is not always the underlying factor in its production. The absence of hydrochloric acid is not regarded as of much significance in the diagnosis of gastric cancer, as this phenomenon is associated with many other conditions, e.g., severe gastric catarrh and achylia gastrica.

This work has been already well received by the profession both in this country and abroad, so that a criticism of its merits would be altogether out of place at this time, but we feel called upon to state that the work has brought much erudition and a wealth of practical experience to bear upon a subject at once difficult and at the same time of intense importance. When in difficulty as to the diagnosis and treatment of a disease, the possession of a comprehensive and trustworthy treatise will not turn to it for help in vain. It is a masterly piece of work, written by one who is thoroughly in touch with his subject.

TUBERCULOSIS. (a)

This excellent manual is based on the author's lectures delivered at the Rush Medical College during the past three years, and contains a clear, concise and fairly comprehensive presentation of the subject in a form which will prove particularly serviceable to the young practitioner. The treatment of the subject is not exhaustive, but a faithful statement of the science of the disease has been attempted, and the practical side of the care and management of those afflicted with the different non-surgical forms of tuberculosis has been emphasised, and measures for the protection of the community and the arrest of the scourge definitely indicated. All phases of the subject receive attention, but the most valuable portions for the practitioner are undoubtedly those dealing with prophylaxis and treatment. The various charts compiled from the United States Census Reports are of particular interest and value, as affording useful guidance in the formation of a trustworthy prognosis.

Dr. Bridge is a strong believer in the advantages of long-sitting and exercises which indicate a method of strangling the chest in order to restrict the action of the affected lung. At the present time, when sanatoria are springing up in all parts, it is to be regretted that more space was not devoted to the consideration of the institutional treatment of tuberculosis.

The work is of convenient size, well arranged, excellently printed, and will serve a good purpose; but its usefulness would have been increased if the author had provided references to the original work of those on whose conclusions much of his teaching is necessarily based.

ATLAS OF HUMAN HISTOLOGY. (b)

This book consists of a somewhat modified translation of Soubota's "Epitome of Human Histology," the special feature of the volume being, of course, its plates. Among the particular merits of these we may notice that most of them are drawn from preparations of the United States Census Reports, for the forehead of much greater value for teaching purposes than the more usual figures taken from the tissues of the lower animals. It is not unusual for a student versed in histology to feel quite at sea when confronted with a section of a human viscous owing to his studies having been entirely restricted to organs made from the organs of such animals as the rat and pig. Again, the idea of giving a general view of an organ under a low power, side by side with more highly magnified figures, is excellent; but it is a matter of regret that this method was not carried out more fully. For example, no complete section of the prostate is represented. On the other hand many of the plates have suffered from a too liberal application of very vivid colours, the effect in many cases being anything but attractive.

Concerning the text there is little to be said, but we believe that the book would be more suited for students if the language employed were a little less technical, and if fewer proper names figured in the descriptions.

Among minor faults we may note that the account of the white cells of the blood is distinctly poor and somewhat confused. The claim that the glands of the stomach are stated to be exactly similar to the chief cells of the cardiac glands—a statement which is repeated from book to book, but which even the nursery examination will show to be false, is quite misleading. That the description of the nerve supply to the muscles of the iris on page 220 is liable to mislead.

In the description of the kidneys no reference is made to Max Bödell's recent and valuable work.

LEGAL MEDICINE. (a)

The second volume of this work has not yet appeared; in the first, the one before us, legal medicine as constituted from toxicology, is made up of the contributions of sixteen gentlemen, all of whom have won recognition in their special departments. The Editors tell us that "with few and wholly unimportant exceptions, the articles comprising the last two volumes have been inserted without change." This absence of editing is not always a gain, especially for the student. Commencing with the most important branch of the subject, we turn to the question of identity. Identity of the living animal, identity of the dead before and after decomposition; and identity of portions of the body. The difficulty of identification is largely due to the fact that the lay public are not the observant of anatomical peculiarities; they have not been trained to observe them. Now medical students in a text-book on forensic medicine should be taught what to observe, and cases in which anatomical peculiarities or pathological lesions have been of importance should be fully told. Photographs are to-day much relied on; all our criminals, when captured, are photographed. Orton, the claimant, was photographed; and the photograph compared with that of Sir Roger Tichborne, showed that the external angles of the butcher's eyes were on a lower level than the internal ones, whereas Sir Roger Tichborne's eye angles were on a level. Again, the butcher's ears were large, thick, prominent; those of Tichborne were just the contrary. The claimant also had a large metacarpal phalangeal article of the right thumb, which is so characteristic of all who commence manual labour early in life. Of these three peculiarities of the claimant the book makes no mention. On the question of identifying of infants little is said, yet we have seen a judge of the Superior Courts stop the Crown Counsel in the prosecution of a case until the identity was proven. The author of "Puddled-Headed Wilson" is conscious of this difficulty, and the plot of his story is made to hinge on it. Foot-prints have their value pointed out, but the remarkable case of the Manchester artisan, who was condemned to death for shooting a policeman, is a very small narrow foot, the shoe of which had a transverse patch,
Fortunately, the man was not hung, and two years after the notorious Palmer stood up to the crime, and demonstrated that the impression of the boot was his. It is not too much to expect such an important case to be noticed. Pathological lesions played an important part in the Wainwright case, where on one occasion, in highly civilized England, a cataract of a burn on one of her knees. We refer to these concrete cases because a medical witness is supposed to be familiar with them. We expected the direct dealing with the question as to the time occupied in decomposition that the Editors, if not the authors, would have recognised that Caspar's standard was out of date. Many things influence the rapidity, or otherwise, of decomposition, witness the recent London animal poisonings and the Moat Farm case. We are not impressed favourably with the book. It reads too much like a compilation and too little like a record of personal experience.

**Lawson on Diseases of the Eye**

The clinical portion of this work is distinctly good, and as such is to be regarded as the best English textbook we have on the subject. It is a pity, however, that this great work should be spoiled by the use of the old-fashioned phrase, "rheumatic iritis," which certainly belong to the dark ages of ophthalmology, and seem to be handed down from generation to generation of writers (not Continental). It is a truism to say that a scientific nomenclature should be founded on a strict pathognomonic basis. The term "rheumatic" nowadays, unless applied to rheumatic fever, or some of its manifestations, is quite meaningless. Most physicians tell us they never see iritis in rheumatic fever!

Again, the term "serous inflammation," as used by pathologists, implies inflammation of a serous membrane, which the iris certainly is not. Would it not be better to call the disease a "toxic irido-cyclitis," whereby we commit ourselves to no definite etiological factor? Decidedly, we know absolutely nothing definite about the cause. Is there any real distinction between the so-called "rheumatic iritis" and the so-called "serous irido-cyclitis"? Mr. Lawson makes no mention of "tuberculous iritis."

Would it not be better for writers to dispense with the old-fashioned phrase, "acute inflammatory glaucoma," or inflammation of what? Is glaucoma an inflammatory disease at all? The acute congestion of the conjunctiva as seen in these cases is no doubt a herald of the condition brought about by the closure of the slit-like holes in the sclerotic through which the aqueous vessels pass, and the channels of the effluent blood stream of the uveal tract being thus blocked, the return blood has to leave chiefly by the anteriorly veined, a circumstance which accounts for the hyperemia of the conjunctiva.

It is a pity that Mr. Arnold Lawson did not get a colleague (Mr. Silcock or Mr. Morton for instance) to read over his article on "Elementary Optics." The definition of refractive index is quite wrong. In the chapter dealing with "General laws Governing all (sic) Lenses," we are informed that "parallel rays of light after passing through the lens are brought to a focus at a spot known as the principal focus." Figs. 13 and 16 are drawn inaccurately. In Fig. 24, M points to the ciliary processes, instead of to the ciliary muscle. Fig. 34 is clumsily drawn, and though the theory of the indirect method is described, no attempt is made to explain the theory of the far more important direct method. Are all the dark-complexioned races negroes (p. 41)? This is a compliment to the 300,000,000 of his race, the highly of an Indian subjects, and hardly calculated to engender the respect and approval of the native medical students who may happen to read this book. Is it a fact that arterial (retinal) pulsation is never seen in health? Sir William Gowers says it is.

Is it correct to say that in hypermetropia there is a diminution of the normal static refraction (p. 61). In ordinary cases, is it not the position of the macula which determines hypermetropia or myopia? The statement (p. 61) that theoretically the correcting lens should theoretically lie in the anterior focal plane of the eye, i.e., 137245 mm. in front of the cornea. Fig. 35 is wrongly drawn. F and F should be of the same size as L. We have felt it necessary to draw attention to these little inaccuracies in the hope of correction in future editions, as a book so excellent in its clinical material should not be marred by errors of so serious a nature.

**Obituary**

Mr. H. G. CROY, F.R.C.S.I.

We regret to announce the death of Mr. Henry Gray Croly, which took place on the 28th ult. Mr. Croly was one of the most notable members of the surgical profession in Dublin. He, a student, was a surgical dresser in the Navy during the Crimean War, and took part in the memorable bombardment of Cronstadt. Having on the completion of the war finished his medical studies, he returned to Dublin. He was appointed a demonstrator of anatomy in the Royal College of Surgeons' School, and became pro-dissector to the late Prof. Morgan. In connection with some other demonstrators he took part in a "gilded class," but after a time his practical nature asserted his discontinuance of private teaching. Having been Resident Surgeon to the City of Dublin Hospital he had little difficulty in securing the appointment of Visiting Surgeon on the occurrence of the first vacancy. He quickly came to the front as a brilliant and successful operator, who kept well abreast with every advance in surgery. He attracted large classes of students to his clinical lectures, which were lucid, didactic, and intelligible. He was one of the first to recognise the value of antisepsis, and the necessity of asepticism. He was zealous in the pursuit of surgery, and had the gift of exciting enthusiasm in his pupils. He excelled in such operations as amputations, lithotomies, and the radical operation for hernia, all of which found him confident and self-reliant in their performance and dexterous in their technique. He was, however, too long in practice when he felt it to be recognised as a proceeding expected of hospital surgeons to acquire the facility in that class of operation which characterises the work of a Murphy or a Senn. Mr. Croly was one of the links that bound the rising generation of surgeons with those of the past, and the many and oft-repeated warnings of the older men against interference with serious membranes continued to influence, although unconsciously, his acts. Forty years ago he took the F.R.C.S.I., and during all those years he has borne an active part in all that concerned his profession. He was a frequent and valued contributor to the proceedings of the old surgical and pathological societies. At the Royal Academy of Medicine he was one of the most constant attendants, and his papers are to be found in every volume of the "Transactions." His professional brethren recognised his ability by electing him time after time to the Board of Examiners of the College; to the Council of the College; and finally by electing him President of the Royal College of Surgeons for two years in succession.

**Professor Karl Maydl**

We have to record the untimely death of Prof. Maydl, who so worthily occupied the Chair of Surgery in the Vienna University, and who has just passed away in his fifty-second year. Albert remarked at the death of his colleague, Dittl, that the life of a surgeon was brief, and considering all he thought Dittl had reached a ripe age, sixty years, as a surgeon. It would seem from the late series of deaths that this assertion is correct, at any rate as far as Vienna is
concerned. Albert himself soon passed away after this remark, followed by Gussenbauer and Nikoladoni. Bilbroth, whose European fame attracted so many pupils, also passed away in the intellectual prime of life, leaving Maydol, very suddenly.

Maydol was born 1851, in the town of Innsbruck, where he was educated and became Albert’s assistant, following him to Vienna in 1881. He was admitted to the list of academic teachers in 1864. In 1866 he was appointed to the Polyclinic department of surgery, and though the beds were few his observations testified to a vast amount of work. In 1888 he was made extraordinary Professor of the University, and in 1891 ordinary Professor of Surgery, at Prague, where he came to Vienna on the death of his early teacher, Prof. Albert.

As an operator, he was of the first order, well versed in every mode of treatment; as a clinician his diagnosis had no rival.

His literary works are numerous. Among his earliest efforts were those on the correction of “Tendon Laxation,” such as that of the peroneus, which he considered pathological and a piece of peritonitis to which the tendon was attached. This procedure was subsequently extended to muscles. In the following year he turned his attention to the injection of saline solution in cases of rheumatism, which were conducted with stricter radical treatment of hernia, gastrostomy, jejuno-stomy, &c. He also contributed a number of papers on echinococcus of the pleura, cysticercus cerebri, and so forth. His loss is mourned as a serious one for the University and for science.

WM. TOCHER SCOTT, M.A., M.B., C.M. (Aberd.)
Dr. W. T. Scott, of Slatebridge, who died early last week at the early age of 36 years, was a native of Aberdeen. He was honorary medical officer at the Ashton District Infirmary, and a month ago, while performing an operation in that institution, he accidentally scratched the middle finger of his right hand with the point of the knife. Symptoms of pyrexia followed, to which, in spite of every effort, he ultimately succumbed. At the inquest the Coroner remarked that Dr. Scott died at the post of duty, and expressed his own and the jury’s sympathy with the bereaved relatives. A verdict to the effect that death was due to blood poisoning was returned.

WILLIAM SMILES, M.D.Ed., M.R.C.S.
The death is announced of Dr. William Smiles, who formerly practised in Bedford Square, W.C., who died on Wednesday, at his residence, St. Martha’s Lodge, near eighty-seven. Educated at Edinburgh, where he took his M.D. degree as long ago as 1839, Dr. Smiles was admitted a member of the Royal College of Surgeons of England in 1861. He was for many years surgeon to the Government Prisons at Coldbath Fields and Clerkenwell, and Physician to the St. Pancras Royal General Dispensary. He was a Fellow and formerly Vice-President and Secretary of the Medical Society of London, and a Corresponding Fellow of the Madrid Academy of Surgeons. The funeral took place at Highgate Old Cemetery on Monday last.

DR. CHARLES HATHAWAY, OF ST. LEONARDS.
The death occurred on Saturday, at his residence, St. Leonards-on-Sea, of this gentleman, at the ripe age of eighty-six. He was educated at King Edward’s School, Sherborne, and, after some years spent at St. Thomas’s and Guy’s Hospitals, went to India as assistant surgeon in the East India Company’s service. After the mutiny he was employed in the Field Hospital, he was appointed Civil Surgeon at Lahore. During the Mutiny he slept at the Central Gaol, where two thousand long-term and life convicts were immured. In 1843 Dr. Hathaway was appointed Inspector-General of Prisons in the Lahore Province; and in 1862 the military authorities, on a severe outbreak of cholera amongst the European troops, appointed him to the post of Sanitary Commissioner.

He was appointed Private Secretary to the Governor-General of India (Lord Lawrence) in 1863, and finally left the Service in 1866. St. Thomas’s Hospital, London, House Appointments.
The following gentlemen have been selected as house officers from yesterday, Sept. 1st:—

- Ophthalmic House Surgeon: (Senior) A. C. Hudson, M.A., M.B., B.Ch.Cantab.

International Congress of Hygiene.

It is now twenty-five years ago since the first International Congress of Hygiene and Demography assembled at Brussels, and this year the eleventh meeting of the world’s health and sanitation experts is to be held in the same city, commencing on 12th September. The intervening gatherings have taken place in Paris (1878 and 1890), Turin, Geneva, The Hague, Vienna, London, Buda-Pesth, and Madrid. This year some fifteen hundred delegates are expected at Brussels. The King of the Belgians is patron of the Congress, and the acting president is Mons. E. Beco, Secretary-General of the Ministry of Agriculture, and Chief Director of the Sanitary Services of the Kingdom of Belgium.

Death Under Chloroform.

An inquest was held last week at Bolton on the body of a lad, aged 14, who died under chloroform at the local infirmary while undergoing an operation for the removal of adenoids. The usual verdict was returned. A similar catastrophe, under identical circumstances, is reported from Huddersfield, where a lad, aged 9, suddenly died after the removal of enlarged tonsils and adenoids. Death was attributed to heart disease, and at the inquest a verdict was returned in accordance with the medical evidence.

Indian Medical Service.

Dublin Death Rate.

The deaths registered during the week ending Saturday, August 32, 1903, in the Dublin registration area represent an annual death-rate of 233 in every 1,000 of the population. Thirty-five deaths resulted from tuberculous disease, 5 deaths from diseases of the nervous system, 22 deaths from diseases of the circulatory system, and 23 from diseases of the respiratory system; 40 infants died during the week, of whom 36 were under one year old. In 6 instances the cause of death was uncertain, there having been no medical attendant during the last illness.
NOTICES TO CORRESPONDENTS. 

ORDINARY ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, by giving notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

THE PSYCHOLOGY OF OPTIMISM.
An optimist is a person who enjoys the stomach-ache because it is so nice after it is over.—New York Post.

And (throwing grammar to the winds) a pessimist is a person who enjoys his stomach-ache while he's got it.

DIETING MOSQUITOS.
They've discovered a fine, hair-like weapon which is said to be certain death for the mosquito that eats it. But the average mosquito seems to prefer some other diet. It will be found very flattering to squint with a visiting mosquito at London's finest line of clothes, since he frowns the bloodthirsty intentions and dies off a worm instead.

M. E. — The strength of the solution of picric acid for application to burns is from one half to one per cent. It appears to be a much more efficacious, as well as a more cleanly application than the old-fashioned salubrity.

A CHEAP EAR AND NOSE SPECULUM.
A correspondent, referring to the fact that a very serviceable speculum for ear and nose work is provided by the ordinary nickel pencil point protector, prefers the model which is open at the smaller end, although the closed form can readily be "filled open.

Carried on the pencil is the well-known pocket, has the advantage of being always ready to hand.

GAS FIRE.
A correspondent who has made the subject a special study, sends us the following note:—It would be well that those who are now strongly supporting the use of gas fires instead of coal for domestic purposes, should carefully study the dangers to which we are subjected if we do not thoroughly understand them. In an article on "Gas Fires and Their Hazards," published in the "Gazette" of 1890, Mr. W. W. G. Dix was quoted, and it is surprising that stoves of various kinds are supplied to the public which require no chimney to carry off the poisonous products of combustion. It is not Asphyxial or Carbonic Monoxide, but Carbonic Acid gas which is most to be feared. A coal fire has the advantage that if the products of combustion are not carried off, the smoke gives evidence by coming into the room. Carbonic Acid gas has no such proof of its presence, and as most gas stoves are not provided with proper chimneys, it is not healthy to use them. If we are going to use gas instead of coal, a very different system must be employed to that of our open grates, in which a great loss of heat is required to work the draught up to give it space to.

Dr. A. D. — The "facts" have no possible medical bearing, so that we are not likely to give space to.

Sir, S. Wilson, The Scotch and Irish schools open somewhat later than those in England. Full dates and particulars of all will be given in our Educational Notes for September 16th.

Dr. H. W. — We have deferred dealing with the master at your request, in order to take a little time for reflection.

P. R. G. — The gentlemen referred to leaway on his annual holiday. Your communication shall be handed to him on his return.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, SEPTEMBER 2nd.
POSTGRADUATE COLLEGE (West London Hospital, Hamsworth Road, W.)—3.30 p.m. Dr. Robinson: Bacteriology in Gynaecology.

THURSDAY, SEPTEMBER 3rd.
POSTGRADUATE COLLEGE (West London Hospital, Hamsworth Road, W.)—6 p.m. Mr. Edwards: Rectal Fistula. (Lecture Room.)

FRIDAY, SEPTEMBER 4th.
POSTGRADUATE COLLEGE (West London Hospital, Hamsworth Road, W.)—3.30 p.m. Dr. Taylor: Medical Cases. (Medical Ward.)

Appointments.

JAMES, WALTER BRYDON, M.R.C.S., L.R.C.P. Lond., Senior Medical Officer for the whole of the Midland and South Eastern India, found in connection with the Bissamput Iron and Coal Works. James has been appointed to the responsible posts at the Midlands.

JOHN WATTS, M.D., F.R.C.S., F.R.C.P., Lond., House Physician and Surgeon to the Aberdeen Royal Infirmary.

MAYRAND, JAMES D. M., Surgeon-Certifying Surgeon under the Factory Act for the Camborne Iron and Coal Works.

SANDERS, ERNEST B. D., Certifying Surgeon under the Factory Act for the Silverton District of the County of Devon.

SCOTT, W. T., M. R. E. CANTAH, House Physician to the Royal Berkshire Hospital, Reading.

Vacancies.

Cumberland Infirmary, Carlisle.—Resident Medical Officer, Salary £100 per annum, with board, lodging, and washing. Applications to J. G. Howitt, Secretary.

Down District Lunatic Asylum, Downpatrick. Junior Male Assistant Medical Officer, Salary £100 per annum, with board, washing, and washing. Applications to the Resident Superintendant.

Metropolitan Hospital.—Casualty Officer and Pathologist and Registrar. Salary £150 per annum, Applications to Charles H. Byes, West Ham Hospital, Stratford, E. Junior House Surgeon, Salary £75 per annum, with board, residence, &c. Applications immediately to the Secretary.

Newcastle and District General Infirmary.—House Surgeon, Salary £150 per annum, with board, residence, &c. Applications immediately to Charles A. W. B. M., Secretary, Inverness, Downpatrick. The Royal Infirmary, Sheffield. Junior Assistant, House Surgeon, Salary £70 per annum, with board, lodging, and washing. Applications to George Henry Day, Secretary.

Chesterfield and North Derbyshire Hospital and Dispensary.—Resident House Physician and Surgeon. Salary £270 per year, with board, apartments, and laundry. Applications to the Secretary.

County Asylum, Chesham, near Chesham, Kent.—Third Assistant Medical Officer. Salary £140, with quarters, attendance, and washing. Applications to Medical Superintendent.

Brighton, Hove, and Preston Dispensary.—House Surgeon. Salary £150 (with extra £5 to provide Lunen Tenens during holidays), furnished rooms, shoe, gas, lighting, and washing, at the discretion of the Committee. Applications to Hon. Secretary, 118, Queen's Road, Brighton.

Esher and Cobham General Hospital and Dispensary.—House Surgeon, Salary £150 per annum, with board, washing, and residence in the hospital premises. Applications to G. W. J. Smith, Secretary.

Ballinlough Union.—Medical Officer. Salary £100 per annum together with Registration and Vocational Fees; also to act as Medical Officer of Health, at a salary of £100 per annum. No application to be sent before September 15th. For address, see advertisement in this number.

Applications to the Secretary.

Lunen Tenens for Dispensary District and Private Practice. Terms £5 to £6 per week all paid. Address Dr. MacDermott, Ballyhaderin.

Births.

MAY.—On August 28th at 81, St. Davy's Road, the wife of Charles Graham Meade, L.S.A., of a daughter.

SQUIRES.—On August 27th at the Paddington Infirmary, the wife of Maurice F. Squires, of a son.

TRUMANS.—On August 27th, at 25, High Street, Warwick, the wife of Hubert Trumans, M.B., of a son.

Marriages.

SAPES.—DUNLEY.—On August 26th, at St. Mark's North Audley Street, Major Herbert L. Sapse, third son of the late Capt. W. J. W., and Winifred Agnes, eldest daughter of J. H. Pugh, M.R.C.S. Eng., of St. George's, to Susanna Dunley, eldest daughter of the late Mr. and Mrs. of Dunley House, Rugby.

WALLAS.—HONORS.—On August 27th, at Matthew's Bay, Wivenhoe, Neville Courtenay, fifth son of Dr. E. D. Walls, Leiston, Suffolk, to Frances Alice, elder daughter of Mr. and Mrs. Wallas, of the late James Wallis Hobson, Bombay Staff Corps.

WILSON.—HARE.—On August 27th, at St. Michael's Church, Betchworth, Surrey, Francis Kenneth Wilson, M.B., of Walsingham, Suffolk, and Miss Emma, eldest daughter of Bernard F. Harris, of Betchworth, Surrey.

Deaths.

BROOKES.—On August 26th, at East Adale, widow of the late Surgeon Major J. P. Brougman, M.D., J.P., of Inverness, aged 70.

BROWN.—On August 26th, at Weston-super-Mare, Julia Eliza, youngest and last surviving daughter of the late Hayward Brown, M.D., of Painewick, aged 76.

CHASE.—On August 26th, at 5 Archway Road, No. 7, Melbourne Square, Dublin, Henry Grey Chase, F.R.C.S., of Inverness, aged 70.

FLETCHER.—On August 26th, at King's Heath, Birmingham, Emily, widow of the late Edwin James, Esq., M.R.C.S., aged 58 years.

FRANKLIN.—On August 26th, at 41, Deansgate, Manchester, Mrs. C. H. M. of High Minto, M.R.C.S., of Woolwich, and only daughter of Sydney Gedge, Esq., of Milham Surrey.

SMILES.—On August 30th, at St. Martha's Lodge, near Guildford, William Smiles, M.D., aged 87, formerly of 44, Bedford Square, London.
Original Communications.

THE VALUE OF ARTHROTOMY IN THE TREATMENT OF CERTAIN JOINT LESIONS. (a)

By P. LOCKHART MUMMY, B.C.Cantab., F.R.C.S.Eng.,
Demonstrator of Operative Surgery, St. George's Hospital.

The treatment of joint lesions by operative procedures has advanced very considerably within quite recent years, and with it has advanced our knowledge of the causation and pathology of many previously obscure joint affections, for it was not until surgeons began to operate upon these cases that anything was known about their pathology, except in the more advanced stages, when, owing to the death of the patient, an opportunity was afforded of examining the joint. A great many cases have been published within the last few years of what, for want of a better term, I may call subacute septic joint lesions, following, or occurring at the same time as, definite specific infections of other parts—cases, for instance, where a joint has become affected during or shortly after an attack of influenza, scarlet fever, measles, pneumonia, &c., or has followed some septic lesion such as whitlow, or even oral sepsis, and in which the presence of the organism or organisms causing the original disease has been demonstrated in the joint fluid.

And it seems more probable that many of the subacute and chronic joint lesions which have hitherto been collectively classed under the term chronic rheumatism, or rheumatoid arthritis, are in reality pyaemic in origin, and are directly comparable with gonorrheal arthritis, a disease which itself was classed as a form of rheumatism not so very long ago.

It would appear that whenever a patient is the subject of a specific microbial infection, in the course of which organisms obtain an entrance to, and are able to circulate in, the blood stream, an arthritis may develop.

The factors which determine whether or not the organisms shall become arrested and set up inflammation in a joint, rather than in any other tissue, are still somewhat uncertain. The fineness of the capillaries in the synovial membrane is certainly an important factor, and the importance of traumatism in the localisation of a microbial blood infection has long been recognised. Traumatism acts by causing blood stasis, and so allowing the organisms, which previously were circulating in the blood stream, to come to rest, liberate toxins and set up the phenomena of inflammation. It has been experimentally demonstrated that septic organisms circulating in the blood of a healthy animal are quite harmless and rapidly disappear from the blood without causing any harmful results, providing always that no foreign matter is circulating in the blood at the same time, which, by blocking up the smaller capillaries might allow of the arrest of the organisms. Directly foreign particles, such as sterilised cinnabar seeds, &c., are introduced into the blood stream with the organisms, or a local traumatism such as a bruise is caused, septic symptoms occur.

In this connection it is interesting to notice that Drs. Poynton and Paine have recently demonstrated the fact that an arthritis of a subacute or chronic nature, closely allied in pathological appearances to the chronic arthritis of human beings, can be produced in rabbits by the intra-venous injection of a diplococcus. (Lancet, vol. i., 1902.) This shows that even without any previous traumatism or disease being present in a joint, organisms circulating in the blood stream may become localised there and set up inflammation. As to whether the arthritis so caused will be an acute or chronic one must depend upon the suitability of the joint tissues for the growth of the particular-organism present, and upon the pathogenic properties and degree of virulence of the organisms causing the infection.

The type of joint lesion with which I particularly propose to deal in this paper is the acute and subacute septic arthritis which follows infection of the joint from the blood—and which has sometimes been called pyaemic arthritis—but which is not part of a general pyaemia.

There is probably always in these septic or infective joint lesions a primary septic focus in some other part of the body, but this may be so apparently insignificant as to escape notice, or may have cleared up before attention is directed to the condition of the joint.

Acute Septic Arthritis.

This is not common, except as the result of direct infection of a joint from a wound, but occasionally occurs by infection from the blood without being part of a general pyaemia. It may occur in a person who is much run down in health, or during the course of some acute fever. The following is a good illustration of such a case:—
H. L., an Army teacher, rt. 21, had got very much run down in health. As the result of some slight abrasion he developed a pustule on the first finger of his left hand. Five days after this, while sitting in the park he felt a sudden pain in his left ankle; he managed to get home, and then sent for a doctor, who, considering the case to be one of acute rheumatism, treated him with slight bleeding and some morphia. The condition of his ankle, however, instead of improving, rapidly got worse, and at the end of four days he was admitted to the hospital. On admission, his temperature was 102°F., and he was very ill; the pustule on the finger had, by this time, almost healed. The left ankle-joint was much inflamed and swollen, and obviously contained pus; it was opened freely by a possible incision anteriorly and treated with a continuous water bath. It did not improve, however, and a week later was again opened up. The patient's condition, in spite of this, did not improve, and he developed symptoms of septicämia, and became extremely ill. Three weeks after admission the leg was amputated at the ankle-joint for infection. After this he gradually recovered, and left the hospital for Margate a month later.

In this case there was no history of any traumatism or previous disease of the joint, and at no time were there any symptoms of a general pyæmia. The primary source of infection seemed to be the primary ulcer on the finger, and it is certain that if the joint could have been opened earlier the limb would have been saved.

In dealing with acute septic arthritis, everything depends upon early incision and relief of tension in the joint, before there has been time for advanced secondary changes to occur, and before the synovial membrane has been seriously and perhaps irreparably injured.

Whenever there are indications of acute septic infection of a joint, no time should be wasted, but the joint should be at once opened. It is true that if treated with hot fomentations, rest, &c., a certain number of these joint lesions will get well without operation, but the risk of waiting is much greater than that of early incision, and the chance is not worth considering. The joint should be thoroughly washed out with hot water and any adherent lymph, &c., removed if possible. Washing out the joint removes the greater part of the infective material, relieves the tension, and allows the synovial membrane to recover itself, and so deal effectually with any infective material left. The joint should, in fact, be treated in exactly the same way as is the abdominal cavity under similar conditions. The importance of early operation in septic lesions of the peritoneum has been much accentuated of late, and all that has been said in respect of early operation in abdominal lesions applies with equal, if not with greater, force in the case of septic joint lesions.

Everything, in fact, depends upon early and prompt incision into the joint during the early stages of the inflammation. An acute septic arthritis is a most serious condition, and the results are most grave. I am afraid that it is too often thought that the condition is of so grave a nature that the best that can be expected, when a patient develops a septic joint, either as the result of an injury or in the course of some general infection, is a stiff joint. I am convinced that this is not the case, and that if only the joint can be opened, irrigated and drained quite early the results would be much more favourable.

After the joint has been washed out, it is usually advisable in the acute cases to insert a drain for a time. The question of draining joints is a very difficult one. It is practically impossible to establish efficient drainage in most of the joints owing to the close contact of the bones, and the thinness and pouting of the synovial membrane. The ordinary method of draining the knee-joint by passing a tube from side to side of the joint beneath the patella, for instance, is quite insufficient, as the tube is usually so nipped between the patella and femur that it cannot act as a proper drain. Also pus collects in the posterior part of the joint around the crucial ligaments and does not escape by the tube.

In the case of the knee-joint, in order that drainage shall be efficient it is necessary to make the window either in the prone position or in the lateral position with the knee turned well on to the side, so as to make the site of the incision the lowest part of the joint cavity. As a rule the leg is put on a box splint with the posterior and the thigh and pouting of the synovial membrane. The ordinary method of draining the joint by passing a tube from side to side of the joint beneathcess. As a rule the leg is put on a box splint with the posterior and the thigh and pouting of the synovial membrane. The ordinary method of draining the joint by passing a tube from side to side of the joint beneath the patella, for instance, is quite insufficient, as the tube is usually so nipped between the patella and femur that it cannot act as a proper drain. Also pus collects in the posterior part of the joint around the crucial ligaments and does not escape by the tube.

In bad cases of septic arthritis of the knee, where it is difficult to obtain proper drainage, or when after having drained the joint in the usual way the symptoms do not abate, a very good plan is to freely expose the joint by dividing the patella transversely. If the joint is then flexed the synovial membrane can be very thoroughly exposed and dealt with, the patella can be subsequently wired together after providing for proper drainage. I do not think that there is any necessity to open the joint from behind in the popliteal space, if, after the operation, the joint is kept in such a position that the lateral incision is the lowest part of the joint. The best plan is to place the knee flexed upon a pillow, and not use a splint.

The slight amount of movement that may occur in the joint as the result of not using splints is of advantage in assisting the drainage. By allowing the joint surfaces to move on each other it prevents the pus or fluid from being shut off by the coaptation of the different parts of the joint.

Subacute and Chronic Septic Arthritis.

In many of the cases of subacute septic arthritis, such as are seen after pregnancy, when there has been some septic trouble in the genital tract; after many of the acute fevers, measles, scarlet fever, pneumonia, &c., and after gonorrhœa, opening the joint, washing it out, and closing it again gives excellent results. If treated by rest, lotions, &c., these cases show a marked tendency to the formation of adhesions in the joint, or to recurring attacks of synovitis with effusion from slight causes, and a more or less crippled joint is often the result. And even when recovery does take place without operation, the time during which the patient is incapacitated is often protracted.

In most of these cases the onset of the joint affection is more or less rapid, and follows some slight trauma. The joint becomes painful and
hot, and there is considerable effusion into the synovial membrane. The skin over the joint is often red, and there is tenderness on palpation. These symptoms are usually accompanied by rise of temperature, especially at first. Many of the cases are at first mistaken for acute rheumatism, but the characteristic signs of that disease are absent, and the condition does not react to salicylates.

If in a case the joint is opened, all adherent lymph removed from the synovial membrane, the cavity of the joint washed out and the wound closed, the symptoms usually rapidly subside, and a useful joint is obtained in a short time.

Many of these cases will recover without surgical interference, but arthroplasty greatly reduces the time during which the patient is incapacitated, and prevents the synovial membrane from being damaged.

Arthroplasty is particularly indicated when the joint resists treatment by other means, the pain and effusion do not subside, and the temperature shows a tendency to rise in the evening.

In gonorrhoeal arthritis, when there is much effusion in the joint and a good deal of local inflammation, arthroplasty is certainly the best method of treatment, and if properly carried out gives excellent results. In these cases especially there is a marked tendency to the formation of adhesions, and recovery by other methods of treatment is very slow and tedious. In gonorrhoeal and acute arthritis results are seen when the joint or joints are opened early, before there has been time for the joint tissues to become changed and altered from the inflammation, and before adhesions have formed. But even in old standing cases where one or several joints have been affected for many months, and there has been no improvement in the local condition, arthroplasty and irrigation of the joint or joints will often effect a cure in the most astonishing way.

In the more chronic cases of septic joint a course of massage and movement should first be given a trial, but when the joint resists all treatment and remains painful and swollen, or improves for a time only to relapse again as soon as the patient begins to use it, arthroplasty should be performed and the joint irrigated.

There is another class of joint lesions in the treatment of which I think arthroplasty might be used more often than it is at present. I refer to those cases where, as the result of some previous injury or as the result of disease, firm fibrous adhesions have formed in a joint, resulting in fibrous ankylosis.

Opening the joint and dividing the toughest bands with a knife is often better treatment than attempting to break down the adhesions by force. In some of the old standing cases of this nature in the knee-joint, it is impossible to break down the adhesions by forcibly bending the joint under an anaesthetic without very considerable violence is used. And there have been several cases where, as the result of such violence, the patella has been fractured, or the shafts of the bones broken above or below the joint.

When it is found that the adhesions are of this nature, and that in order to rupture them great force will have to be used, it is better to open the joint by an incision on one side of the patella, and then with a knife divide the resisting bands of adhesion, before proceeding to flex the knee.

Again, in those cases where, as the result of injury, haemorrhage has occurred into the joint, and the synovial membrane is distended with blood, arthroplasty is the best method of treatment. After the removal of the blood clot, the joint rapidly recovers, and many weeks of tedious convalescence can often be saved to the patient, not to speak of the relief of pain which results, and the tendency to subsequent trouble in the joint which is prevented by the early removal of the clot.

With regard to the method of performing the operation. In the case of the knee-joint I think the best incision is one about one and a half to two inches long on the outer side of the joint, halfway between the edge of the patella and the external tuberosity of the femur. If this incision does not give sufficient exposure it may be supplemented by another on the other side of the joint. A vertical incision is the best, as it does not involve the division of any of the important ligamentous structures of the joint, and a minimal portion of the subsequent scar will be over the bone—a very important point. When a transverse incision is made the seat often becomes adherent to the head of the tibia and to the base of the patella, and the pain afterwards when the joint is moved. In the ankle-joint, I think the best incision is a vertical one just behind the external malleolus.

Through the incision the fluid in the joint can be evacuated, and some of the latter should always be kept for bacteriological examination. The joint should be thoroughly washed out with an irrigator, and sterilised hot water or saline solution until the interior is quite clean, special care being taken to wash out all the pouches and pockets in which pus or infective fluid has probably collected. Any adherent lymph, &c., should be carefully removed at the same time. There is very little object in using antiseptic solutions to wash out the joint, as they cannot destroy all the organisms present, and they injure the delicate synovial membrane, on the power of which to get rid of any infective material left in the joint tissues the success of the operation largely depends.

After the joint has been rendered as clean and as free from lymph as is possible it should be dried out with aseptic sponges, and then the edges of the wound brought together with fish-gut sutures.

In many of the cases when the operation has been performed early, and there is no actual pus in the joint, but only a thin sero-purulent fluid, there is often no necessity to put in a drain, and after the joint has been washed out it can be closed again.

After the dressings have been put on, firm pressure should be applied over the joint by thick layers of cotton wool held in place with bandages so as to obliterate as far as possible the joint cavity, and prevent the re-accumulation of fluid in it. The after-treatment of these cases is of the utmost importance, the patient should be kept in bed, the joint should be moved daily, commencing on the day after the operation. The range of movement that is obtainable is at first slight, but should be increased daily until full movement is obtained in all directions. Voluntary movement is preferable to passive movement, and after the first few days the patient should be encouraged to move the joint as much as possible for himself. After the wound has healed a course of massage is often advisable, especially in the more chronic cases,
where the muscles moving the joint have become wasted from non-use.

This operation is a simple one, and is practically free from risk—the only danger attending it is that of sepsis, and it ought not to be a difficult matter to prevent this if proper care is exercised.

The most rigid aseptic precautions must, of course, be taken in opening any joint, as the results of sepsis in a joint are particularly unfortunate. There ought, however, to be no difficulty in securing absolute asepsis during the operation, and this risk should be a negligible quantity.

There is one small point in the operation which is, I think, of some importance; that is, to make certain before closing the joint that all bleeding has been stopped, and that there is no blood in the synovial cavity.

As regards the relative merits of aspirating the joint and arthroscopy, aspiration has little to recommend it, the risk of sepsis is quite as great, and the joint cannot be properly washed out through a trocar; also in a subacute septic joint there is always always a certain amount of adherent lymph which it is most important to remove, and which will not come away through the trocar.

The more general recognition of the value of arthroscopy in the treatment of many joint affections will undoubtedly lead to great advances in the surgery of joint lesions, and it is to be hoped that the time is not far distant when it will be the routine practice in all the more severe cases.

VARIETIES IN INDIGESTION
AND THEIR CORRELATIONS,
EUROPEAN AND EAST INDIAN.

By WILLIAM H. PEARSE, M.D.Ed.,
Senior Physician Plymouth Public Dispensary.

I do not know of any more fascinating mental exercise than that of the differential diagnosis of the varying symptoms, and the discovery of the true path or path, in so complex a biological or pathological field, and a fortiori the path or paths of right treatment, than is presented by the numerous cases of so-called "Indigestion," which are seen in the out-patient room of a Public Dispensary.

We there see the earliest deviations of function and process, and have opened to our view the widest and most intimate and delicate correlations of the functions of the system; we are carried into a view of disease far more profound than if our field of observation were mainly confined to the more final stages of nomenclatured disease.

I have been much impressed by the phenomena of the varied slight deviations of many functions, which, often for many years, in phthisis, precede the actual lung invasion; a hardly less variety of phenomena and disturbed correlations belong to what we familiarly but vaguely call Indigestion.

Bacon tells us that it is "necessary . . . to imitate the wisdom of the mathematicians, in setting down in the very beginning the definition of our words and terms, that others may not be a difficulty in understanding them, . . . for it cometh to pass, for want of this, that we are sure to end there where we ought to have begun, which is in questions and differences about words." It is obvious that the combined learning and wisdom of the editors of Dr. Murray's "English Dictionary on Historical Principles," aided by the learned editors of the great "Medical Dictionary" of the London Medical Society, could not give us a definition of the word Indigestion.

The digestion and assimilation of crude food to the activities of the bioplasm of a living animal involve the cell-activities of the whole system; in some of the lower animals—the Foraminifer—the food is just as it comes out, its food is still digested, and in any and all parts of the creature's central tube; in other words, the digestive organs and powers are not yet differentiated, but remain diffuse in the contents of the animal. In our systems, though the digestive organs are so greatly differentiated, not the less the "energy" and "motions" which make for digestion and assimilation are diffused in the system generally, and are in every cell. One knows how mental emotion—of joy, fear, thought, &c.—may suspend the desire for food and arrest its digestion; we ought to remember that such mental digestion is not a "thing apart" from other forms of digestion, but has absolute biological correlation and continuity with the processes of digestion and assimilation, and with many other functions, both vital-physical and psychical. I make these remarks because I have long seen a tendency to narrow down our conceptions and practice to lines and points of "specialism," until, indeed, the mind seems incapable of seeing and grasping any general just wide view of generalisation. Such I would further realise Bacon's Aphorism: "He who is not practised in doubting, but forward in asserting, . . . is only fitted to mix and confound things with words, . . . but not to interpret the works of Nature."

The types or varieties of Indigestion which have been depicted occurred amongst the hard-working, hard-living industrious poor, and chiefly among women. The neuroses of such women are apt to show, in the unmarried, during the years of the active evolution of the sexual system; and in older women, coincident with and following the immense strain of their child-bearing years. Such a field of observation is one of great value in biology and pathology, in that we get near to primitive Nature. The phenomena or symptoms are in nature orderly continuity of reversion of biological process and function, e.g., the neuritic indigestion of young women correlates with irregular menstrual function, with sluggish action of the prime vitæ, with anaemia, with sluggishness, with some altered or excited mental development. The whole of such a series of disturbed processes forms part of one whole, of one widely correlated reciprocating general condition or "reversion." We must, in viewing such widely correlating disturbed functions, carefully guard ourselves from resting in single "causes."

I am simply an observer and practitioner dealing with the relief of patients; but it should be remembered that every point in the most "simple" cases is part of an absolutely infinite continuity of arrest and yet little-known "energies" and "movements" of the "energies" of the ultimate motions, of the physiology and of the therapeutics. We are, however, in Medicine the happy inheritors of the experience of mankind, and such experience, though not exact in a modern scientific sense, holds the wisdom of the ages, and if rightly followed will often put us on the right path.
was a bright country girl, fully grown for her age, but with a brightness and grace of mind and conduct of a spirited girl of twelve. She had suffered from dysentery once only, six months ago. For six months she had been under treatment for pain at the epigastrium and across the abdomen after taking food; she had regularly and daily been passed her food; her vomit was sour or bitter; the pain at the epigastrium lasted all day; was not covstive or flatulent. She had for the six months been very much kept on a milk diet, sage and rice puddings, &c., but without benefit to her case. It was obvious that her medical attendant in the country had acted with prudence and wisdom in ordering such a diet; gastric ulcer or its premonitory symptoms might have been excluded from such a diet. But what was my position? Here was a being in process of growth or evolution, the great functions of womanhood bursting into bud and objective existence, the "silent operations" of Nature in full activity. What could I justly conclude? The girl's bright, laughing and happy manner influenced me in thinking that there was no actual ulcer or objective disease of the stomach. She was in the hovering equilibrium of great processes—vital-physical and psychical—evolving within her system. I thus judged the case to be a Neurosis. "What would you like to eat?" I asked. "Cold meat," she replied. "And with a potato boiled in it, a sort of home-picked onion?" added. She exclaimed with delight. "Oh, yes!" I told her to take such food, and to bring me a big bunch of primroses when she, after a week, came back. I prescribed Acid. Muriat. dil., min. xii., Liq. Glycer. pep., &c., to take according to her want. In two days she began the new diet and treatment all pain ceased and has not returned. Weck after week she came back with joy, bringing me great bunches of primroses of her own gathering. In eight weeks the menses returned. I assume that the change of diet to what she specially desired was a right treatment, but I also think that the mental therapeutic" of wandering in the lanes for an hour every day, joyously entering into her primrose gathering, was a most essential part of the treatment.

In a very great number of such cases, both with Europeans and Natives of India, I have found the greatest good from a fuller diet, and especially from a watchful compliance with the patient's desires. I cite this case as suggestive of broad principles, and not as a fixed rule of practice. To learn the right path we must come with a good deal of the spirit of "submision" and a sense of our own ignorance! I have on many former occasions published evidence of the great importance of a judicious compliance with patients' desire for special foods. No rule can be given, but the repeated beseeching for "unorthodox food" should never be treated lightly. I have been deeply impressed with this, not only with Europeans, but also with the Natives of India. Social and professional orthodoxy has its value in our transitional state of civilization, but the courageous and wise practitioner may often effect a startling result by a vulgar unorthodox idea and practice.

Over forty years ago, when I was in charge of Natives of India, I was told beseech for lime-juice and tamarind. Not only would the relatively healthy so beseech, but also those suffering from chronic dysentery diarrhea. Their importunity was extreme. I began with great caution, keeping records of my practice. The people changed more and more. "Aur do, Sahib." ("Give me more, Sir!"")

I found that the practice was of the greatest value. It seemed startling to give people who had extensive ulceration of the big gut "acid fruits," but the voice of Nature showed the true path. The systems of the anemic, for ages under-fed, semi-scorbutic Natives demanded the "acid fruits," the onion, the aromatics, and a full vegetarian diet. Similarly, the Natives of Bengal, Orissa, and Eastern India eating people, showed a great liking for the Chupatti in preference to rice. Here was a people whose natural and prevailing disease was ulceration of the big gut, craving for toughed food. I sent Chupatti, and restoring their health under its use I always saw that every Native had a supply of onions, salt, and chilies. The Native can be trusted in matters of diet, and more so in his use of onions, since he has had them for centuries. The onion of India is old and wise, based on the "historic past." One would see the Native, at odd times, eating a little raw onion (the allyl molecule) with salt, and a tiny piece of red pepper. Such a practice, I cannot doubt, was good for the system. Nevertheless, the use of various drugs, of opium especially, in his diarrhoea and dysenteric discharge, there was a greater method than that of drugs, viz., a just grasp of the historic and technological modes of the people—let them have lost my usefulness and grasp of true method had I confined my pathology to a nosological term and definition—

Dysenteric diarrhoea, an extensive ulceration of the muscular membrane of the bowel, is so ingrained and conditioned and pathology were widely "general," and in our present state of ignorance of the depths of pathology we have to seek much guidance from the habits and instincts of the races whom we treat.

The desire for and use of Aromatic Seeds—the Benzene molecule—by the Natives of India should strongly impress us. The evolution of Cholera in India under a very great variety of changes—changes of season, of weather, of place, of emotion, of food and drink, &c., all point to an inherent defect in the molecular bonds of his biolism, the result of ages of inadequate food, and of extreme climatic conditions. The Native's great passion for the Allyl and Benzene molecules is a demand of Nature, a wisdom derived from ages of experience, a wise empiricism which has so often preceded exact discovery.

I could here illustrate the same general principle from European experience. To apply such principles wisely we must approach disease with "humility of pretension and confidence of hope"; we must have felt the power of what Coleridge called the "Historic Method."

These general remarks will explain how it is that I encourage the use of the onion in the delicate prephilisical young European, whose lung apices, or apex, tend to die too early in the whole-body life of the individual; and no less so of the onion and Aromatic Seeds (Benzene molecule) in the expended vital "energies" of the Native of India, whose organic tract—in the mucous membrane of the big gut, the fundamental primar idee—tends to ulceration or premature death. They will also explain how I at once encouraged B.W., female, a child, to eat those kinds of food for which her system longed—cold meat, potatoes boiled in their jackets and bones—though I fear no can I doubt that this change of diet led to her rapid recovery. One of my most vivid remembrances of practice, both with Natives of India and Europeans, is that of the immense good of even small supplies of that and much craved food.

In Cornwall and the West, from forty to fifty years ago, it was the fashion to debar the child in fever from cold water as a drink; I see sometimes the same practice of withholding cold water to-day. The Poet here, as so often, precedes the Maa of Science—

"... 'Tis a little thing
To give a cup of water; yet its draught
Of cool refreshment, drained by fever'd lips,
May give a shock of pleasure to the frame
More exquisite than when the sun does shine.
Renews the life of joy in happiest hours."

"'Iom," Act 1., Scene 2.

I will now give an analysis of the thirty-four cases of so-called Indigestion in Europeans. I can but make a few remarks of a suggestive character. No amount of trouble combined with the greatest interest, and it may be, justly large views of the problems will make one confident and assertive in such cases. The mental exercise of the diagnosis is an exquisite study; but a wise man would have to confess his difficulties in unravelling the Neuroses of evolving womanhood. In looking back over my lists of "Indigestion" and Gastrodynia cases, which extend over twenty years, and knowing often the subsequent history of the patients, I feel sure that some of the most seemingly pronounced c
cases—barring undoubted haemorrhage—of gastric ulcer, I have been mainly Neuroses. Following the records of my patients' statements, my thirty-four cases seem to group themselves as follows:—Ten cases of gastric ulcer; twenty-two of neuroses, with pain after taking food, at the epigastrium, in the left infra-axillary region, and round to the spine; one where the pain was confined to the sternum; one in the region of the colon. In my ten gastric ulcer group, one only had haemorrhage. It is impossible, therefore, to absolutely discriminate the other nine from some of the twenty-two neuroses group. I was often in complete doubt whether I was in the presence of gastric ulcer or of a neurosis with gastrodinia.

The ten cases entered as gastric ulcer were as follows:

<table>
<thead>

The treatment usually was a combination of Bismuth, Glycer. Peps., with min. v. of Liq. Mophr. mur.; or sometimes Acid. Mur. dil. was given in place of Bismuth. A paramount aim was to secure the action of the bowels once a day, often by means of the Pil. Aloes, et Fer., to thus seek to restore the fundamental, far-reaching, and natural activities of the great organic tract and basis of animal being. The diet was rice, sago, &c., as milk puddings. I encouraged the use of the banana and stewed fruits, and a little lemon juice squeezed over their rice, &c., puddings.

I quite recognise the wisdom of the hospital treatment of gastric ulcer—rest and opium, rest of body and of opinion, &c., but in Dispensary practice we see disease in its inception, in its wide and exquisite earlier correlations; we are quite in a different age or stage of the processes which make for the final embolism and actual ulcer; and thus a wider and more general treatment may be called for.

The gradation between those which I have classed as Gastric Ulcer and those classed as Neuroses was often insensible. One saw continuity rather than definite lines of demarcation. The twenty-two cases which I have grouped as Neuroses are shown in the following table:

<table>
<thead>
<tr>
<th>Duration of illness</th>
<th>1 year</th>
<th>6 months</th>
<th>3 months</th>
<th>2 months</th>
<th>1 month</th>

The treatment of these epigastric, &c., Neuroses was mainly as in the former series. I avoided bromides. Great importance was attached to the restoration of the daily action of the bowels, usually by means of the Pil. Aloes, et Fer., or, if the menses were regular, and no haemorrhage existed, by some other more "simple" (?) aperient, such as Pil. Rhein. Co., or Pil. Coc. c. Hyos. The use of fruits was urged, and especially to drink at bed-time the juice of half or a third of a lemon, in half a tumblerful of warm water. When one recalls remembrances of the great good which accrues to Natives of India, who have often very numerous ulcers of the big gut, from the free use of lime juice and tamarind, combined with the onion and a little garlic, or tamarind itself eaten freely, there will exist, but little room, even of the idea of ulceration of the stomach, of the use of "acid fruits."

Such is the longing for fruits among the poorer Natives of India that it was a common occurrence for the women, even casting aside the terrors of breaking their "easte" or "arack" (lime-juice). Much as Europe has given the East during the past century, the East is no less pouring on Europe its harvest of an old civilisation. The philosophy of the East, in all the realms of thought, feeling, and practice, has never yet been fully or fairly presented to the European mind. None the less, vast streams of light have reached us. In Medicine, our dogmatism of Latinizing and purifying must and will feel the influence of Eastern Ideality. In the expended vitality of Eastern bioplasm, and in its diseases, I was struck with the Natives' passion for certain foods in their nascent modes—the onion, gark, aromatic seeds; nor could I exclude the use of opium from the same category.

Neuroses, or ulcers of the stomach, were among the poorer industrial classes, and I feel sure that "Mental Therapeutics"—a bright, hopeful demeanour with them—is of no less value than are our drugs and prescribed diets.

If we hold the hypothesis of cosmic evolution, i.e., of the orderly evolution, in continuity, of what we hypothetically and tentatively call "matter," also of our mental and spiritual qualities, or as expressed is the teleological language of Bacon, 'For certain it is, that God worketh nothing without causes'; or as expressed by the old Eastern Poet, "And in thy book all my members, were written, which in continuance were fashioned, as when yet there was none of them," we shall esteem mental, and what we call spiritual therapeutics of modern value; and more scientific, than is the use of our drugs. The physical, mental, and spiritual are all of one great continuity, and all equally belong to the broad-minded physician.

Bacon's philosophy is full of great deductive ideas of unity and continuity. He says: "But it is manifest that Plato, in his opinion of Ideas, as one that had a wit of elevation situate as upon a cliff, did descry, 'That Forms (i.e., Ideas, Laws) were the true object of knowledge,' but lost the real fruit of his opinion by considering of Forms as absolutely abstracted from matter, and so turning his opinion upon theology, were with all his natural philosophy is infected." ("Advancement of Learning").

In the old days they were often true and wise physicians who sent their neurotic patients to the Holy Well.

A distinguished General once said that "ignorant savages," fighting in their own native methods, should never be despised. I am writing now on Indigestion, not in view of gastric ulcer as seen in hospitals, in the final stage; nor am I treating of the grand bio-chemical and physiological discoveries which bear on digestion; but am dealing with the phenomena presented to an observer practicing among the masses of the poor and hard-working—mostly women; and it cannot but be that a faithful portrayal of Nature, in her earlier, wide, and varied deviations, may be of value. I am in the position of the "ignorant savage" using the primitive methods of observation and experience.

The difficulty of diagnosis in cases of Neurotic Indigestion, the frequency with which they are treated as gastric ulcer, induces me to cite a few illustrative cases. L. B., female, aged 10, had suffered from pain at the epigastrium, after taking food, for two years. The pain came on hour after eating, lasting one hour, and going off often with flatulence. She was pale and anemic; bowels regular; menses regular. A pre-schooled Potassa bicava, Amonium Aromat., Tinct. Zingib. fort., also reduced iron lozenges. In one week she was much better; at the end of two weeks was quite well. On the same day came J. D., female, aged 23, who had suffered for two years with pain,
From a practical point of view, I may cite that long continued (months or years) and severe epigastric pain, with all the symptoms of gastric ulcer, have in different cases disappeared during pregnancy, during, and for a week or two after, the menstrual period, and during the existence of an attack of eczema.

As I look over my comparatively classified records of cases of Indigestion, I am still in doubt, even with the light of their subsequent course, as to whether many of them were epigastric neuroses or real gastric ulcer. In young women of rich, full nature, in the period of their evolution, a well-nigh passionate love of, or temper, may for a year or two be the source of a neurotic Indigestion simulating gastric ulcer.

The differential diagnosis is aided by giving the patient's tongue "r̓ope" on subjects off her disease. She will thus often betray other neuroses, and her true state.

In treatment one has to look all around, to view the system in general &xi;quently and without haste, to restore the action of the bowels, i.e., of the primα via, the fundamental organic tract, on which, in fact, life and function depend. In European civilization the most elementary decency and habits of life are neglected. It is impossible to imagine a Hindoo woman of any caste, or a Moslem woman, neglecting what is essential in reference to food, the action of the bowels, or other essentials of their being; but in our Society outward show and "appearances" have usurped the place of the old Eastern wisdom.

The Irish peasant is wise in saving the salts of the potato in his stew. The Eastern people crave for "acid fruits," vegetables, aromatic herbs, the onion, &c.; in Europe, both young and old are often debauched the use of fruits, potatoes, onions, pickles, &c.; the young person's "breath has thus often a semi-fecal odor, the whole system is corrupted from this, the most elementary principles and conduct. If young people would encourage the daily habit of the action of the bowels, by the use of fruits, by retiring daily, successful or not, at the same hour, by a daily little self-shamoothing of the abdomen, by following the example of our Eastern brothers and sisters, of simply "squatt-ing" for purposes of defecation, in place of the unnatural position of the seat, there would be less Indigestion, and fewer cases of morbidity.

There can be nothing more revolting to the Hindoo than using a w.c. in common with others. He retires to the field set apart for such uses; the pigs and carrion birds are the scavengers, the scavengers, the boatman on the great rivers, he slings a little wooden perch over the prow of his boat, and does the after washing by dipping up water with his left hand. There is no shame.

* Except among the poor, I prescribe one of the many mineral waters as an occasional aperient, as such have a far more searching general influence on functions than have ordinary aperients. I have often found a restoration of the action of the digestive tract, and a cure of most obstinate cases of constipation, from the habitual use of lemon juice, in hot water, at bed-time. Various types of indigestion will vanish through its use; body, mind, and feelings will all be benefited.

Nomenclature, and the names of disease phenomena, limit our minds from a wide, just, and general view of pathology. I cannot doubt that the final well-marked gastric ulcer, has a very wide and general basis, and correlations in the system, biological and pathological continuity between these prevailing neuroses and the final embodiment and ulcer; the widest and most general biological conditions are involved.

Similarly, in the Native of India, his prevailing and extensive ulceration of the big gut is but a later stage of the widest general conditions—of conditions historic, indeed, in his race—for ages underfed, the subject of "malaria" from early childhood, his life exposed to the extreme dry heats and great rains, and
all this in an Aryan Race, of probable north-western origin, not yet acclimatised to India.

There is a parallelism between the expended vital energies of the Native's bioplasm, and that of the young British peasants' and factory girls' vital condition, which tends to gastric ulcer.

In the treatment of these epigastric neuroses, I have not, right but that recovery is much aided by inspiring the patient with a joyous and happy hope. This is quite as "scientific" as is the use of drugs. Buckle says: "Poetry . . . is a part of philosophy, simply because the emotions are a part of the mind. If the man of science despises their teaching, so much the worse for him. He has only half his weapons; his arsenal is unfilled." The psychical—mental and spiritual—are parts of the organic evolution, as primary and absolute as what we call the physical; all are in unity, correlation, and continuity.

I conclude with the recital of one case. Nellie W., aged 14, was a tall and well-developed girl; her menses began at ten years of age, and appeared every two weeks after, lasting on each occasion one week, and being profuse. She was brought to me for pain at the epigastrum, the left hip and thigh, and the head. The bowels acted but once in five or more days. I found her to be a bright but thoughtful child. She said that she had had pain and a "jumping" at the epigastrum, after taking food, for two years; it lasted half an hour. She had vomited after nearly every meal for eighteen months; her hair suffered a headache for two years; and the pain in the hip and thigh for one year. I found no sign of hip disease. I concluded, from the wide area of the pains, from her general history, from the absence of objective disease, and from her type, that the case was a neuritis, correlating with a peculiar conviction which evolved the menses so early in her life and so profusely. I prescribed Pilocarpine and Caffeine, as needed; also a mixture of dilute muriatic acid, dilute Calomel, and Ginger. Fort: also the free use of lemon juice and fruits. But I sought to send the child off in a joyous spirit. In less than a week all the pain at the epigastrum, "jumping," and vomiting ceased, and she has remained well, but she has a little pain at the hip when the menses are on, obviously neurotic.

I have already in this paper said enough on the general wide principles of biology, pathology, and therapeutics which underlie this case of Nellie W., both as to its nature and treatment. The case, in its history, symptoms, pathology, and recovery, illustrates what Bacon calls an Illuminating Instance.

ACID PHOSPHATE OF SODIUM AND ADRENALEN IN VESICAL DISEASE.

By WILLIAM DE C. WHEELER, M.D.Dub.

Several cases of chronic cystitis having come under my daily note, one case complicated with urinary hemorrhage, a note on the treatment found most efficacious in both conditions may not prove uninteresting to those who have not attained good results by employing the ordinary classical methods and drugs in cases unfruitful for operation.

In the first case, a gentleman, aged 85, with a history of gout, consulted me, with the well-known story of frequency of micturition, especially at night, dysuria, and of urinary hemorrhage, with no enlargement of the prostate could be detected per rectum, and a catheter No. 8 could be passed with little difficulty; about six ounces of residual urine was drawn from the bladder after the patient had satisfied himself it was empty. Some years ago I had removed his stone from the kidney. The urine was acid, contained oxalates and urates, and a quantity of blood, but no epithelial shreds or casts.

An alkaline medicine was prescribed, and the gout treated, with the idea that the hemorrhage might be associated with the passage of "gravel." In this case the use of the cystoscope was not made recourse to on account of the patient's advanced years, and an extremely sensitive and nervous disposition. Sufficient to say, that one day after drawing off the residual urine, a violent haemorrhage occurred, notwithstanding the gentleness practised in passing the catheter. This, as it afterwards turned out, was not due to catheterisation, but at the time it appeared to me that possibly a small portion of a villous tumour or other growth was detached. The hemorrhage on this occasion was therefore not treated locally, but continued for six days, the patient passing water every ten minutes lades with blood. An operation was refused, so the treatment consisted in absolute rest, morphia suppositories, ice to perineum, large doses of calcium chloride, and hypodermic injections of ergot; at first all these drugs were used simultaneously, each having a distinct duty to perform. On the sixth day the hemorrhage had entirely disappeared; on the third it was at its height; on the fourth the blood was passed in clots and not so frequently, but with much pain. The patient made a good recovery, only to get another attack at a time when no catheter had been used. I at once passed a No. 8 French catheter, washed out all blood clots, and injected a weak solution of the adrenalin chloride of commerce. About half a drachm in an ounce of hot water was the strength used, and observed, the patient, though micturating frequently before I arrived, and passing quantities of pure blood, after the injection of adrenalin chloride had no further recurrence. The patient has remained in perfect health on a regular diet, without any medicine, and no blood in the urine, except when it was necessary to inject the adrenalin. An attack similar to his first would have certainly ended fatally. This was only avoided by the treatment adopted. He remains now for three weeks without any blood in the urine, when he gets a severe hemorrhage, to be checked again by three or four injections of adrenalin.

The same patient in the intervals suffered from a chronic cystitis with ammoniacal purulent urine, and as in other similar cases, I have found without exception that the administration of acid sodium phosphate NaH₂PO₄ is the most beneficial, especially when combined with a urinary disinfectant.

R. Acid. sod. phosphat., 2 drachms, Urotropin, 2½ drachms, Influs. urei uris, ad 6 drachms.

Sig. ½ oz. t.i.d.

This is the prescription employed with excellent effect in three recent cases. The patient complains greatly of thirst when taking the medicine, and it should be given if there is any nephritis or albuminuria. In one case uremia was supposed to have arisen in consequence of employing the drug in cystitis when the kidneys also were diseased. In the above note I only refer to patients unfit for operation. A suprapubic cystotomy, or removal of a tumour, in suitable cases is the proper procedure for a surgeon.

In the three cases I have lately met with the acid sodium phosphate had rendered ammoniacal urine acid in twenty-four hours.

Care should be taken that the chemist does not make up the prescription with the official sodium phosphate Na₂HPO₄ instead of the acid sodium phosphate NaH₂PO₄, the normal urinary acidulant. This mistake occurred in one instance, and the chemist having never before seen the acid sodium phosphate prescribed. The symptoms I detail above follow closely those of villous tumour, i.e., intermittent profuse hemorrhage, with no other signs or symptoms of stone or malignant disease. The man being weakly and aged, 85, excluded operation or even cystoscopy, even if he himself should consent to such a treatment. The adrenalin acts admirably when there is hemorrhage; the acid sodium phosphate saved him from many of the terrors of cystitis. He is at present well and out everyday for a walk.
THE ETIOLOGY AND PROPHYLAXIS OF MALARIA. (a)

By DRS. HUERTAS BARRERÓ AND GUSTAVO PITALUGA.

[Specialy reported in the Medical Press and Political Circular.]

The relation between malaria and mosquitoes of class Anopheles was established, micro-biologically and experimentally, by Grassi in 1858; by the elder Macdonald, of Rio Tinto, Huelva, 1900; by Huertas and Mendora, of Caceres, 1901, by Pitaluga, Catalogal, Valencia, Balearic Isles, 1902; and in Portugal, by Bettencourt and Ferreira and others. 1901-1902. The studies of Señores Gil y Morte (El Paludismo, Valencia, 1899), of Rioja and Martín (Discurso Inaugural, Oviedo, 1902), and others largely contributed to establish in Spain the theory of the transmission of the hematozoan of Laveran by the bites of mosquitoes. The theory did not at once receive general acceptance; it was objected to by Dr. Gonzalez Rey (Revista Médica de Sevilla), 1900; by Dr. Pascual de Sande (El Médico Titular), in 1902; by Dr. Sarmento (A Medico Lisbon, 1904). These objections have to-day no more than an historical value. They were completely overthrown by the Italians Grassi, Celli, Marchiafava, Bignami, Dionisi, and others; in Africa, by Hans Ziemann, Koch, Ross, Billiet, Ament; in the East Indies, by Ross, James, Robert, and others. The clinical symptoms of malaria are caused by three species of parasites, and these species are distinct one from another, and are not varieties of one species: (1) Plasmodium malariae, which produces quartan fever; (2) Plasmodium vivax, which produces tertian fever; (3) Laverania malariae (hemamosoeba precoex, hemamoeba immaculata), which produces estivo-autumnal fever in all its perversities. The relation between the mononuclear cell and the hematozoan (that is to say, those of sexual reproduction, endogenous multiplication, and sporulation) and the access of the malaria fever has been clearly worked out, little by little, by the classic labours of C. Golgi. The relation between the relapses, the recurrence of the old malarial fever and the outbreak of the autumn epidemic has acquired a marked importance. They have in all probability a virgin reproduction—that is to say, a reproduction of sexual forms in the blood of the patient, after a period more or less prolonged (sometimes very long), after the acute attack. The macrogametes of the macrogamet, or female spore, preserves the property of reproduction by fission, thus preserving its functions and biological characters in the viscosa; at other times they produce a fixed parasites, which form the mature sporozoites of the blood of the mosquito; they may give birth to new generations of spores, which invade other hematozoans. Canalis, Grassiet Feletti, Mannsberg, Hans Ziemann, and others have seen, showing bodies (speros of Laverania, in severe autumnal fever of the Italian and tropical of Koch) which had a true nuclear division; Schaudinn has watched the whole parthenogenesis in Plasmodium vivax. But this is of the utmost importance in this connection is the possibility of fresh infection by the Anopheles of countless numbers of sexual parasites, in the months of June and July, when the mosquito bites most freely. This new infection furnishes the breeding of chronic patients with the only form (sexual) of parasites that are able to develop in the stomach of the mosquito and produce a new generation of sporozoites. This parthenogenesis is the basis of the sporulation, its limits, its site of election, and so forth, are all unsolved problems for the present generation of scientists. If we once more consider the germination reproduction seen in cases of tertian and quarternium fevers, we, according to Bignami, see the production of the spores of which relapses are produced. In all cases in which we have studied the mechanism of the recurrence of attacks, we found ourselves at one with Grassi and Dionisi (If Politiconio), Celli, Ross, James (Malaria in India), who attach great importance to the diffusion of the epidemic during the months of June and July. These fevers—with, we had better say, the parasites which remain quiescent in the blood of chronic patients—give evidence of vitality on the recrudescence of the fever, and constitute a permanent link between the outbreak of one epidemic and that which follows. The epidemiology of malaria presents many difficulties for solution in many things; but from our existing knowledge we are entitled to consider malaria as truly an infectious disease. The study of the different forms of malarial fever from a scientific standpoint is imposed on the profession; it is our duty to undertake the solution of the problems presented; its results may not, for the present, influence its therapeutics.

Two questions call for attention—the pathology of the disease and its parasitology—both of which we propose to rapid review.

The Parasite of the Quotidian Fever.—From both the clinical and the pathological standpoint this fever has been studied, first by Marchiafava and Bignami. But naturally the great similarity of this plain variety of the parasite to the Laverania form, which produces the severe tertian estivo-autumnal fever, is recognised by the authors. They, however, say that when the adult forms are watched during a paroxysm of fever, or when an access of the fever is in a slight degree of mitigation, a slight difference may be noted—that is to say, the adult forms of the tertian estivo-autumnal fever occupy one-third of a red cell or more, with pigmentary points, movements distinctly marked, and with their forms dendritic; on the other hand, in the parasite of the quotidian form is of smaller size, is less active in its movements, and sometimes is immobile. Koch never found any grounds for this distinction. But the clinical fact that a quotidian form of the fever exists is undeniable. Finally, in endeavouring to prove experimentally the production of quotidian attacks by inoculating the blood of a patient who suffered from a typical attack of this form of fever every time we secured a species or variety of the parasite. On the addition of an endogenous multiplying parasite to the same we produced a severe quotidian attack. The morphological characters were not sufficiently distinctive to enable us to distinguish them. Mannsberg affirms that the spores which produce the quotidian forms are non-pigmented—that is to say, when the parasite has completed the whole cycle of its evolution in the mosquitio it remains uncoloured. This parasite has been observed by Marchiafava and Bignami and others, but its presence is not constant, and it is not shown to be a parasite of the quotidian fever. It corresponds to the fixed parasites (morphological) of the Hamamomia immaculata of Grassi and Feletti (1892). Labbé, who is alone in his views, looks on it as the pathogenic parasite of pernicious malaria, and classifies it as the Plasmodium malariae immaculatums, and it places it in a subspecies under the name of the Hamamomia of Grassi and Feletti. We must allow the question to remain for solution.

There is, however, another question. We have to consider the variety and characters of the parasite of estivo-autumnal fever, which seems to give a chronic form of malaria, with definite relapses and marked secondary lesions, which unmistakably differ from those of the acute type, yet has characters of pernicious suddenness common to tropical and subtropical forms (Laverania malariae, varietas mitis, and L. M., varietas pallida). This classification is adopted by Grassi as suitable for clinical observation and epidemiological study; but it adds nothing to our knowledge of the life-history of the parasite, or of its germination, its development, or of its sexual history in the mosquitoes.

The epidemiology of malaria in Spain is still incomplete. The following are the principal observations made:

1. Simple tertian fever (Plasmodium vivax), occurring sometimes in September and October, and more rarely in November and December. The fierce malignant form, occurring principally in July and August, is

(a) Paper read at the International Medical Congress at Madrid.
attributed to _Laveranid mitis_. In Gerona, at the head of the Bay of Rosas, Ampurdan, and Figueras. In Barcelona, in the plains of Leobregat, Castelldels, in Lerida, in the mountains of Urgel to Balaguer, and Cervera to the north-east. In Zaragoza, from Moncorgo to the mouth of the Ebro, and in the valleys through which it flows, from Cortes and Puebla. In Tarragona, throughout the delta of the Ebro, from Tarragona to Sagunto. In Castellon, the Valley of Miares to the city of Saguntum. In Balears, the island of Mallorca from the north to the south east. In Cucuca, the Valley of Guadaira on the north, of Huelva of Jucar. In Catalonia, the Valley of the Tajo, Tajuña, Henares, and Jarama. In Madrid, the Valley of the Guadarrama, Valencia, the Valley of the Turia, of the Jucar to the Gandia on the south. In these last provinces the fever is not so prevalent as in the eastern provinces, pernicious only in the autumn. But it is the common form in the provinces of Caceres, Badajoz, Huelva, Seville, and Malaga.

2. Mosquitoes of the class _Anopheles_ are found in all the malarial regions, either alone or accompanied by different species of _Culex_. After the observations, above referred to, of MacDonald, in the province of Huelva (1890-1900), we have recognised, caught, and examined mosquitoes in 1901 and 1902 the _A. maculiger_ in Barcelona, Valencia, Lerida, the Island of Mayorque, Madrid, Tarragona, and Caceres. We found the _Anopheles pseudopictus_ in Prat and in all the province of Caceres. _Anopheles bifurcatus_ in Prat and Sampedro. On the basis of these observations we have been able to make some interesting observations. Many of our collected specimens were found to be infected, some in the alimentary canal and some in the salivary glands.

3. The hydrographic conditions of the malarial regions varied notably. The vitality of the larva of the _Anopheles_ is very much greater than biologists generally think. The geological characters exert a marked difference on these conditions. In conclusion of this I may say that during the past two years I found larvae and adult _Anopheles_ at very considerable altitudes. We have found, and with local manifestations, malaria at the foot of the Sierra Guadarrama, 800 metres high, and we have found malarial fever in the provinces of Toledo, Cordova, Jaen, and in Granada at points equally high.

4. The course of the epidemic season, as we have noticed above, confirms in Spain the line of separation between the attack of the past season and their winter relapses, from the outbreak following the fresh mosquito infection during the so-called season (June and July), and the winter relapse following the return of the _Anopheles_ to the breeding place. The most striking and noteworthy epidemiological fact, to wit, the return of a large number of infected troops from the Island of Cuba and the Philippine Islands (1898-1899). As a consequence, these years have been the foci of malaria, distinguished in Spain, as they remained in a transient and generalized, that are the result of the cultivation of rice undoubtedly favourable to the development of the _Anopheles_ larva, and to the persistence of the endemicity. In the case of rice fields we do not adopt the mechanical methods of protection nor the medical. We attach the utmost importance to the betterment of the soil and the bringing of the land into cultivation, and we urge as the true prophylactic on the State, even in the face of all the difficulties, to (i) prevent the introduction of infected _Anopheles_, and (ii) prevent the mosquito from re-infecting chronic patients (those whose blood contains the sporozites or manifestation bugs of previously infected mosquitoes).

3. Mechanical prophylaxis consists in the protection of the whole dwelling-house in the malarial district by fine metallic network, and the protection of the person with gloves, veil, net, and so forth. The mechanical protection has two effects: (i) It prevents the individual from being bitten by infected _Anopheles_, and (ii) it prevents the mosquito from re-infecting chronic patients (those whose blood contains the sporozites or manifestation bugs of previously infected mosquitoes).

275

care was taken that fully 60 per cent. of those in the infected area escaped. We think it the duty of the State to see that houses in the infected areas are protected and that labourers and workers out of doors are provided with suitable protection.

The Italian Government has recently enforced the use of protectives, and the results have not only realised expectation, but have exceeded it. In adopting this method care should be taken that the meshes of the house lattice should not exceed 1 mm. A larger mesh would impede the entrance of A. bifurcatus, v. nigripes.

4. (a) Under the prophylaxis of malaria by medication, we must consider the cure as well as the prophylaxis of acute and chronic cases. (b) The prevention, in a strict sense, of the attack of malaria by daily doses, or, better still, of doses at regular intervals, according to the school of Koch, of preparations of quinine during the whole period of the season. We consider it unnecessary to comment on the theories of the action of quinine on the development of the disease. It appears to suppress in the blood of the malarial patient the parasitic germs and prevent their development, or to remove them on one of their instants. As we have said, malaria is truly a contagious malady transmitted from man to man by the agency of the mosquito.

To stamp out this malaria is the duty of the State, by establishing strict rules for the prevention of the disease. The pre-epidemic seasons, that is to say the winter and spring, should be utilised to prevent and control the eggs of quinine, arsenic, and preparations of iron, the parasite of malaria, during its cycle within the human body. If the quinine dispensed from June to December had been used during the winter and spring seasons as a prophylactic, the effects would have been most satisfactory. It is during this season that the chronic cases call for the alkaloïd. To obtain the full prophylactic properties of quinine a large dose should be given every fourth or fifth days and then an interval allowed of five or eight days. (Koch). We do not, however, think that this method has any special advantage over the usual daily mode of administration. The dose generally prescribed by us is 30 centigrammes of quinine daily with one milligramme of arsenic, and we find this is sufficient to neutralise the effects of the parasite in its early stages of development on its introduction into the blood.

It is necessary to eliminate the disease in chronic patients by doses capable of killing all the different varieties of the parasite. To be able to bring about this desirable result, and to produce it safely, we must solve many pharmacological problems.

BRITISH SANATORIA FOR CONSUMPTION.—XI.

[BY OUR OWN SPECIAL MEDICAL COMMISSIONER.]

THE VALE OF CLWDY SANATORIUM.

The conspicuous success which has resulted from the rational application of the so-called "open-air" method of treatment has led to a rapid upspringing of well-equipped sanatoria in various parts of the country, and even the little Principality of Wales can now boast of at least two excellent private institutions for the management of phthisical cases.

Certain districts in North Wales are peculiarly suited for the carrying out of the hygienic conditions of convalescence, and afford climate and other advantages which have for long made them appreciated as holiday resorts and health stations. The Vale of Clwyd Sanatorium, at Llanbedr Hall, near Ruthin, in Denbighshire, although only open a few years, has already distinguished and accomplished much excellent work. It is situated in a particularly charming country, rich in natural beauty, and full of archaeological and historical interest. The sanatorium has been wisely arranged to meet the needs of modern methods by a judicious and skilful adaptation of a country mansion, Llanbedr Hall. It is surrounded by extensive park land, and by its seclusion and distance from high roads and habitations ensures quiet and freedom from dust so essential to the patient of phthisis.

The sanatorium is well situated on the slopes of the Clwydian range, at an elevation of 450 feet, and has a western aspect, with charming views which should exercise a valuable psychological influence in the restoration of the tuberculosis patient. This provision provides for excellent shelter from the east and north-east winds, while allowing for a plentiful exposure to sunlight.

Behind the sanatorium the Clwydian hills rise to a height of 1,800 feet, and not only afford much protection but provide excellent opportunities for graduated up-hill exercise. Immediately around the Hall lie woods of larch and pine and other trees which, while adding much to the picturesque appearance of the outlook, are well suited for the needs of the consumptive. Charming lawns and old-world gardens and innumerable walks supply the patients with the pleasurable facilities for conducting the "outdoor life" under the best conditions.

The view from the sanatorium is particularly attractive, comprising the whole length of the beautiful Vale of Clwyd, and presenting glimpses of the distant sea at Rhyl, and Snowdon and the Welsh mountains to the west.

The climate is generally well adapted to the needs of the consumptive. In summer it is fairly cool and breezy, and in winter distinctly mild. It is pure and invigorating, and, of course, free from contamination from smoke and organic impurities; fog and mountain mist are exceptional. The rainfall is said to be small, and the soil being porous renders the air relatively dry.

Llanbedr Hall is well adapted to meet the needs of a modern sanatorium. The various rooms have been modified to allow of the full application of the principles of hygienic treatment. All the rooms are provided with hot water pipes and radiators. The water supply and drainage appear to be good.

Immediately adjacent to the main building is an annexe, the rooms of which have been arranged to allow of a practically open-air existence while permitting the comforts of a well-ordered habitation.

The sanatorium is conducted strictly on Nordrach lines. The resident physicians have themselves been patients of Dr. Walther, and are thus peculiarly well fitted to direct the reiteration of the cases under their care.

Great care is taken to avoid any danger of infection. Patients are expected to keep strictly to the walks prescribed, and not to exceed the regulation pace of two miles an hour, unless otherwise directed. Patients are also expected to eat everything that is given them at meals; should they refuse to do so and give no adequate reason, they are subject to dismissal. Eating between meals is strictly forbidden, and the luxury of afternoon tea is generally withheld. The daily routine is carefully marked out and subject of individual study. Rectal temperatures are taken, four times a day, twice being immediately after exercise.

We had the privilege and pleasure of taking a place with the patients at their mid-day meal and were much struck by the admirable combination of strict discipline with the freedom and comfort of English home life. The doctors and their wives take meals with, and freely associate with, the patients and the objectionable features of institutional life are conspicuous by their absence. The dietary was abundant, varied, well selected, and the cooking everything that could be desired.

Treatment, as we have already indicated, is conducted on strictly rational and scientific lines. The physicians and their wives reside with the patients in the Hall, and thus secure a constant and systematic regulation of every patient's life in the best possible
hygienic conditions. Great care is taken in the application of dressings, and it is very hard to give the conduct of graduated up-hill walking.

Ample provision is made for the adequate nursing of cases; the matron is a fully-qualified nurse. There are five guineas weekly, which include everything except washing and alcoholic drinks, the latter being taken only with the permission of the physicians.

The resident physicians and proprietors are Dr. George A. Crace-Calvert and Dr. Cecil E. Fish.

As soon as the peculiar advantages of the Vale of Clwyd Sanatorium become better known we imagine there will be need for considerable extension of the institution, for which, indeed, there is ample space. The grounds are well suited for the erection of hygienic bungalows, and additional open-air shelters will, no doubt, be added, as required.

The Vale of Clwyd Sanatorium may be conveniently reached from any part of the country. The nearest railway station is Ruthin, on the London and North-Western Railway, where a carriage meets patients on arrival. The postal address is Vale of Clwyd Sanatorium, Llanbedr Hall, Ruthin, North Wales; while the telegraphic address is simply—Sanatorium, Ruthin.

THE WESTMORLAND SANATORIUM.

DR. PARKER, Hon. Sec. of this Institution, writes us that owing to a slight misconception on the part of our Commissioner, a relative of the charge patient, a correction is necessary. He says:—"The occupants of the beds acquired by public bodies and groups of subscribers are admitted free (not, as stated by our Commissioner, 25s. per week). This institution was founded for the poorer classes in Westmorland only, the design being to get every bed endowed; out of the 24 beds, 21 are so endowed, the remaining 3 being used for paying patients at 25s. per week, and 4s. per week by non-county patients."

MANAGEMENT OF THE WOUNDED IN NAVAL WARFARE.—II.

Materials for dressing may be preserved with care, but as many days must necessarily elapse before they are actually used, and as their absolute purity cannot be assured, there is a need of having on each ship some handy apparatus for disinfecting them immediately before use.

The greatest difficulty that was experienced in the way of treatment by the Japanese was the management of patients suffering from extensive burns over the body. Not to mention that much time was required in changing the dressings, the sufferers of patients while being washed with antiseptic solution were extreme. On one ship, it happened that owing to the loss of surgical dressing, &c., and the consequently insufficient application of antiseptics, the burns soon suppurated. The chief antiseptic that was used in the hospitals was a solution of carbolic acid, sometimes of corrosive sublimate, and of boracic acid, also iodiform in a very few instances. The dressings were made to be always sterilised before use, and at the same time great care was taken with antiseptic precautions; yet it was not an easy matter to eradicate the suppuration of the wound, and consequently the course of the wounds was generally slow, and a comparatively large number of days were required for treatment.

The nature of a shell-wound is different from that of other kinds, and is very hard to cure. There was a striking difference between a shell-wound and a bullet-wound, even when the wounds were quite alike in their outward appearances.

For the lotion of burns, solutions of carbolic acid and boracic acid were employed, sometimes powders or ointments of boracic acid, iodiform and salicylic acid; but it was found extremely difficult to keep the wounded parts clean. Great pain was complained of at the time of changing the dressings which were accordingly renewed as rarely as possible. But as it happened to be the hottest season of the year, maggots were frequently produced under the dressings, which had then necessarily to be renewed pretty often in spite of the pain. With the purpose of preventing the sticking of dressings to the burned surface, the part was first washed, then fenestrated oiled paper was placed on it, with gauze or cotton wool put over it. But this proved to be unsatisfactory, for the discharge would accumulate under the oiled paper.

Diseases and Injuries.

The total number of infectious diseases during the China-Japanese War was 840, of which 319 were on the field of war, and the remaining 101 on home stations. In the field there occurred 50 cases of enteric, cholera 49, dysentery 55, malaria 128, measles 4, and influenza 37. At home, cholera 40, enteric fever 21, dysentery 16, malaria 22, measles 1, and varioloid 1.

It is a fact experienced by every nation that forces sent on an expedition suffer much from the prevalence of enteric; but in the Japanese navy, during the war, there were no more cases than usual. This must be attributed to the particular attention paid by the medical officers to the cleanliness of the place, and the men faithfully observed the instructions given them with regard to sanitation. However, when a case broke out, no matter whether it was on board or on land, the place did not fail to undergo a thorough disinfection.

Dysentery is very prevalent in Japan from year to year. In 1891, the total cases of the epidemic that occurred through the land reached 155,140, of which 38,094 resulted in death. In 1895, the number was 52,711, of which 12,959 terminated in death. During the war, the army produced 13,009 cases, of which 4,591 recovered and 1,662 died, and 6,739 were either sent to other jurisdictions or could not be traced for some reason or other. In the navy, the sufferers from dysentery were 71 men and 15 women.

During the period of the war, there occurred in 1894 30 cases of malarial fever, and 116 cases in the following year.

In China and Korea, owing to the backward state of their sanitation, no year passes without seeing more or less a prevalence of small-pox. Not a single case of this disease, however, occurred during the war among the Japanese, who had to go ashore on landing parties or other errands, nor among those who had frequently to mingle with the natives while staying in the harbours. This must be considered as a result of the strict enforcement of re-vaccination in the navy; for there are regulations that every man newly enlisted shall be re-vaccinated, no matter whether he has already been vaccinated or not, and that in December each year re-vaccination should be performed on all who have passed five years since their last re-vaccination.

Kak'ke.

Kak'ke has existed in the countries of the East from very ancient times. In Chinese medical books, the first mention of it occurs some two hundred years before the Christian era, and in certain medical works of Japan published a thousand years ago, the disease is mentioned. It seems that formerly kak'ke much prevailed in China, while it has greatly decreased there of late. The case is just the reverse in Japan. Though in Japan the existence of the disease can be traced to a very remote period, it was almost confined up to a few decades ago to a few populous towns and sea-ports,
where travellers crowded from every part of the country, and had never prevailed over the whole land of the Empire as is the case at present. As to the cause of this disease, nothing certain is known as yet. There is a strong belief that the origin of kak'ke is intimately connected with a certain kind of food. Up to the year 1883, the Japanese navy had been greatly harassed by the prevalence of the disease, a large number of the seamen on both land and sea suffering from it every year. The Director of the Medical Department of the Navy instituted investigations as regards kak'ke, as a result of which he made a plan for improving the scale of diet. The allowance for a day's ration per man was eighteen cents, which were paid in cash to ships or barrack, and the food was prepared as they respectively considered suitable, so the quality of food was not the same in all ships and barracks. But it was evident that the diet used in every ship and barrack fell in its nutritious value below the physiological standard. It fell far short of the minimum quantity of nutritious ingredients—that is, 500 grammes of carbohydrates, 50 grammes of fat, and 158 grammes of albuminous substance, which, according to the estimation of Dr. Voit, is indispensable to a man of ordinary health and middle age, who takes adequate daily exercise. And if compared with the minimum quantity of nutritious ingredients of the food needed by a man who takes active exercise—that is, 500 grammes of carbohydrates, 100 grammes of fat, and 45 grammes of albuminous substance—it shows a still greater deficit. Not a navy in the world has a diet of which the nutritious value falls below the physiological standard. Accordingly, in February, 1884, a resolution for the improvement of the scale of diet was passed, and so the former method of paying in cash is now substituted by that of supply of substance.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, Sept. 2oth, 1893.

TREATMENT OF CHRONIC GASTRITIS.

Prof. Robin, who is regarded as an authority on gastric diseases, recommends for the treatment of chronic gastritis the milk diet. The milk should be taken warm, but not boiled; complete immobility should be observed for half an hour after each glass of milk. In the case of obstinate vomiting:

Picrotoxin, 0'05.

Proof spirit, q.s. (to dissolve).

Hydroch. of morphia, 0'05.

Sulph. of atropin, 0'01.

Ergotin, 1.

Cherry laurel water, 12.

Five drops, five minutes before taking the milk, but not more than twenty drops should be given in the twenty-four hours.

Where pain occurs after the milk, one of the following powders should be given:

Calcined magnesia, 4 grammes.

Bicarb. of soda, 4 grammes.

Prepared chalk, 6 grammes.

Divide into twelve powders; or

Pepsin, 0'50.

If there be produced, during the digestion, flatulence, a tablespoonful of the following mixture may be given:

1 ounce of a solution of ammonium, o'20.

Water, 300.

THE METHYLENE BLUE TREATMENT.

M. Meillère, of the Académie de Médecine, has published a lengthy article on the action of methylene blue on the economy as an antiseptic, of which a brief résumé is given here.

The author divides his article into two parts, the first treating the blue of methylene as an agent of clinical exploration, and the second as a therapeutic agent. The diagnosis of renal permeability by methylene blue, vulgarised by Achard and his disciples, has become of current practice. In a healthy subject, the methylene blue appears in the urine half an hour after an injection of one grain dissolved in a gramme of serum. The colour attains its maximum of intensity towards the third or fourth hour, and disappears completely after forty hours. In persons suffering from Bright's disease (interstitial nephritis) the colour is slow to show itself. The prolongation of the elimination after the fiftieth hour is a sure sign of atrophic nephritis when the organ is very imperfectly permeable. Intermittence in the elimination is observed generally in hepatic disease and parenchymatous nephritis. It results that the time taken in the elimination of methylene blue constitutes an important element of diagnosis and prognosis in the functional insufficiency of the renal and hepatic organs.

In detecting an erosion of the mucous membranes, a solution of methylene blue is very efficient, as the colouring matter fixes itself on the excoriation in preference to any other part of the inflamed membrane. As a therapeutic agent, the blue of methylene has been advocated in a variety of affections, both externally and internally. In pruritus, especially that of diabetic women, in ozaena, irritations of the nasal cavity three or four times a day with a 2—1,000 solution; in dysentery, enemas of o'20—1,000. Under their influence the bile returns rapidly in the faces. In menorrhagia, capsules or pills containing one grain; in women, injections of a weak solution; while Pozzi employs it in the same cases to sterilize the vagina of parturient women as a preventive of purulent conjunctivitis in the infants; in chronic suppuration of the middle ear, Gaudry recommends instillations of 15 to 20 drops of a warm 2—1,000 solution. As a local agent, the blue of methylene has given very satisfactory results in epithelium of the eyelids and face, applied in concentrated solution (methylene blue, 1 gramme; alcohol, 5; glycerin, 5).

It is strongly recommended internally by Lippman, Klemperer, Lemoine, &c., for the treatment of neuritis, sciatica, migraine, and zona, or herpes zoster. Delno and Einhorn have confirmed the results obtained by Netchef in the treatment of haemorrhagic nephritis and albuminuria.

Posology.—Externally, the blue of methylene can be prescribed in solution of 1 to 2—1,000 for large irrigations. The concentrated solution, 1 per cent. to 10 per cent., is applied to epithelium.

Internally, the dose of 5 grains daily, in pills of one grain, should rarely be exceeded. The usual dose is three pills daily.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, Sept. 4th, 1893.

In the Korrespondenzblatt f. Schu. Arzte for 1893, Dr. O. Naegeli has a paper on PERNICIOUS ANAEMIA AND ITS DIAGNOSIS.

The disease known as pernicious anaemia was first described in 1868 by Biermer. The autopsies showed a uniform but not a characteristic appearance. Extreme porosity of blood, fatty degeneration of the muscles of the head, "siderosis" of the abdominal organs; later on, the frequent change of the fatty marrow of bone
into red blood-forming marrow was discovered. In 1860, Ehrlich emphasised the importance of the abnormal large blood corpuscles, particularly of the megaloblasts. Later still Laax showed the importance of the heightened colour index of the red blood corpuscles in contrast to the secondary anemias. More recent examination of the blood laid stress on the relative increase of the lymphocytes and the diminution of the leucocytes. The writer's own examination of bone marrow showed the great diminution of the myelocytes, which were replaced by small granular free medullary cells (myeloblasts).

Of the causes, only one was distinctly decided—the bothriocephalus latus. In any case pernicious anemia would not be looked upon as an etiological unit. It was not a morbid unit, but an assemblage of symptoms caused by various etiological factors, dependent on a uniform organic affection, on a characteristic change of the marrow of bones in structure and function.

On the basis of twenty-eight cases observed by himself, the writer describes the diagnosis. The most important feature is the presence of the megaloblast, although these cells are occasionally found in carcinoma ante-mortem. In the twenty-eight cases, these megaloblasts were permanently absent in one case only. The tumour in importance was the diminution of the leucocytes, especially of the granular. This depends on the change of the bone marrow into a marrow with few myelocytes and the resulting insufficiency in the formation of granular leucocytes. The percentage of lymphocytes was much increased. In all the twenty-eight cases the condition of the white blood corpuscle was typical. Diagnostically important was the diminution of the red blood corpuscles and its colour index. In carcinoma the number was scarcely ever below 1,000,000, whilst in pernicious anemia it was often below. ['The lowest number was found by Quincke—143,000.'] Blood plates and fibrin were diminished, whence the absence of inflammatory and thrombotic processes. Retinal haemorrhages were in favour of pernicious anemia, but it was also frequently present in carcinoma. Examination of the stomach showed increased motility; there was almost always absence of free NCl, or a diminution of it. Ferments were often absent or diminished. He believed that pernicious anemia could almost always be made out or excluded at the first examination.

Dr. Muller observed that as regarded the bothriocephalus latus, it was remarkable that in the neighbourhoods of the Geneva and Neuenburg lakes, where bothriocephalus was very prevalent, no bothriocephalus anemia was recognised. It was very difficult to distinguish between cancer of the stomach and pernicious anemia so long as no tumour could be felt.

In treatment, Eichhorst had seen the best results from arsenic.

The Deutsch. M. z. Zeit., No. 68, 19/3/03, contains an extract relating to a

Simple Treatment of Fissured Anus,
by Dr. Luntz. Generally speaking, surgical measures have been resorted to, especially cauterisations, incisions through the sphincter, or, more recently, complete stretching so as to procure temporary paralysis of the sphincter ani. A method proposed by Boas was based on the idea that with regular action of the bowels, the fissure never had an opportunity or chance to form. A mixture of two parts of a solution of soap and one part of a solution of sal ammoniac by daily evacuation of the bowels. Given absolute rest, the ulcer would heal just like any other ulcer would. Boas therefore proposed that the patient should take no solid food, nothing but soups and tea, and should take to drops of tincture of opium three times a day.

This treatment should be carried on for a week, so that the bowels should be kept completely blocked for that length of time. During this period the fissure should be kept dusted with iodiform, orthoform, xeriform, or other powder. If the cure was not completed by the process, Boas proposed that it should be repeated for a second or third time if necessary. He claimed to have treated eighteen cases of ulcer in this way, and that sixteen out of the eighteen had been completely cured.

Fr. Luntz had treated one case in this way and had satisfied himself that the method was effective. The patient was a man, aged 54, who complained of violent pain on defaecation. On examination, a small haemorrhoidal nodule was found, and a bleeding, very painful fissure of 0.5 cm. in length. The case was treated after Boas' method. The patient was kept in bed, and the fissure dusted daily with orthoform. The patient bore it three days; he then began to complain of distension. On the fifth day he wished to have the course of treatment interrupted, declaring that he could stand it no longer. On the sixth day the doctor gave way and ordered castor oil. A copious evacuation followed, but without pain. The fissure was healed. In two other cases, considering the difficulties of the treatment, he abstained from it. In the first case, the fissure formed five days before treatment was begun. In the second case, a man, aged 42, who had suffered from haemorrhoids for about ten years, the fissure appeared about fourteen days before treatment was begun. These patients were treated by oil enema after the method of Fleiner. Both were healed in about a week. Silver nitrate was used once in the first case. The favourable action of the oil enema was due, the author believes, to the drying effect of the oil on the whole tumour of faces, and not the part on the top only as was the case when purgatives were given. This oil also covered the fissure and prevented the immediate contact with the faces.

The oil used was the Provence oil of commerce. He believes that all cases in which there are no old callous induration may readily be cured in this way. The oil enema are also serviceable in cases of haemorrhage from piles.

VIENNA, September 5th, 1903.

Blood Plates—Colouring.

Purchberger read a paper at the Naturforscher on the results of his investigations with "Brillant Kresyblau" on the haemato plates found in blood, with the object of detecting morbid changes which, it was believed, would be an invaluable diagnostic point in the differentiation of disease.

This is a method, Purchberger explained, practised by Levadi, assuring us of greater security in observation, as the blood plates are usually, when the experiment is conducted in health, about half the diameter of a normal red corpuscle. These so-called plates are sometimes round and sometimes angular, but homogeneous with an active ameboid movement. Some of these bodies contain dark granules in the centre, or may be irregularly divided, as if a cleavage were taking place. A few minutes after the colouring has been completed these crystals or plates draw together, forming a dark blue mass on the microscopic field, assuming the figure of a half moon, quite separate from the other hyaline bodies. His observations lead to the conclusion that these figures are more pronounced in, if not peculiar to, myelogen leucocytes.
OSSEOUS CARCINOMA AND HEMATIC CHANGE.

Kast next recorded a case of amputatio penis on account of carcinoma followed by multiple metastases in the internal organs. The blood was found to have undergone the myelogenous leucocytæmia change. The sections of bone from different parts testified that the phenomenon was universal, and evidently distributed from the centre by means of the hematic current. Following the blood examination proved leucocytoæmia, but the real cause of the leucocytæmia was not demonstrated till the post-mortem was made.

DIVERTICULUM OESOPHAGI.

Mintz described the case of a man, æt. 51, who had been under his care for a long time with a diverticulum far down the oesophagus, and immediately above the diaphragm. The patient had suffered, according to the history, for at least two years, and finally died of inanition. There was no post-mortem, but the Röntgen rays had provided him with copies of the dark shadow lying to the left of the spine on the diaphragm. The sound could not be passed into the stomach, being prevented by a stenosis which had been the cause of the obstipation. The consequent depuration in the feces and food that had accumulated, but being void of the gastric juice necessary for the digestive changes of nutrition the food came back unchanged or without any benefit to the patient.

GASTRIC SUPRACIDITY.

Walko repeated the treatment that has often been recorded, that olive oil will cure hyperacidity. He appreciated the importance of the profession that this is an admirable substitute for the usual prescription of atropin and the bicarbonate of soda. He gives 150 to 300 grammes daily, either by tube or mouth. After a few weeks improvement will be observed, and, later, cure will be accomplished by the acid secretion being inhibited.

PATHOLOGY AND THERAPY OF ENTEROPTOSIS.

Kumpf next entered on a long exegetical discourse on the history, pathology, and treatment of the different organs affected in enteroptosis, descending, ptosis, prolapsus visceri, or, in other words, displacement of any internal organ. He credited Glenard, 1885, with the first literary production on the subject, who then termed it "entité morbide," although he admits Richais in 1839, Hufeland, and Virchow for 2 years later (1843), who gave local descriptions of the displacement of individual organs, which he affirms were collected and classified in an academical manner by Glenard, 1880.

The etiology is obscure, while the pathology is so varied that every organ of the body is liable to change its position in some way. Among the displacements he admitted the kidney to be the most common, as out of 300 examinations he found 30 per cent. were nephrophtosis. These would increase according to the age of the patient, as he finds this to rise to 42 per cent. These data were obtained from post-mortems and not from diagnosis alone.

The next in frequency was the transverse colon, which was closely associated with nephritic changes. He laid down one general diagnostic sign for the guidance of the clinician, viz., by pressing the finger firmly down along a line, passing from painful part behind, under the arch of the ribs to the umbilicus. The colon and transverse colon could be isolated by blowing up the large intestine from rectum. He added for the information of members that the hepatic flexure was not so commonly displaced as the middle portion of the transverse colon.

Auffrecht concurred with Kumpf in the opinion that Glenard's "entité morbide" was not sufficiently recognised, as very many of those indefinite cases of neurones and so-called hysteria were nothing else than one form of enteroptosis. He had endeavoured to make an estimate of these cases in his own practice, and found 80 to 85 per cent. suffering from enteroptosis.

The treatment must depend largely on the nature of the deposits, whether slight or extreme, and the organ displaced. In the case of the uterus rest and a bandage may be sufficient; if slight in nephrophtosis the same treatment may be enough; when the bowel is affected pain, flatus, &c., may require medicaments such as

B. Resorcin sublimati, 0'3 gramma.
Extr. strychnia, 0'01 gramma.
Divide into twenty powders.

Sig.—Give one every third day.
Extr. strychnia, 0'03 gramma.
Divide into twenty powders.

Sig.—Take one powder after each meal.
Benzo-naphthol and salicylic acid are also good.

ANCHYLOSTOMIASIS.

Goldmann, from Brenner, reported the reduction of anchylostomiasis from 80 per cent. to 12 per cent. by the simple enforcement of sanitary regulations in the respective mines. This disease has of late years been giving the proprietors of large mines considerable concern, and in order to reduce and obviate the danger they have conferred with the medical officer, so that every means might be applied to stamp out the disease. Goldmann showed a number of photographs giving the history of the parasite from the ovum to the fully-formed worm.

He has no intermediary to show. The infection, he contends, is carried about by the mines by means of the air, whence it gains admission to the alimentary tract where it commences germination. Method of treatment was simply hygienic, by having wooden cabins in the mine for meals, the insides of which were painted with the chloride of lime. Every miner was forbidden to eat in the mine, but must wash and change before entering the cabin, the air of which was filtered. On leaving off work the régime was enforced with the addition of a bath.

The faces were all disinfected, and 15 grammes of the extract of Filix mas in thyrol to be taken occasionally. Calomel followed by turpentine is sometimes administered where the worm is present. This has reduced the attacks from 80 to 12 per cent.

The Operating Theatres.

KING'S COLLEGE HOSPITAL.

OPERATION FOR FOREIGN BODY IN THE TRACHEA OF A YOUNG CHILD.—Mr. Peyton Beale operated upon a child, æt. about 13 months, who had been admitted with the following history:—Three days previously the mother stated that the child, whilst playing with a nail, had put it in its mouth and "swallowed" it. The child had no symptoms, but the mother had called in a doctor, who, it was stated, had advised bread and milk diet, evidently with a view of getting the nail to pass down the digestive tract. As the child seemed to be unwell in the course of the next two days, she brought it to the hospital, where it was found to have a temperature of 101°, and a slight cough. The child's neck was radiographed, and the nail was very plainly seen to be lying obliquely, head downwards, the point being just level with the top of the sternum. The nail was two inches long and about three-sixteenths of an inch in diameter—evidently a large wire or French nail. The
X-ray apparatus was not working perfectly, and it could not in any way be ascertained whether the nail was in the trachea or esophagus. As there was no dyspnea, and as the child had vomited once or twice during the day, Mr. Beale assumed that it had lodged in the esophagus. The child was therefore anesthetised and the esophagus opened from the left side of the neck just above the level of the sternum. On introducing probes and forceps the nail could not be felt anywhere, so it was decided to open the trachea. This was done through the existing wound on the left side as low down as possible, care being taken of the large vessels in the neighbourhood. When the trachea was opened the child began to cough, and on introducing a probe into the trachea the nail was felt. Mr. Beale then tried to seize it with forceps, but found that the point was embedded in the mucous membrane, and he could neither pull it up nor push it down. The child now had some violent paroxysms of coughing, and during one of these the point of the nail was spontaneously freed, appearing in the tracheal wound, was seized with forceps, and easily withdrawn. The esophageal wound was then stitched up, and an attempt was made to place a tracheotomy tube in the tracheal opening, but it could not be kept in situ owing to the opening being so much to one side. The edges of the trachea were therefore allowed to come together, and a gauze plug placed in the skin wound and a gauze dressing applied. Mr. Beale remarked that although the X-rays demonstrated the presence of the nail, and its size, yet, strange as it might seem, it was not possible to tell whether the nail was in the trachea or esophagus. In a child of this age the two tubes were small and very close together at the level of the sternum, and the rings of cartilage were not to be made out under the X-rays. Perhaps this was partly due to the fact that the apparatus was not working properly. Although it might seem an easy operation to open the esophagus and trachea in a young child at the level of the top of the sternum, it was really not so simple, for the esophagus was not easy to recognise even when exposed, and it must be remembered that only about half an inch of its length was exposed, and, secondly, the left innominate vein crossed in front of the trachea, and the operator was really working in the angle formed by the junction of the int. jugular with the innominate, both these veins being kept out of the way by means of blunt hooks. He did not do a tracheotomy in the middle line, because the risk to the innominate vein in opening the trachea of a child at the level of the top of the sternum was very great, whereas the vessel was in view, and could be kept out of harm's way, in the wound already made for reaching the esophagus. It was an extraordinary circumstance that the child had no difficulty in breathing during the three days that this two inch nail was within its trachea, the slight cough which was present being much more like a reflex laryngeal cough due to some gastric disturbance than one caused by a foreign body in the trachea.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

COMPLETION OF OPERATION FOR ECTOPIA VESICE. (The first part of the operation appeared in " Operating Theatres," July 8th, 1903.)—Mr. Kellock performed the second operation on the case of ectopia vesice. The first operation, reported on July 8th, 1903, consisted in bringing the penis through an opening made by dividing the scrotum and fixing the penis in situ. This had been successful, and Mr. Kellock now proceeded to attempt to obliterate the extraverted bladder. In order to do this, an incision was made round the bladder at the junction of the skin and the mucous membrane, which was deepened until the peritoneum was reached. The whole of the extraverted portion of the bladder was then dissected down until it was quite free posteriorly, without the peritoneal cavity having been opened. When this was quite free, long double horse-hair sutures were passed through the edges of the bladder at short intervals. The free ends of these were then passed along the floor of the urethra and brought out with the penis under the bridge of skin stretching across the position of the symphysis pubis; this completely inverted the visible portion of the bladder, leaving a raw surface in the abdominal wall where it had previously been. The posterior aspect of the bridge of skin was then freshened and the inverted wall of the bladder fixed to it by several points of suture. The ends of the sutures in the bladder wall, which emerged along the dorsal surface of the penis, were left long and fixed by a single silk suture to the inguinal region on either side, thus helping to hold open the passage into the bladder along the dorsum of the penis. The raw surface on the abdominal wall from which the bladder had been dissected down, and the junction of the bladder with the bridge of skin, were then completely covered up with collodion and gauze, and a binder applied. Mr. Kellock said that the operation thus performed in two parts seemed to him to give better promise of a favourable result than where attempts were made to cover in the bladder with flaps of skin taken from the abdominal wall; the bladder so made was almost always a source of subsequent inconvenience to the patient: it would hold little or no urine, and was constantly getting incrusted with phosphatic deposits. If the operation which had just been performed proved successful, the child would have a small bladder completely surrounded by mucous membrane, and the urine would escape into the peritoneum along the dorsum of the penis, and it would be possible for the child to collect it in some receptacle. He proposed to deal with the raw surface in the abdominal wall by a skin graft, or by subsequently transplanting a small flap of skin from the immediate neighbourhood. He thought, too, that on some subsequent occasion it might be possible to close over the open urethra on the dorsum of that part of the penis which now protruded in the perineum.

WEDNESDAY, SEPTEMBER 9, 1903.

RECENT SURGERY AND THE BONE-SETTER.

The progress achieved by scientific surgery within the limits of the past generation has been
so great as to merit the title of "epoch making," or even "revolutionary." The possibilities opened up to surgeons by the brilliant discoveries of Lister have done for their art what has been brought about in the outside world by such inventions as the printing machine, the steam engine, or the electric telegraph. Not a few important advances, however, have been made independently of aseptic surgery. The modern treatment of sprains, fractures and dislocations offers a good illustration in point. By the application of the Röntgen rays it is possible to make an exact diagnosis in those injuries, as well as to trace the subsequent course of events, ending in repair or otherwise. The second great new principle in the treatment of the class of injuries in question is that of early movement, both passive and voluntary, and of massage and elastic pressure with a view of limiting and absorbing effusion. The teaching of the schools until quite a recent date was that fixity and immobility were essentials in the treatment of the conditions mentioned. All that is now changed, and there can be no reason to doubt that the alteration in practice is conducive both of benefit to the patient and of credit to the surgeon. The result of the old-fashioned orthodox method ended only too often in stiff and painful joints, sometimes with the addition of tubercle, and of other active pathogenic inflammations. According to recent views, the stagnation of the venous and lymphatic circulation in injured parts treated by fixed apparatus constituted a serious obstacle to rapid and effectual repair. Hence the attempt to restore physiological activity by rubbing and by early active and passive movements. So great has been the rebound from the method of treatment by prolonged rest that early voluntary movements are now commonly advocated in sprains, fractures and dislocations. One important aspect of this change is the prevention of adhesions, and of those secondary bacillary invasions of effused material that were formerly encouraged by the stagnation of the blood and lymph streams. In this way the bone-setters will be robbed of a large class of cases, which, as a matter of fact, must be regarded as the failures of the surgeon under a former and less scientific practice of his art. The happy hunting ground of the charlatan was that margin of cases where for various reasons surgery had failed to establish a firm grip of the morbid condition. The margin of obscure and unfavourable injuries was greatly reduced by the advent of Röntgen-ray methods, whereby the wiles of the bone-setter were to a considerable extent checkmated. It is no longer possible to tell everyone suffering from a stiff or painful articulation that "the joint is out," because there is always a danger that the average intelligent man in the street will seek confirmation or disproof of that assertion by means of a radiogram. The bone-setter will be further deprived of a large part of his unqualified practice by the prevention of post-traumatic adhesions in and around hard and soft tissues by the early application of massage and movement. To shoulder out irregular practice of that kind by the introduction of more scientific and exact surgery is an ideal method of cutting the Gordian knot of the suppression of quack practice. There is little use in shutting our eyes to the fact that the bone-setter battens on the failures of surgery. He is the outcome of an imperfectly developed art. Before the future progress of the healing art it may confidently be anticipated that not only will the bone-setter disappear from the community upon which he battens, but that he will be accompanied in his flight sooner or later by the host of quacks who flourish upon the bodily misfortunes of mankind.

NERVOUSNESS.

NERVOUSNESS, says the author of an elaborate contribution to our knowledge of the subject, (a) seems to be the step-child of medical practice, somewhat disliked, half understood, certainly neglected. The author speaks in a tone of dignified reproach that so little has been done to stamp out a state, or physical condition, which may unquestionably be classed among the "undesirables." One turns with eager curiosity to find out what prophylactic and curative measures the author recommends, for though the subjects are many the remedies are few. The first and most effective preventive of nervousness, says our author, is a reasonably long line of first-rate forbears—i.e., ancestors. This is an unfortunate commencement, because the choice of parents, immediate and remote, is not one of the attributes of childhood. All the child can do, when he arrives at years of discretion, is to bemoan that his neurotic ancestry should have begotten offspring who fatally inherit the tendency. Proceeding, we are told, and the statement is one which defies contradiction, that next to the omnipresent, inevitable laws of inheritance, comes the never-ceasing, forming power of environment. Here, again, few of us, at any rate during the formative period, are at liberty to select our environment, as many of us know to our cost. If we are blessed with nervous parents we must put up with them, and we are fain to tolerate any nervous brothers and sisters, not to speak of remoter relatives, whom the laws of heredity have imposed upon us. It is no doubt a very desirable detail in the education of the young to develop their powers of self-control, but whether self-control can ever be cultivated to the extent of overcoming nervousness is a moot question. Nervousness, as we understand it, is a state of undue, and it may be morbid, excitability of the nervous system and though, in truth, it may be induced, the essential, non-acquired form cannot be cured. On the other hand it is equally certain that it can be intensified by injudiciously selected conditions of existence. The author is probably in the right when he points to particular errors of training as in part responsible for nervousness, as, for instance, exposing the growing child to pleasures and sources of excite-

(a) Dr. H. T. Patrick, Journal of the American Medical Association, 1903.
ment in advance of his years and, secondly, the practice of allowing children to associate too much with their elders, a habit which tends to enhance their conception of their importance in the scheme of the universe and deprives them of the salutary influence of an environment better adapted to their years and attainments. Nothing assuredly is as likely to overcome nervousness in the otherwise healthy child as the rough and tumble life of a public school. The fact that in a minority of instances this life has the contrary effect merely proves that the particular subject is unfitted for ordinary work-a-day life and requires special care and attention. The gradually increasing burden thrown upon the young by the unavoidable raising of the minimum standard of knowledge and the consequent deprivation of active outdoor exercise, are doubtless factors in the production of the excessive nervousness lamented by the author. We cannot on this account consent to lower the standard, for that would depress our status in the civilised world; the evil comes in only when the same comparatively high standard is applied indiscriminately to all alike, to the weakening as well as to the intellectually robust. The elimination of the unfit will become more and more necessary as the intellectual requirements of civilised communities become greater; indeed, in many instances the elimination is effected automatically by the victims of this mental hyperalimentation, since they stubbornly refuse to assimilate nourishment which disagrees with them. There may be a minority of children whose digestion is unequal to the strain imposed upon it who yet lack the will power to resist, and these may go under, but this is only another example of a natural law which presses heavily on the weaker members of a community.

THE PROPHYLAXIS OF GONORRHEAL OPHTHALMIA.

A short time ago a discussion took place at the Obstetrical Society of London on gonorrhœal ophthalmia and its preventive treatment. Its general trend was to the effect that routine treatment of some kind was advisable in all cases, but that perhaps the particular treatment recommended by Créde was too strong, and that a milder and more bland antiseptic should be used. This decision did not seem to err on the side of boldness, at least to those who had been accustomed to see Créde's treatment rigorously carried out. A letter has, however, appeared in a contemporary from the facile pen of Professor Japp Sinclair, which places the decision of the Obstetrical Society in quite another light. Professor Sinclair, referring to this discussion and to the rules of the Central Midwives Board, considers the medical profession in England has too often made itself ridiculous, by adopting without criticism German methods, to be able to afford to further stultify itself by insisting upon the routine adoption of Créde's method, even amongst the poorer classes. Dr. Sinclair is always a most interesting and informing writer, whose opinion is received with the respect it deserves, but we fear and hope that in this instance he will not meet with general approval. Laying aside the broad objection referred to above—that nitrate of silver is too strong, Dr. Sinclair objects to Créde's method on several grounds. The first of these is perhaps the result of that runaway—facile pen. Speaking of the enforcing of Créde's method he says, "Poverty is to be the sad qualification for the moral and physical resort. Every poor woman must see her infant start life with unnatural tears and conjunctivitis, and she and the simplest and purest-minded of her female relations must be initiated by an ignorant midwife into the mysterious working of veneral disease." Surely this is not the language to employ in speaking of a practice of preventive medicine, which, even if it has not yet become general in England, has long been the routine treatment at the Rotunda Hospital in Ireland. Professor Sinclair then proceeds to object to Créde's method on the ground that it was unnecessary, that England was not Leipzig, and that the proportion of cases in which intra-par- turient gonorrhœal infection of the newly-born occurred was but too small to render the adoption of so rigorous a procedure as Créde's advisable. This, of course, is an opinion, and when emanating from so high an authority as Professor Sinclair, is entitled to every respect. For ourselves, we should be inclined to question both assumptions, to express a doubt as to whether gonorrhœal infection is so rare, and to disagree in toto with the statement that Créde's method is too "severe." Professor Sinclair brings the statistics of a small annual number of deliveries at the Manchester Maternity Hospital, where Créde's method is not adopted, and contrasts them with the statistics of the Leipzig Frauenklinik, where it is adopted. In answer to this, we quote the following facts as directly to the point. At the Rotunda Hospital, up to in or about the year 1894, Créde's method was not adopted. The then Master did not at that time consider its adoption necessary, because he did not find that gonorrhœal ophthalmia occurred in the hospital. From that date onwards, he changed his mind, and Créde's method was adopted as a routine practice, because the surgeons at the Dublin Eye Hospitals informed him that numerous cases of gonorrhœal ophthalmia were brought to the hospital dispensaries in infants who had been born in the Rotunda Hospital. From the time of the routine adoption of Créde's method, this ceased to be the case. As for the alleged severity of the treatment, undoubtedly a very small proportion of infants suffer for a day or two from a slight catarrh—the result of the silver—but from experience during three years in no case did the writer see an infant leave the hospital the worse for the treatment. Further, the treatment was in almost all cases carried out by a probationer. We confess that we consider that Professor Sinclair could have applied his great powers of criticism with more advantage to other portions of the regulations drawn up by the Central Midwives Board than to the paragraph to which he objects and to the treatment to which that paragraph
lends sanction. How many women lose their lives because of vaginal injections given with unsuitable apparatus? Yet, the regulations say that a midwife shall carry "an appliance for giving vaginal injections"—presumably a Higginson syringe. Would not more explicit directions have been of value? How many patients lose their lives from the routine administration of vaginal douches? Yet the regulations contain no word of condemnation of such a practice. How many patients lose their lives from the use of dirty lubricants by the nurse? Yet the regulations compel a nurse to carry "an antiseptic lubricant for smearing the fingers, catheters, douche nozzles, and enema nozzles before they touch the patient." Once get the regulations free of actively harmful directions and then will come the time for criticizing and amending those that perhaps can be improved. We do not for a moment suggest that Professor Sinclair is responsible for the foregoing insufficient and antiquated directions. If the truth was known, it is probable that it would be found that but for his activity and sacrifice of valuable time, they would have been still more insufficient and out of date. Our point is that it is unwise to censure with exaggerated emphasis at precautions that have been proved to be harmless—even though in some cases unnecessary—when considerable evils still call for remedy.

Notes on Current Topics.

Harvey and the Harveian Oration.

William Harvey was a great man. He cleared away the erroneous views that had been held before him on the question of the circulation of the blood, and he showed on what kind of work progress and truth depend when we are dealing with any scientific matter. Every year he wished an Oration to be given at the College of Physicians in which the past year was to be reviewed, and the names of benefactors mentioned. We find that the Orations have generally been panegyrics of Harvey and his work. His character, scientific and personal, and his reputation have been subjects naturally of great interest to the College. How far his example is being followed now we can leave posterity to judge; and how far scientific work is encouraged by the College it would not be difficult to assess. There is no doubt but that the esteem in which Harvey was held soon after his Royal master's end, and when the narrow-minded, anti-scientific puritans were in power, was not very great. The past year, so far as benefactors to the College are concerned, will not, we think, take long to review. The question that has to be considered is whether it is worth while keeping up the Harveian Oration, for since Harvey lived and taught great changes have come. The College of Physicians has not been left in the enjoyment of imperialism in the matter of licensing for practice. The condition of the medical profession has changed, and the relations in which the College stands towards it are not what they were when Harvey was explaining the circulation of the blood.

Nearly three centuries have gone and England is very different in many ways from what it was then. So far as scientific work is done or encouraged within the walls of the College, we fear little can be said, unless the examining of a large number of second or third class medical students may be regarded as a form of scientific work. The first great change made in the Harveian Oration was, we believe, some forty years ago, when our own language was substituted for Latin, and the Oration was converted from an address almost unintelligible to the audience into something that they could at least follow and comprehend. It is not very clear whether the College owed more to Harvey than he did to the College. What he actually left in his will was enough money to "finish the building which he had begun to erect within the College; and some books and papers, and his best Persian long carpet, his blue satin embroidered cushion, one pair of brass gridirons, with fire-shovel and tongues of brass for the ornament of the meeting room." Whether science was benefited in any way by this legacy is not very clear. Harvey was clever enough to work the College very much in his own interests, and to have impressed the Fellows of his day with strong admiration for him. We think there has been, after all, a tendency to extol, in rather too lofty tones, the work Harvey did. It would be well in those times if the College of Physicians began to reform itself a little and became more sensible and modest than it has been and of more use to science and to the profession than we think it is at present.

The Closed Window Habit.

The indifference manifested by the majority of individuals to the laws of hygiene is seen, perhaps, nowhere more conspicuously than in the habit of occupying living rooms, and worse still, sleeping-apartments, with the windows closed. This general disinclination for fresh air is in part due to the natural aversion to draughts and also to the trouble involved in opening many windows, the frames of which are often heavy and cumbrous. In many houses one is informed with the greatest unconcern that such and such a window is never opened under any circumstances or that it "is not made to open." Meals are partaken of in these rooms and the health-conscious of the occupier is quite satisfied if the door remain open for a short time afterwards. Again, at night-time the windows are almost superstitiously closed in bedrooms, even when from the position of the bed there could be no possibility whatever of a draught. The belief in the poisonous quality of the night-air is still held by a large number of people who would scorn to be told that they are superstitious in other matters. We have walked down suburban streets at a time when the majority of inmates are asleep, and even on a hot summer's night it was found to be quite the exception for the windows in the upper storeys to be open. This willful prevention of the circulation of fresh outside air in living and sleeping rooms is largely responsible for the unrefreshed sleep, the sallowness of complexion, the increasing nervousness, and the liability to catch cold which
are commonly seen among town dwellers, and, indeed, we are sorry to say that the pernicious habit also pervades country-folk. A family goes away for a month's holiday to the seaside or to a farm-house. The children frolic on the sands or in the fields for ten hours or so a day. When they go indoors they have meals in close apartments and often sleep two or three in a room with the windows tightly closed, thus undoing all the good they have received during the day-time. If the modern dwelling-house be up to date with regard to its sanitary arrangements, why should not the ventilation be proportionately modernised? We look for the time when architects will see the need for reform in window-construction and when parents and householders will realise their responsibility towards themselves and their children in this matter.

Holbein's Swim.

Holbein has failed again. After another of his plucky and determined efforts, he has had to confess the task he set himself too severe. Cui bono? is the question that naturally suggests itself—what purpose do these great tests subserve? We expect to see some head-shaking and hear some solemn warnings from some of our contemporaries as to the folly and danger of these feats of endurance. The strain of the prolonged immersion, and the unceasing activity of the voluntary musculature extending over seventeen hours, is undoubtedly a severe trial even to a man in the prime of life and the peak of condition. It seems to us, however, that the question turns not only on a uniform hypertrophy of the muscles, but on an adaptation of the more important viscera to the call made on them. The two organs that are taxed most severely are the heart and the lungs, and if there be hypertrophy of the heart that can cope with any reasonable demand, and an increase of vital capacity that can maintain a reasonable exchange of oxygen and carbonic acid (we mean, of course, reasonable under the circumstances), the result turns chiefly on muscular strength and moral stamina. Where the mischief is chiefly wrought in the constitutions of the athletic is in a comparative over-training of the muscular system without concurrent changes in the vital organs. But even this risk is greatly exaggerated, chiefly owing to the rather sweeping generalisations of the late Sir Benjamin Richardson. The studies of Morgan in this country on the oarsmen in the Oxford and Cambridge races for forty years, and of Bradford in America on the Harvard crews, although the numbers were not large in either case, both gave the athlete a greater expectation of life than the life table, and in neither case in the years investigated was any medical selection or supervision exercised. Training and athleticism both eliminate the unfit, and if these be rejected, as they ought to be, by careful medical examination before being subjected to the trials of endurance involved, the risk of constitutional damage is probably small, especially if compared with the enormous physical benefits that hard exercise confers on the organism. If we are to have our athletics we must have our protagonists to set examples and stimulate emulation, and Holbein's efforts will have no other result than to lend greater interest to the art of swimming and the habit of endurance. When the Channel traffic is seriously inconmoded by the number of his emulators we may reconsider the position.

The Noeology of Chorea.

One by one the old landmarks are shifted, the cards are shuffled, a turn given to the kaleidoscope. The old friends of our student days take on new guises, and bob up in the most unexpected places. If we glance through the text-books of our youth we find the section of nervous diseases has suffered wholesale depletion. All to the benefit of our knowledge, however. Is chorea to follow tetanus, meningitis, and Grave's disease? It seems practically certain that it will, and if the new pathology be the true pathology we shall be greatly the gainers by the new conception that we shall form of its nature. The scrappy morbid anatomy and unconvincing theories of its pathology will give place to a definite, consistent idea of the sequence of events in the choreic child. Poynton's micrococcus of rheumatic fever has been found by himself and others in the pia mater and brain in fatal cases of chorea, and has even been isolated from the cerebro-spinal fluid and cerebral tissues under similar circumstances. The lesions of fatal acute chorea are consistent with a theory of infection, and the intra-venous injection of the micro-organism into rabbits has produced choreiform movements. The clinical association of chorea and rheumatism has long been noted and insisted on, and, if the same micro-organism be the proximate causal factor of both, the pathological identity of the diseases will be strongly homologated by their well-known morbid manifestations in children. The treatment founded on these data will naturally differ from the old, and already Dr. Lees speaks of encouraging results in chorea with large doses of the salicylates and bicarbonate of soda. We must wait before embracing too eagerly this new pathological infant, but we can at any rate give it a warm welcome and a hearty assurance of criticism. If in the fulness of time it be found to justify its existence, the transference of chorea from the nervous diseases to the category of cerebral rheumatism will be subject for congratulation for us, our patients, and Dr. Poynton.

Operating Under Difficulties.

There is obviously no reason why the general practitioner should not perform many of the minor operations in surgery which come under his care. If his results are not altogether as good as those of the professied surgeon it is in great measure due to the fact that he is apt to undertake what he considers simple operations without adequate assistance. We have known many instances in which practitioners have themselves given chloroform and curetted, or digitally explored, the uterus, with, at most, the assistance of a nurse. Is it surprising
if, hampered by the unnecessary difficulties thus imported into the procedure, he fails to accomplish it satisfactorily? To curette properly requires at least one, if not two, assistants in addition to the anaesthetist. The same remark applies to the removal of post-pharyngeal adenoids. With adequate assistance—two assistants and the anaesthetist—the operation is one which presents little difficulty in the hands of one not wholly inexperienced. Without such assistance it may be simply impossible of achievement. Again, to attempt tracheotomy single-handed, unless absolutely constrained thereto, is to court disaster. The plan to go upon is to provide at least as much facility for performing the operation as would a specialist in that department, for even then the balance is in favour of the latter, given his greater experience and superior dexterity. There are, of course, circumstances in which it may be impossible to follow this advice, but though this fact may excuse failure it does not make for success.

A Homœopathic View of Serumtherapy.
The current number of the Homœopathic Review contains an article on serum therapeutics in their relation to the law of similars, the ostensible object of which is to prove that this method of treatment is in reality a further application of the homœopathic principle. The arguments advanced are striking examples of special, we might say of specious, pleading. In one of the tables a parallelism is sought to be established between the action of arsenic in regard to eczema and that of antitoxin in diphtheria. The author starts with the assumption that in toxic doses arsenic produces eczema, an assumption which finds no support in any textbook of toxicology or diseases of the skin, the eruption thus induced being usually of the dry, desquamative kind. A further assumption is that when administered therapeutically in minute doses arsenic causes the production of an antitoxin which cures eczema, another scientific heresy, since arsenic is universally recognised to be useless in eruptions of the eczematous class. To compare this faulty sequence with the action of diphtheria virus in producing antitoxin, and the action of the latter in antagonising or curing diphtheria, is to challenge an imputation of ignorance or downright bad faith. Moreover, we have never before seen it advanced that the utilisation of the products of morbid action for purposes of immunisation or cure was in accordance with homœopathic principles, for it is absolutely and essentially distinct from the view that remedies which in large doses induce certain symptoms are curative of those very symptoms when given in much smaller doses. We regard the article, indeed, as an attempt to obtain credit under false pretences.

Sulphur in Illuminating Gas.
The indescribable "something" in the air of large towns which can be instantly detected by those coming from the country with a keen olfactory sense is by no means altogether due to the amount of carbonic acid contained therein. There is another product of combustion which is not derived from human beings—viz., sulphur, to which many of the objectionable properties of town air may be ascribed. Dr. J. S. Haldane, writing from the physiological laboratory at Oxford in the Journal of Hygiene, believes that sulphur is responsible for the chief, if not the whole, of the unpleasantness which is experienced in air vitiated by ordinary lighting-gas. On passing a stream of carbon bisulphide through a gas-burner in regulated amounts it was found that the irritating properties of the gas were increased in direct proportion to the quantity of sulphur thus set free in the atmosphere. At certain times the natural gas contained considerably more sulphur than at others with a result which was quite appreciable to those who breathed the air. As a rule, the amount of sulphur in illuminating gas is limited by the gas companies to about twenty grains per 100 cubic feet. Frequently, however, this quantity is exceeded, and when this is the case it becomes noticeable as fog. It is not, of course, implied that the vapour of a typical London fog is entirely due to sulphur, but it may be observed at such times that the blackening effect of the atmosphere upon the precious metals is more obvious than when the air is clear. A special difficulty appears to lie in the way of permitting gas from his deleterious element, but in the interests of the public health it is to be hoped that a practical solution may be forthcoming.

Lemons in Purpura Haemorrhagica.
The astringent properties of the lemon and its power in arresting haemorrhage from the lungs are much dilated upon in the popular text-books of "domestic medicine." At the same time, it is within the knowledge of almost every medical man that this fruit, when sucked in the raw state, has succeeded in preventing the onset of an attack of haemoptysis, or, at any rate, warded it off until the "dreaded hours of night" have passed. In some of the more severe varieties of purpura, the powers of the physician are often taxed to the utmost. Turpentine, ergot, adrenalin, and the mineral acids may have all been tried and yet in vain. It is encouraging, therefore, to learn that Pick, of Vienna, has successfully treated fifty cases of purpura haemorrhagica with lemons, a little arsenic in the shape of Fowler’s solution or aspirin being also given in two of them. Six to ten lemons a day were administered, and no ill-effects were noticed, except that in the larger quantities they produced a mild purgation. Two of the cases had developed in connection with malaria, and it is interesting to note that in the Roman campagna stewed lemons form a popular remedy against the disease, the fruit being sliced with the peel, and the filtrate taken by the tablespoonful. The lemon juice appeared to act promptly, though two of the cases of purpura were very severe. Hitherto the employment of the lemon in purpura has been chiefly confined to those cases in which there is also a scorbutic element, and here, together with lime juice, it has met with great success. When scurvy is out of the question it cannot be the anti-scorbutic properties of the
lemon which give it its efficacy, but rather some astringent principle which acts directly upon the vessels.

The Tsetse Fly and Sleeping Sickness.
The tsetse fly has long been known as one of the great obstacles in the way of the civilisation of Central Africa, on account of the effect which its bite produces on horses and cattle. A fresh indictment has now been drawn up against it, by M. E. Brumpt of the Bourg de Bozas Mission, who believes that it is the vehicle by which the organism of sleeping sickness is introduced into the human body. M. Brumpt draws attention to the coincidence between the geographical distribution of sleeping sickness and that of the tsetse fly. Apparently in all districts where the disease exists the fly is found, and where the fly is found the disease easily aclimatises itself. There are, of course, many districts in which the fly is found and in which sleeping sickness is absent, but this is easily explained by the obvious fact that the tsetse fly must be first infected before it can distribute the disease, and that in many districts infection has not occurred. M. Brumpt relates a striking case in proof of his theory. The tsetse fly lives principally along the borders of rivers, and sleeping sickness is much more frequent in people living in such places than in those who live inland. At Banamia, a small town close to the banks of the Congo, there was in one village a settlement of 3,000 fishermen, and near them a settlement of cultivators who very rarely went on the river. At the present time the fishermen have been reduced to 300 in number by sleeping sickness, whilst cases of the disease are very rare amongst the cultivators.

Laughter in Disease.
Considering the intricacy of the nervous mechanism involved in the muscular movements concerned in the manifestation of the different emotional expressions it is not surprising to find that these may be modified in a great number of ways in disease. The well-known observation of Duchenne, that in paralysis of both facial nerves the patient seems to "laugh behind a mask," illustrates well the fact that in this condition the motor contrivances are powerless to call forth the desired contractions, although the feeling of amusement may be intense. A slight change of colour may be all that is perceptible to the observer. The most common morbid form of laughter is, perhaps, that known as the "risus sardonicus," which is due to the tonic contraction of the risorius muscle which gives rise to the peculiar strained expression seen in tetanus and also in other forms of painful disease. The risorius is not used in pleasurable laughter, the zygomaticus major being employed for that purpose. In the various mental conditions characterised by loss of control, irregular, constant, or immoderate laughter is sometimes a symptom. Every anaesthetist can recall instances in which the effect of the inhalation of chloroform or ether provokes laughter, either in the stage of excitement or when the patient comes round after the operation is over.

As the normal physiology of the emotions is anything but simple, so their pathology, when disordered, is most subtle. As M. Raulin has pointed out, it may be that there is a physiological reason for laughter analogous to yawning, so that its appearance in disease is not altogether to be disregarded.

Changes in the Nervous System in Plumbism.
The toxic effects of lead upon nervous tissues has been known for a long period, but there have been comparatively few opportunities of determining the exact nature of the histological and pathological changes met with in the nervous system in fatal cases of plumbism. The investigations of Dr. Spiller, neurologist to the Philadelphia Hospital, published in the Journal of Medical Research, form an important contribution towards our knowledge of the subject; in a post-mortem examination upon a man, aged 48, who had suffered from lead-poisoning with paralysis, he was found that the endothelial cells were proliferated in several places on the outer surface of the pia mater, especially on the inner organ of the cortex. The nerve cells of the anterior horns of the cervical and lumbar regions of the spinal cord were intensely degenerated, as shown by sections prepared by Marchi's method. The median nerve also presented considerable degeneration. Sections of the prontor radii teres muscle showed an appearance resembling interstitial myositis, while the nerve-bundles within the muscle were degenerated. There was also noticed a proliferation of the endothelial cells of the capsule of the lumbar spinal ganglia, which Dr. Spiller points out resembles the condition seen in rabies. No lead was actually recovered from the brain substance, but this does not negative in any way the diagnosis of the case, as it has been shown by Quensel that lead probably affects the brain indirectly through the blood. Whether the poison acts first upon the peripheral motor nerve-fibres or upon the anterior cornual cells is not known, but as both these are ultimately affected, the question becomes one of secondary importance.

Typhoid Fever.
The question of the treatment of typhoid fever is perennial. We have seen the different methods advocated tested and disregarded. Tartar emetic has in some hands given unusually good effects, especially in India, and the older journals and records tell of good results from bleeding. Murchison trusted to dilute hydrochloric acid, and his classic work shows unusual success in the treatment. Pure phenol was not less helpful in other hands. Then came the search for intestinal antiseptics, and benzene and the sulphocarbonate were recommended on scientific grounds. Now the medical fashion changed to antipyretics—the truly scientific treatment, lessening tissue waste and quieting the abnormal action of the heart. Quinine and a number of synthetic remedies were introduced; bathing, douching,
and so forth were now lauded for their wonderfully good effects. We do not decry drugs in the treatment of typhoid fever or any other disease; but we think more attention should be paid to their selection and action. The synthetic anti-pyretics did a great deal of harm in their day, as physicians came in time to learn, and to-day the prescriber is in no hurry to run down temperature by drugs of which he too often is ignorant, neither does he expect that antiseptics will alter the secretions; he recognises that until the intestinal mucous membrane resumes its normal function the secretions will, in spite of antiseptics, be septic. Some unpleasant results followed the cold bath treatment. The effect on the dilated peripheral vessels of the cold water was not always beneficial. Even before emersion the patient was too often terrified by the idea of a cold bath. We refer to these things because we think that in typhoid rest is the essential, supplemented when necessary by drugs, or sponging with water at a temperature of not less than 70° F. Of drugs we know of none better than Murchison’s dilute hydrochloric acid mixture. We are led to make these observations by reading in the druggists’ circulars the many panaceas for the disease, each firm urging with the importunity of the commended widow its own specialty.

Medical Fees and the Poor.

In a letter to a lay contemporary Dr. L. Kidd, President of the Irish Medical Association, puts forward a scheme by which the poor of the different unions throughout the country may obtain medical advice and medicine at rates which would not unduly tax the purse of any not eligible for Poor Law medical relief. He suggests that tickets be issued by wardens and relieving officers and others entitled to grant Poor Law medical relief. The price of the visit and medicine to a holder of the ticket, for the first visit not to exceed 5s., and 3s. 6d. for each succeeding visit during that sickness. The patient would be free to select his own medical attendant. All fees to be paid in advance. Consultations in the doctor’s study 3s. 6d. each, if the valuation of the patient’s property exceeded £5 and was under £10, and 2s. 6d. where the valuation is under £5. The scheme has the advantage of refuting the statement that Irish practitioners charge such high fees that the poor are driven to seek Poor Law medical relief, and so far is worthy of support. But we do not see what arrangements can be made about providing drugs. Fellows of either the Physicians or Surgeons cannot supply drugs under such conditions, and if arrangements are made to have a pharmaceutical chemist to supply them, what is to prevent the patient having the bottle repeated as 1s. or 1s. 6d. by the pharmaceutical chemist as often as necessary after the first visit. But why exact a ticket at all? If a small farmer calls to consult the practitioner why not see him and accept his 2s. 6d. or 3s. 6d. as the case may be.

A man who is paying a fee, small or large, objects to come forward in forma pauperis. The similarity of the procedure in Dr. Kidd’s scheme too closely resembles the ticket system of the Medical Charities Act to become acceptable. We would suggest that from the poor fees, proportionate to the valuation of their holdings, be accepted by all members of the medical profession, Fellows and Licentiates, who are willing to do so, and that the Colleges raise no objection to their Fellows providing medicines. By so doing the poor would have an opportunity of consulting a medical practitioner and be saved the risk of the pharmaceutical chemists’ prescription.

Oberst’s Anaesthesia.

Although it is more than twelve years since Oberst’s method of producing local anaesthesia was first published, it has never received in these countries the amount of attention it deserves. The method must be clearly distinguished from Schleich’s—the commonly practised method of infiltration. In the latter the terminal nerve-twig is anaesthetised by the direct injection of cocaine solution into the operation area itself; in the former, the circulation being stopped, the nerve trunks themselves are paralysed by cocaine injected around them, producing anaesthesia of the entire extremity. Mr. Struthers, of Leith, calls the attention of surgeons to its advantages in a recent article. (a) He has used it in some fifty cases recently, and found it very useful in all operations on the digits—amputations, removals of nails, operation on whitlows, &c., as well as in operations on the penis. He does not advise the attempt to perform operations on other parts by this method, owing to the difficulty of producing sufficient anaesthesia without injecting the solution into the large nerve trunk itself. Eucaine-B. may be substituted for cocaine.

Aspiration Made Easy.

The occasions on which the average practitioner is called upon to withdraw pleural or other effusions by aspiration are comparatively rare, with the result that when it comes to the pinch it often happens that the air syringe does not work and serious inconvenience is caused. In view of the importance of carrying through the operation smoothly and completely we welcome an ingenious device described by Dr. Kari Connell, (b) for obtaining the necessary vacuum. He takes a strong clear glass bottle of large size, say about five pints, duly fitted with a perforated rubber or other tightly-fitting stopper to which is attached a short length of firm rubber tubing, clamped by a hemostatic forceps or clamp. Into this he pours three drachms of rectified spirit, which is made to moisten the entire inner surface of the bottle, the excess of alcohol being poured off. It is then placed upright and the layer of alcohol ignited. A sheet of flame descends into the bottle and when the flame touches the bottom the stopper is quickly placed in position, and it only remains to attach the tube to the aspirator. Thus prepared the bottle will with-
draw from sixty to sixty-eight ounces of fluid, a quantity far in excess of probable requirements. The suction power is limited by the collapsing index of the tubing, so that the less resisting the tube the gentler is the aspirating force. Moreover, the force can be regulated easily enough by a screw clamp applied to the tubing.

Mountain Tubular Railways.

The project to construct a tubular corkscrew railway to the summit of Mont Blanc strikes one almost as an outrage. In cities, where surface traction is practically impossible to the necessary degree, it may be excusable if people prefer to run certain risks in order to arrive promptly at their destinations, but the charm of mountain climbing lies in the very act of climbing, or, at any rate, in the panorama which unfolds itself as one mounts higher and higher. One has only to figure the different appearance of the traveller who has attained the summit of such a mountain as the Righi on foot, with his bright eyes and healthy complexion, with that of the train traveller who alights, shivering as if suffering from ague, consequent upon his brusque transference from the hot plain to the frozen heights, to grasp the folly of mechanical transport, which is shorn of the exhilaration which ought in due course to follow an ascension. There is no particular object in attaining altitudes beyond the chance of contracting the mal de montagnes, unless it be the magnificent exercise which these excursions provide, and to burrow upwards in a tube may constitute a splendid engineering achievement, but is simply absurd viewed from the mountaineer's point of view.

Varicella and Variola.

It is odd that the identity of these two diseases should have received the support of two such experts as Hebra and Kaposi. The fact, however, that children recovering from chicken-pox have developed small-pox, and vice versa, is conclusive proof of their being distinct morbid entities. In fact, the diagnosis of an eruption of doubtful nature will be greatly facilitated by observing whether the subject has been efficiently and recently vaccinated, small-pox being extremely rare under such conditions, while vaccination has no protective influence against chicken-pox. An interesting epidemic occurred in 1900 at the Philadelphia Municipal Hospital in which a child admitted to a small-pox ward under a mistaken diagnosis infected thirty-three of the variolous patients with chicken-pox, although the child, having been promptly vaccinated, did not herself contract small-pox. An interesting point is, that in some cases the secondary infection did not take place for a month, a fact which suggests that persons in the early eruptive stage of small-pox are not amenable to the infection of chicken-pox.

Chloroform-preserved Vaccine.

The length of time—several weeks—which must elapse before glycerinated vaccine can be regarded as free from extraneous bacteria entails not only delay but also some impairment of the activity of the product, the potency of some vaccines, glycerinated and otherwise, becoming greatly impaired within a few weeks of collection, that is to say, within the period of time required for the glycerine to exert its bactericidal properties. Dr. A. B. Green has discovered that by using a one in two hundred aqueous solution of chloroform the purification of the vaccine can be effected within a few hours of its collection, a circumstance of considerable importance, not only in respect of the saving of time when the demand is great, as in times of epidemic, but also in that it enables the vaccine to be employed at a date approximating its period of maximum activity. The process may, moreover, assist in preserving vaccine active in hot climates where as a rule, it rapidly deteriorates.

Anesthetic Pyrotechnics.

A New York surgeon records the fact that, while engaged in an operation on the eye in a patient under ether he had occasion to bring the electric light close to the face, whereupon an explosion took place which singed the patient's face and created some apprehension. Curiously enough he was unable to reproduce the phenomenon, although he tried on several occasions. Nevertheless, the fact that it did occur suggests the wisdom of avoiding the close proximity, even of closed lights, when ether is the anaesthetic employed. Our readers are probably familiar with the fact that chloroform vapour, when allowed to come into contact with an open gas flame, undergoes decomposition with the production of an extremely irritating gas, which has on at least one occasion caused death from acute bronchitis.

Special Correspondence.

[FROM OUR SPECIAL CORRESPONDENTS.]

GLASGOW.

Glasgow University Extension.—Some time ago the University authorities agreed to the extension of the college buildings according to plans submitted by Mr. Miller, architect, which preserved the students' recreation grounds to the west of the existing buildings, but unfortunately necessitating them being separated, and therefore materialily interfering with the symmetry and compactness of the whole. The architect had prepared an alternative plan which required the sacrifice of the recreation grounds for building purposes. Since then there has been some newspaper correspondence on the subject, including a letter from Dr. David C. McVail, a member of the University Court, commenting severely on the plans adopted, and strongly and therefore materially interfering with the symmetry and compactness of the whole. The architect had prepared an alternative plan which required the sacrifice of the recreation grounds for building purposes. These would form part of a quadrangle, which would allow of any further extension of the buildings as necessity and time might demand, while preserving the external appearance of what would be a most imposing and commanding range of buildings. With the facilities now offered for getting beyond the city boundaries by tramcar or by railway, it is thought there would be no great hardship inflicted on the students, if any at all, in the removal of their recreation ground a few miles off. A meeting of the University Court has been called by the Principal for the consideration of the whole subject, when it is generally expected that the alternative plans will be adopted, and certainly this seems very desirable.
AN AGED DOCTOR IN ACTIVE PRACTICE.—A few days ago, John Burns, surgeon, Fitzroy Place, Glasgow, entered upon his eighty-ninth year. He is still quite actively engaged in professional work. Tall and perfectly proportioned, he carries his years surprising well. A sufferer from a bank failure many years ago, he required at the age of 63 to make a fresh start in life. That he did manfully, and has probably again succeeded in gaining the competency for his declining years, although from his healthy appearance he may be spared for many years to come.

GLASGOW PARISH COUNCIL AND ITS MEDICAL OFFICER.—At a meeting the other day, Mr. Haddon, a member of the parish council, expressed his views on the subject of the "poor in the North". For some years the subject has been in the public mind, and the last few weeks it has attained great prominence owing to the proposal of the Glasgow City Council to provide a public hospital for consumptives in the new city. As reported in the column last week, the proposal raised a storm of opposition in the district round the park, a storm which some of the local medical men dreaded, and others tried to subdue. The proposal was discussed by the Corporation last week, and after a heated discussion was rejected by 21 votes to 16. The chief ground of opposition was the fear of infection if a number of consumptives were gathered together close to where the children of the neighbourhood play. The question of infection is a doubtful one, and a stronger grounds of opposition may be found. No doubt it looks well at first sight to see the anxiety of the Public Health Committee to provide for poor consumptives; but a little study of the question rather inclines one to the view that they are seeking a cheap and easy way of passing off the attention of the ratepayers from their past and present neglect of the matter, which gravely affect the general health of the population, and have at least a share in causing the present high death rate from consumption. This is not a lightly made statement, but one resting on careful study of the facts. The deaths from pulmonary phthisis registered in Belfast last year were over 1,100, while Liverpool, a town situated as Belfast in many respects, had only a little over 1,300 deaths. Here is a plain fact that year by year increasing the chance of contraction of the disease. Moreover, diseases of the respiratory system account for over 1,000 deaths, and many of these are not death due to tuberculosis. Add to these the deaths from the fearfully common tuberculosis diseases of bones, &c., and one may safely put the annual deaths from tuberculosis in Belfast at 2,200. Allowing 70 years life to each patient afflicted with tuberculosis, we should have above 6,000 persons suffering from these diseases at any one time in the city. A few—say one in twenty—of these may be in affluent circumstances, and able to get change of air, &c. A few more—say five or six in twenty—may be in competent circumstances, &c., and a great majority will be indigent, and if tubercle is to be stamped out, or even materially lessened, provision must be made for the proper isolation of these patients and the disinfection of their homes. To begin to treat twenty of them in a public park is simply ludicrous, unless a carefully prepared scheme for the treatment of 2,000, and not 20, is at present ready, including the provision of the necessary money. Such a scheme, should be prepared by the Board of Guardians and their advisors, and the Public Health Committee should attend to their proper business, that is, looking after the state of the city generally in all matters affecting public health. It is notorious that in this they have been guilty of neglect.

Take four points only—(1) Our drainage system is wretched, and till that expensive failure, "the main drainage system," is properly cleaned, we cannot expect the city to be healthy. (2) Nothing worth speaking of has been done to prevent the periodic flooding of large districts of the city. Each flood must sow the seeds of disease and death broad-cast, and vigorous measures are required to prevent these floods. They will not be prevented or their harm neutralized by a flood of talk in the Town Hall. (3) Jerry building is rampant in Belfast—but it would perhaps be too much to expect that the members of the Corporation should put a stop to this, and so destroy the means of gain for a living of many of their own number. (4) Ample powers are in the hands of the Public Health Committee to order the proper inspection of mills and factories, and periodical cleansing and disinfection of them—but such powers are never used as far as is known. It is earnestly to be hoped that the citizens of Belfast will not allow themselves to be deceived, but will force their representatives to attend to these and other matters, the neglect of which causes our city to be a disgrace to an intelligent population.

THE INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

AMONG the contributions on the subject of tuberculosis to the International Conference on Hygiene held last week in Brussels was one by Dr. Newsom, Medical Health Officer for Brighton, who described the action of English public health authorities in the struggle against tuberculosis. He showed that the mortality from this disease had been divided by two, and regarded the greater decline at earlier ages and in the female sex as indicating that domestic causes of tuberculosis have improved more than occupational, to which men are particularly exposed. Omitting the earlier years, for which the figures were not entirely trustworthy, the rapid decline was due to the immediate following active sanitary legislation and administration. He considered that very important sanitary improvements had acted directly by diminishing opportunities of infection, and indirectly by improving the standard of health, but that the most good would be secured by controlling to the utmost both sets of factors. The close relationship between the price of wheat and the mortality from consumption was not simply a question of cheaper food, but of a general improvement in the standard of life. Poverty and tuberculosis were "close companions, poverty not only furnishing the appropriate soil, but making present the dangerous opportunity of infection." As regards administrative measures against tuberculosis, the first was a knowledge of the existence of the disease. Facilities for the treatment of cases had been largely utilised in Brighton since 1857, and that town had a system of voluntary notification of cases in successful working since the beginning of 1899. Sheffield had recently secured a local Act enforcing compulsory notification of all cases, and powers for disinfection and cleansing. The procedure in connection with notified cases was described, this not involving any hardship to patients. Special stress was laid on the hospital training and treatment of consumptive patients. In Brighton ten beds were reserved at the isolation hospital for such patients. Here patients
were kept for a month, 120 patients being thus annually passed through the institution. The patient himself, though not cured, was improved in health, and able to stand more again with increased strength. While in the hospital his home was cleansed and disinfected, and when he went home he had been so trained in managing his expectancy that in the majority of cases the danger of infection for his family and fellow-workers had become very slight. It was urged that the educational part of sanatorium treatment, as thus developed, was more important than its curative aspect; and it presented the advantage that a much larger portion of phthisical patients could leave their work for a month than for more protracted periods. In this connection stress was laid on a remark made by Dr. Koch in his address at the meeting of the British Congress on Tuberculosis. He expressed the opinion that the great reduction in the mortality from phthisis in England was due to "the considerable number of special hospitals for tuberculosis" in that country. The number of beds in these hospitals given by Dr. Neuwahlom showed that they cannot have had more than an infinitesimal effect. If, however, workhouse infirmaries were taken into account, the result was very different. In Brighton 201 consumptive patients admitted to its infirmary spent on an average 316 days there before their death. This means that 18 per cent. of the total consumptive patients in Brighton were, so far as their relatives were concerned, living the most infectious period of their lives under conditions in which freedom from infection was secured. This factor must have had a large share in the causation of the reduction of phthisis in England.

Dr. J. F. Sykes, Medical Officer of Health for St. Pancras, presented a paper showing that the death-rate in England and Prussia (the population and rate of increase in both countries being approximately the same) from tuberculous diseases had decreased from 36 to 15 per 1000 of both sexes in the period between 1851 and 1901.

The several European representatives also described the measures taken in their respective countries to combat the disease.

On the 3rd inst., the following resolution was passed on the motion of Sir Patrick Manson:

"That this Congress, recognising the practical importance of the mosquito malaria theory, would urge on all Governments in malarial countries (1) that officials, both civil and military, be required, before taking service in such countries, to show evidence of practical knowledge of the theory and its application; (2) that international agreements be entered into concerning the closing of the opening, whether mental, missionary, or other, in such countries be requested to include in their curriculum instruction of native students in the mosquito malaria theory and its practical application; (3) that officials ignorant of the theory or systematically ignoring its practical application be considered as unsuitable for service in malarial countries."

Dr. Martin, of the Pasteur Institute of Paris, read an interesting paper on the results obtained by sero-therapeutic processes in the cure of infantile diphtheria. The paper was the subject of a long discussion.

The sixth and seventh sections met to discuss means for combating plague. It was agreed that the quarantine imposed on persons coming from countries infected with bubonic plague should be freed of its vexatious character, and that the evil could be combated more efficaciously by the institution of suitable sanitary services on board ships, and by general international measures against the means by which plague was spread, including the extermination of rats likely to be infected.

The meeting on September 5th was principally devoted to a discussion of the precautions to be taken to check the spread of tuberculosis.

Dr. Dejong, professor at Leyden University, delivered an address, in which he gave reasons for believing that bovine tuberculosis was transmissible to human beings. The bacilli of human and bovine tuberculosis were identical in their effects, and consequently it was the duty of the public authorities to prevent the propagation of tuberculosis by unsound meat and infected milk. Dr. Grazi, of Brussels, said that proof had now been given that human tuberculosis was transmissible to cattle. The converse experiment—that is, the transmission of bovine tuberculosis to human—could not be made. Dr. Grazi, of Brussels, declared that he had performed a similar experiment on sixteen monkeys by giving them the milk of tuberculous cows to drink, and fourteen of the animals died. He also reported that he had not made with regard to infantile tuberculosis.

The debate resolved itself largely into a controversy between the French and Belgian delegates on the one hand and the Germans on the other. The former supported the thesis of the transmissibility of bovine tuberculosis to human beings. The Germans contended that such transmissibility had not been proved.

Eventually the sections by a large majority passed the following resolution: "That human tuberculosis is perfectly transmissible from one person to another, and that in the present state of knowledge, it is necessary to recommend hygienic measures for the prevention of the propagation of animal tuberculosis in the human species."

Correspondence.

EMPYEMA AND SINUSITIS OF THE ANTRUM.

To the Editor of The Medical Press and Circular.

Sir,—The etiology of empyema of the antrum is often obscure, and if any simple means could be devised whereby a differential diagnosis might be made between the various pathological conditions which present themselves, having as their chief symptom secretion or the collection of pus in the cavity to step in advance as regards treatment would not doubt be achieved. The aid to diagnosis suggested by Dr. Mau (quoted in your issue of to-day, September 2nd) does not, however, seem very practical, if, indeed, it is based upon actual experiment. It is only in very exceptional cases of empyema that the ostium—that the natural opening into the nose—is so obstructed as to be impervious to fluid. As soon, therefore, as injected fluid reached the level of the ostium, with instant flow out, and it would be impossible to fill the antrum or to measure its capacity by the method suggested. In conjunction with my partner, Mr. England, I have during the past fifteen years tapped the antrum for empyema and constructed drainage apparatus in a very large number of cases. With very rare exceptions all these cases have been sent to us by surgeons by whom the diagnosis had been made, and under whose care with our co-operation the cases have remained. My experience would lead me to doubt whether in any considerable number of instances a distinction can be really drawn between empyema and sinusitid. I should rather say that these terms are as a rule mere synonyms.

I am, Sir, yours truly.

Henry Sewill.  
Cavendish Square, September 2nd, 1903.

THE PRECANCEROUS STAGE.

To the Editor of The Medical Press and Circular.

Sir,—There have been many suggestions made of late as to the cause or causes of cancer. We have also had many suggested therapeutic remedies. Reference has been made from time to time to a precancerous stage. After examining very many sections of cancerous tissue, and after watching very many cases, I have come to the conclusion that the precancerous stage is of inflammatory nature. How far this is
recognised I know not, but I am confident that if this view were more generally recognised we should hear of fewer cases of inoperable cancer, and fewer patients would succumb to this dread disease. The innocent ulcer of the lip, the innocent chronic mastitis, the neglected constipation and irritation of the bowel mucosa with ulceration, then malignant ulceration, and the lingual ulcer are all suggestive examples of my contention.

I am, Sir, yours truly,

A CORRESPONDENT.

THE FINSEN LIGHT TREATMENT OF LUPUS.

To the Editor of The Medical Press and Circular.

Sir,—In the last issue of your journal, a paragraph appears referring to a suggestion by the Cooteshill Board of Guardians that an Institution be established in Dublin for the treatment of lupus by the "Finsen Light."

While recognising to the fullest, as we do, the spirit of Christian charity which actuated the Chairman and Board in bringing an urgent matter so clearly under public notice, we may be permitted to say, on behalf of the Governors of the City Hospital for Diseases of the Skin, that the first installation in Ireland of the "Finsen Light" was established in connection with this Hospital in 1901; fully equipped and working steadily ever since, during which time numerous cases have been treated and cured, including some admitted on the recommendation of Poor-law Unions and County Councils throughout the provinces.

Jealous of the good name of the hospital, the only heritage it possesses, and conscious of the very excellent work which it is doing among the most afflicted of our sick poor, nevertheless we are forced to acknowledge that its sphere of utility could be still further materially developed if a larger measure of financial support were extended to it.

The installation of the "Finsen Light" and its yearly upkeep are an additional heavy strain on the resources of the hospital, and the shoulder load which the Governors have to bear may be fairly imagined when we state that during last year more than 5,000 attendances were registered from all parts of the county (to whom medicine and medical advice were administered gratis), including patients recommended for this special treatment.

In order to meet the increasing demand for admission of patients, the Managing Committee are at present busily engaged in preparing and equipping larger and more centrally situated hospital premises in the best part of Great Brunswick, which they hope to have quite ready next month.

Applications for admission to the light treatment should be addressed to the Hon. Sec. at the hospital, and in each case accompanied by a doctor's certificate of suitability.

We may mention that, with the exception of a small annual grant from the Dublin Corporation, the hospital is entirely dependent on voluntary contributions. It is open free to the poor of all denominations, and is nonsectarian in the fullest sense of the term.

On behalf of the Governors.

We are, Sir, yours faithfully,

ALD. WM. IRELAND, J.P., Governor.
C. M. O'BRIEN, M.D., Governor.

A MEMBER of the London and Counties Medical Protection Society was, some time back, arrested by the Japanese police on board ship by mistake, for an individual of the same name. As a result of representations made by the society to the Foreign Office, the Japanese Government has now decided that, while maintaining that the claim for compensation could not be entertained in accordance with the law of the country, they will grant the complainant, as a matter of courtesy and grace, the sum of £30, in view of the annoyance and inconvenience to which he has been put.

Medical News.

Opening of the Medical Schools.

Most of the medical schools in connection with the London hospitals will re-open for the winter session on October 1st. At Charing Cross Hospital an introductory address will be delivered by Sir Charles Wyndham; and at King's College Sir J. A. Cockburn, K.C.M.G., will lecture before the students on "Imperial Federation and its Physiological Parallels."

Mr. Justice Wills has consented to preside at the Middlesex Hospital; Miss Pace, M.D., will give the address at the London (Royal Free Hospital) School of Medicine for Women; and Dr. W. R. Dakin, F.R.C.P., will be the speaker at St. George's. Mr. P. H. Pye-Smith, M.D., F.R.S., will preside at a house-dinner in the college dining-hall at Guy's, and the chair will be taken at similar functions in connection with the London Hospital by Mr. Lewis Mackenzie, F.R.C.S.; St. Mary's, by Dr. Farquharson, M.P.; Thomas's, by Dr. Cullingworth; Westminster, by Mr. Arthur Evans, M.R.C.S.; and King's College, by Dr. C. H. Allfrey.

Deaths under Chloroform.

An inquest was held at Newport (Mon.) last week on a boy, aged 13, who died under chloroform during the removal of adenoids. The usual verdict was returned, but we would call attention to the fact that the number of deaths under similar circumstances is unduly large and out of all proportion to the gravity of the condition. A man, aged 58, succumbed to chloroform narcosis at a University College Hospital on the 2nd instant. In the report before us it is stated that anaesthesia was commenced with the A.C.E. mixture, of which two ounces was used. Chloroform to the extent of six ounces was subsequently administered, and then the man died. In view of the fact that the operation only lasted three-quarters of an hour, this quantity appears strangely in excess of requirements, but possibly the reporter may unwittingly have exaggerated the amounts. The usual verdict was returned at the inquest.

Gallant Rescue.

Dr. NOEL HOOD, of York, was instrumental last week in saving the life of a small girl of six, who was in imminent danger of drowning, having fallen into the Ouse while playing on the banks with other children.

Substantial Donation to the Cancer Research Fund.

It is announced that Mr. William Waldorf Astor has presented to the Cancer Research Fund the magnificent sum of £20,000, which brings the total amount received up to £75,000. We are thus within measurable distance of the £100,000 endowment required for the systematic prosecution of the necessary researches.

Carriage Accident.

Dr. J. LIVINGSTONE, of Barty Dock, had a narrow escape last week from serious injury. While driving, his horse took fright at the sight of a traction engine, and bolted, the vehicle ultimately being thrown over. Dr. Livingstone was carried unconscious into a neighbouring house, but we are pleased to report that his injuries turned out to be comparatively slight, and he is now well on the way to recovery.

Fined for Non-Notification of Smallpox.

Mr. WILBURR RHYS, a Burton-on-Trent, practitioner, was fined £2 and costs last week for having failed to notify a case of smallpox to the twenty persons having contracted the disease in consequence of the delay in sequestration.

Smallpox at Cambridge.

The number of patients suffering from smallpox has now fallen to twenty-nine, so that the epidemic may be regarded as at an end.

Accidental Death.

Dr. C. M. MACAULAY, of Perth, met with his death last week under very tragic circumstances while on his holiday at Pitlochry, he having apparently fallen out of a window.
NOTICES TO CORRESPONDENTS, SHORT LETTERS, &c.

CORRESPONDENTS are requested to make use of a distinctive signature or initial, and to avoid the practice of signing themselves "Reader," "Subscriber," or "a Subscriber." Much confusion will be spared by attention to this rule.

ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

THE KILLED AND WOUNDED IN INDUSTRY.

In the interests of the legislation and inspection, industrial accidents do not, as a rule, decrease in numbers. Some years may be better than others, but any improvement is generally met in a year or two by a revival, to say nothing of new requirements causing an apparent increase. In some cases they may be the result of differences between solid and pneumatic tyres, and may add that as the sudden bursting of pneumatic tyres is frequently assigned as the cause of many casual and fatal accidents, the solids may be claimed to be safer as well as vastly more economical.

REMARKABLE FEMICIDE

A FEMICIDE has been recently presented to the Italian Government for a petition in favour of Signora Macri (Granata), who, during twenty years of married life, has become the mother of sixty-two children and has been cruelly and repeatedly murdered. Whether such an occurrence calls for reward and commendation is an open question. If it became general the Government would have to introduce a law for the protection of families, or an island might be assigned for the compulsory residence of irreproachable mothers.

DR. BEATTY—We regret we are unable to entertain your proposal.

THE TRAFFIC IN PROPRIETARY NOSTRUMS.

The sale of proprietary nostrums in the United Kingdom last year reached £2,700,000, no less than 40,078,556 packets having been stamped in accordance with the Act during that period. The total revenue from this source was £201,721, but it is noteworthy that of this sum only £122,926 came from Scotland. We may anticipate that the increase in view of the ever-increasing stringency with which the law is being enforced.

MRS. GREEN.—Thanks for offer, but the proposed contributions could possess but the remotest medical interest.

THE CASE OF DR. GRANT.

One interested—In reply to your inquiry we regret to have received nothing in favour of the已故的巴林巴尔医生. Upwards of £725 has now been raised in defence of the men's case in support of Dr. Grant, but the Court has decided that he must cease practice on the 10th which may be law, but does not accord with our ideas of justice. Everyone sympathises with Dr. Grant in the arbitrary conduct of the queer company of which he is the victim; the men still resolutely refuse to accept any other medical man, and thus the deadlock is accentuated.

MRS. H. B. AXEY.—The material sent is purely advertising, and can only be inserted in our columns as such.

APPOINTMENTS

ADKINS, G. C., L.R.C.P., M.R.C.S., Clinical Assistant in the Special Department for Diseases of the Throat at St. Thomas's Hospital.

CARMAN, N., L.R.C.P., M.R.C.S., House Surgeon to St. Thomas's Hospital.

DRAINAGE-HUNT, A. M., B.Ch.B, Glasgow, Resident Assistant to the North Staffordshire Infirmary, Lichfield, Staffs.

GUTHRIE, T. B., L.R.C.P., M.R.C.S., House-Surgeon to Out-patients at St. Thomas's Hospital.

HALL, A., B.B.Ch., L.R.C.P., M.R.C.S., House Surgeon to Out-patients at St. Thomas's Hospital.

HUMPHREY, A. G., M.B., B.Ch., Chief Assistant to the North Staffordshire Infirmary, Lichfield, Staffs.

JACKSON, E. H., M.A., M.R.C.S., Eton, House Physician to Patients at St. Thomas's Hospital.

PILKINGTON, G. B., M.A., B.Ch., Cantab., House Physician to Out-patients at St. Thomas's Hospital.

SHERMAN, C. N., L.R.C.P., M.R.C.S., Clinical Assistant in the Special Department for Diseases of the Skin at St. Thomas's Hospital.

URQUHART, R., L.R.C.P., M.R.C.S., House Surgeon to St. Thomas's Hospital.

VACANCIES

The Royal Infirmary, Sheffield.—Junior Assistant House Surgeon, Salary £200 per annum, 4 weeks' vacation, and washing. Applications to George Henry Day, Secretary.

Down District Lunatic Asylum, Downpatrick.—Junior Male Assistant Medical Officer. Salary £100 per annum, with furnished apartments, board, washing, fuel, light, and attendance. Applications to the Resident Medical Superintendent.

Metropolitan Hospital.—Casualty Officer and Pathologist and Registrar to the Hospital. Salary £100 per annum, Applications to Charles H. Byers, Secretary.

JERSEY General Dispensary and Infirmary.—Resident Medical Officer, Salary £150 per annum, with furnished quarters, coal, gas, and attendance. Applications to the Honorary Secretary, Jersey.

Kent County Asylum, Chatham, near Canterbury.—Third Assistant Medical Officer, Salary £140 per annum, 4 weeks' vacation, and washing. Apply to Medical Superintendent.

Brighton, Hove, and Saltdean.—House Surgeon. Salary £100 per annum with furnished rooms, coal, gas, washing and attendance. Applications to C. Somers Clarke, Hon. Secretary, 113, Queen's Road, Brighton.

Essex and Colchester General Hospital.—House Surgeon. Salary £100 per annum with board, washing, and attendance. Applications to the Honorary Secretary, Basildon.

Barnwood House Hospital for the Insane, Gloucester.—Junior Assistant Medical Officer, Salary £100 per annum for one year, and £110 per annum. Applications to R. J. Gill, Clerk of Union. (See advert.)

Ballyshannon Union.—Temporary Medical Officer. Remuneration three guineas per week. Immediate application to J. H. Ginn, Clerk of Union. (See advert.)

Beech—Medical Officer. Salary £150 per annum. Apply to Bessborough Spanking Co., Ltd. (See advert.)

BIRTHS

LEIGH.—On August 20th, at Park Road, Southend-on-Sea, the wife of B. Hilton Leigh L.R.C.P., M.R.C.S., and of a daughter. Applications to Honorary Secretary, Southend.

TILBURY FOX.—On September 2nd, at The Grays, Ashfield, Kent, the wife of Campbell Tilbury Fox, L.R.C.P., M.R.C.S., of a son.

MARRIAGES

GRANT.—Gilbert, of the City of London, to Margaret, daughter of Dr. D. Knechts- bull Road, S.E., Albert Green M.B., Lond., of Cheshelte, Derbys., To Gertrude Annesley, second daughter of William Gilbert, of Cornsor Road, S.R.

RANSON—Richardson.—On August 22nd at Hampstead church, of the late Mr. and Mrs. W. F. Richardson, of Cricklewood, of a son.

BRAY.—On September 2nd, at All Souls', St Margaret's-on-Thanet, Cuthbert, youngest surviving son of the late Rev. Vincent Raven, Rector of Great Fransham, Norfolk, to Mary Coombes, eldest daughter of the late John Burton, M.B., of Walsall, Staffordshire.

BREATHS

BAKER.—On September 1st, at 106, Upper Tooting Road, Mary Ann widow of John Wright Baker, surgeon, aged 77 years.

CADDIE.—On September 3rd, at 168, Brixton Road, S.W., Martha Margarett, the beloved wife of W. Townley Caddie, M.B., and daughter of the late Fleet-Surgeon S.D. Graham, board and residence.

INTRODUCTORY REMARKS.

In April, the poet tells us, the young man “lightly turns to thoughts of love,” but in accordance with a time-honoured custom, at the beginning of October, what time the Virginia creeper has donned, nay, almost lost, its bright autumnal tints, the young man who is fired by a desire, or has been coaxed into willingness, to pursue the study of medicine as a means to an end is fain to betake him to the precincts of a medical school, where, with or without some introductory remarks by one of the junior members of the staff, he will have to commence forthwith the career which may lead him to fame, possibly even to riches, but, failing these, will, with average application and good conduct, provide him with the means of livelihood, and, in the fullness of time, enable him to marry and rear a family, should this be one of his day-dreams. If we greet with a sceptical smile the optimist who decks the practice of medicine in rainbow colours and uses up his superlatives in emphasising its beneficial and honourable aspects, we view with distrust bordering on abhorrence the intellectual neurotism who elects to dwell upon its shortcomings, its difficulties, and the, in general, unsatisfactory returns which it yields to its adepts. In verity the one and the other are equidistant from the sober truth. The practice of medicine is a calling like any other, in that, to attain success, its follower will have to put in plenty of hard work, he will have to submit to the inevitable disservices which he may not, after all, attain the dignity of a title or become a territorial magnate. It has, however, its peculiar advantages in that the man who conscientiously recognises and fulfils his responsibilities, who is kind to the weak and sympathetic to the suffering, who conscientiously does his level best, regrettting that it be not in his power to do more and better, he, at any rate, is tolerably certain to rejoice in the esteem and consideration of his fellow-citizens, and to live a life, if not of luxury, at any rate of comfort. The key to the situation is admirably given in the aphorism that “medicine is a wholly admirable profession, but for the most part it is not a good business.”

It would be well, both for the profession and for the individual, if only those took up the practice of medicine who, in virtue of a particular temperament, experience an anticipated pleasure in ministering to the wants of the sick, or who evince special aptitudes for the study of some of the many unsolved problems which await solution. The medical profession may be roughly grouped in two categories—those who give themselves up to what we may call curative medicine, and a more limited class who seek to derive, from close observation of the sick, the means of advancing our knowledge.

There is in the study and practice of medicine ample scope for talents of the most varied kind. If, unfortunately, a tendency manifests itself in the daily practice of the healing art to fall into a routine, to treat disease by rule of thumb, that is the fault, or the defect, of the individual practitioner. The calling is one in which the individual practitioner is called upon to exercise independence of judgment, seeking in his own sphere to winnow the wheat from the chaff in the huge collection of principles, dogmas and views bequeathed to us by our predecessors in the profession. We would impress upon every intending student that it lies with him to utilise the experience which will be his to assist in throwing light into dark corners—not so much by the publication of an occasional case of exceptional interest, but by endeavouring to deduce some general law, some vital principle, from the morbid phenomena which come under his notice. He should never forget that he is always a student—no longer a listener at compulsory lectures but perform an observer, more or less thorough, more or less conscientious, of the working of Nature’s laws, some of which we see as through a glass darkly, others, the majority, of which we know little or nothing. Some epoch-marking discoveries have come from the hands of the general practitioner, and assuredly it is never the material that is wanting.

THE CHOICE OF A SCHOOL.

Apart from the fact that the choice of a school has presumably already been decided by our student readers, the selection is usually determined on other than purely theoretical considerations. Hereditary antecedents and geographical reasons enter for a large part into the question. The matter of fees, again, is not absolutely foreign to the decision, though in view of the trifling differences this ought not to be allowed great weight. Speaking generally, the student possessed of special aptitudes, especially he who has fashioned his mind by an arts course at one or other University, will stand a better chance at one of the larger Metropolitan schools, where the prizes are more valuable and where he is brought into contact with the most eminent and best known teachers. More particularly is this the case when he aims at the higher qualifications as a passport to hospital appointments and consulting practice.

THE CHOICE OF QUALIFICATIONS.

No sooner has the study of medicine been entered upon than the student is called upon to define his aims, in other words, he has to decide through what portal he will enter the profession. The point is one of unquestionable importance, because there is no going back on the choice later on in the student career. The
reorganisation of the University of London has rendered it possible for the average student to obtain a degree in medicine on terms less prohibitive than was formerly the case, but the fact remains that although the purely medical standard is attainable by any fairly diligent student, the clinical examination and that in science constitute very serious stumbling-blocks. The average student will probably find it more convenient to take the diplomas of the English Joint Board, and, should he deem a degree worth the extra trouble, he can put in attendance at one or other of the provincial Universities with the view of subsequently passing the examinations for the doctorate.

THE COURSE OF STUDY.

It is unnecessary to discuss the details of the medical curriculum. We would, however, impress upon the student the importance of entering upon his work earnestly, with firm determination to familiarise himself with the subjects—anatomy, physiology, and materia medica—which constitute the threefold basis of practical medicine. And in respect of anatomy, the only valuable knowledge is that gained by actual dissection of the dead body. Verbal descriptions and plates are only aids to knowledge, not knowledge itself. Dissection gives information at first hand—actual knowledge, not mere statements—and the very practice of dissection is a first course in surgery. We would warn the student against that form of intellectual laziness which consists in abandoning the dissecting-room in favour of the library. The latter course may enable the student to pass examinations, but it will never confer that intimate familiarity with the human frame which is indispensable to success in practice. Nor should he despise the study of that somewhat arid subject, materia medica. A knowledge of the physical properties of drugs and of their physiological action is as important to the hospital physician as to the general practitioner. Treatment is the ultimate object of medicine, and the medicinal treatment of disease is still an integral part of the practice of medicine.

THE CLINICAL WORK.

It is in the wards and in the out-patient department, after all, that the student acquires most of his information concerning the course and treatment of disease. There he watches the daily progress of morbid processes, and learns the means employed to afford relief or to bring about recovery. It will be his privilege to unravel the tangled threads of each patient’s life-history, and by the careful collection and careful examination of data to arrive at a reasoned conclusion known as the diagnosis. In this way he will gradually learn to recognise the main principles which underlie the practice of medicine. Each patient who comes under his observation will, if properly studied, yield his quota of practical knowledge, and the value of the opportunity depends upon the ability and willingness of the student to avail himself thereof. The object and aim of clinical training is to cultivate the student’s powers of direct observation and to train him to make correct deductions, and the habit of careful observation is one which should become second nature. The instruction received in the wards is incomplete unless supplemented by the lecture and demonstration in the post-mortem room. The post-mortem examination is the touchstone of diagnosis, and, in some cases, the opprobrium of treatment. There the student can follow the morbid process to its logical conclusion. The post-mortem room is the natural complement of the ward, and it is often only in this room that the clinical problem is unravelled and the student enabled to observe the organic lesions which determined the symptoms he has been studying. Incidentally the student should learn as much as he can of the method of carrying out these examinations, for it falls to the lot of most practitioners to have to make such examinations, and errors of observation or appreciation may be fraught with the gravest consequences to possibly innocent persons.

THE HIGHER QUALIFICATIONS.

There remains the question of the higher qualifications, e.g., the Fellowships of the Royal Colleges, which are indispensable to those who contemplate a hospital career, either as physician or surgeon. The Fellowship of the Royal College of Physicians is not obtained by examination, but by selection from among the members. Candidates for the membership are required to pass a searching examination and to satisfy certain other requirements before they can be admitted thereto, and subsequent elevation to the Fellowship is largely a matter of personal influence, though merita per se is not a bar to selection. The Fellowship of the Royal College of Surgeons, on the other hand, is a purely professional distinction, and is open to anyone who can pass the examinations. It is advisable to pass the first examination for the Fellowship as soon as possible after passing the first membership, in order not to have to go over the ground afresh later on.

CHOICE OF A CAREER.

For five long years at a minimum the student’s ambitions do not soar beyond the boards of examiners. To obtain the right to practise is, for the time being, the object of his existence. When he has entered the portals of the profession he is confronted with a troublesome question of deciding in what particular path he shall direct his energies. Many neo-practitioners, not unwisely, spend a year or two in resident appointments at their own hospitals or at some provincial hospital, infirmary, &c. Others acquire a knowledge of the practice, as distinguished from the theory, of medicine by serving as assistant or locum tenens. Others, again, either join their parents in practice or purchase partnerships. Then, too, there are the Services—Indian, Army, Navy, and Colonial—to choose from. The Poor-law Infirmaries provide each year a certain number of appointments, and these are the first rungs of the ladder which leads to the superintendency of these institutions. These posts are fairly remunerated, and afford reasonable security of tenure, but they entail much hard work, together with heavy responsibilities.

PUBLIC HEALTH SERVICE.

Every student who can afford the time is strongly advised to qualify in State Medicine, since this diploma renders its holder eligible for appointment as medical officer of health, and, moreover, the knowledge thus gained is invaluable in every department of practice. A diploma in State Medicine entails a special course of preparation and training subsequent to qualification, the conditions of which will be found under the appropriate heading. Although the tenure of office is not as yet on a satisfactory basis, there are many valuable appointments of the kind which afford magnificent scope for intelligent activity.

POST-GRADUATE INSTRUCTION.

Medicine, with its continually widening scope and added requirements, has become a field of vastly greater extent than was the case a few decades ago, and when he enters upon his professional work the conscientious practitioner is apt to experience a painful sense of his.
shortcomings in very many branches of medical practice. The knowledge which has been rendered available in recent years has obviously placed a peculiar responsibility upon the physician fresh from his studies. The desire so generally felt by men in practice to extend and complete their knowledge of special subjects has led to the organisation of post-graduate institutions on a large scale, of which advantage is freely taken by those who are fortunate enough to reside within accessible distance thereof. We would strongly urge senior students and young practitioners to avail themselves of every opportunity to acquire a working knowledge of the various special branches—eye, ear, throat, gynaecology, &c. This leads us to the question of

**SPECIALISM IN MEDICINE.**

Hitherto the student has been taught that "the greatest mistake of all is to start in a specialty without being thoroughly grounded in general practice." Admitting that it behoves everyone, no matter what particular department of practice he may decide to adopt, to have acquired a thorough grounding in the general body of medicine, it is impracticable for him to devote much time to a general practice. On the contrary, there is much to be said in favour of the view that it is best for the young practitioner to make his choice at the earliest possible moment of the line of work which he designs to follow. Vacillation at this early stage of his career does not tend to beget confidence among his elder colleagues, and certainly does not improve his chances of making a reputation as a specialist. As soon as he has qualified, therefore, or as soon after as may be, the intending specialist should endeavour to obtain a junior post in one or other of the special hospitals, where he can gradually work his way up.

**MEDICAL PRACTICE IN FOREIGN COUNTRIES.**

Practitioners qualified in Great Britain who desire to practise their profession abroad are still confronted with many difficulties. True, a step in the direction of reciprocity has been taken in the case of Italy, but elsewhere in Europe considerable difficulty will be experienced in obtaining permission to practise; indeed, with the one exception of Italy, it is usually necessary to go through the whole curriculum and pass the examinations in their entirety.

**LONDON SCHOOLS.**

The Schools of Medicine in the Metropolis are the following. Scholarships, prizes, students' appointments, fees, &c., being set forth in connection with each place named. The names of the hospital staff, lectures, residential terms, and detailed information will be found, as a rule, in our advertisement column.

**St. Bartholomew's Hospital.**—This hospital has 750 beds, and for many years past the school attached has had a larger number of entries than any other medical school in London. Collegiate residence is here permissible, subject to the ordinary rules. The recreation ground for the use of students is at Winchmore Hill.

**Appointments.**—Ten house physicians and ten house surgeons are appointed annually. During the first six months of the year they act as "junior" house physicians and house surgeons, and receive a salary of £25 a year. During their second six months they become "senior" house physicians and house surgeons, and are provided with rooms by the hospital physicians and surgeons, and receive a salary of £30 a year. A resident midwifery assistant and an ophthalmic house surgeon are appointed every six months, and are provided with rooms and receive a salary of £30 a year. Two assistant anaesthetists are appointed annually, and receive salaries of £120 and £100 a year respectively. An extern midwifery assistant is appointed every three months, and receives a salary of £50 a year. Chief assistants and clinical assistants are appointed in each of the special departments. In-patient dressers, in-patient clinical clerks, clerks, and dressers to the assistant physicians in charge of the physicians and surgeons in charge of special departments are appointed every three months without fee.

**Scholarships, &c.**—There are four open scholarships in science, £75, £50, £50, £50, tenable for one year, and a Jeffreson exhibition, value £50; at the end of the first year four junior scholarships of £50, respectively; Treasurers' prize for practical anatomy; Foster prize in practical anatomy; senior scholarships, value £50, for anatomy, physiology, and chemistry; Wrix prize, Hichens prize, Lawrence scholarship and gold medal, value 40 guineas, for medicine, surgery, and midwifery; two Blackenbury scholarships, of £39, in medicine and surgery; Bentley prize, for reports of surgical cases; the Kirkes gold medal for clinical medicine, with scholarship of £50. Shuter scholarship of £50; Skynner prize of £50; Sir G. Burrows' prize of £10, and Matthews Duncan medal and prize, value about £20; the Treasurer's Research Studentship, of the usual value, the Sir Francis Galton medal and prize, being required to engage in research original in pathology.

**Fees.**—By payment of a composition fee, a student is entitled to attend all the courses of instruction, and to hold the various clinical appointments. For students commencing their medical studies:—Entrance fee, 30 guineas; annual fee, 30 guineas, for five years. A student on qualification at the end of the five years is not liable for any further fees, and receives a perpetual ticket. Should he fail to qualify in this time, the fee for further instruction is 10 guineas for each six months. Fees for University students:—Entrance fee, 20 guineas; 30 guineas annually for two years, and 10 guineas for each six months if not qualified. Fees for preliminary scientific students:—20 guineas; for laboratory instruction for D.P.H., 15 guineas.

The Warden, Mr. W. D. Harper, will furnish further details on application.

**CHARING CROSS HOSPITAL.**—The school attached to this hospital is situated in central London, and contains new physiological, pathological, and bacteriological laboratories, materia medica and anatomical museums, an anatomical theatre, enlarged dissecting-room, and a chemical theatre. The hospital and convalescent home contain 260 beds available for clinical study.

Clinical instruction is given in medicine, surgery, and obstetrics, and in the special departments of dermatology, the skin, diseases of children, mental disorders, the throat, the eye, nose and ear, and in the orthopaedic, Röntgen, and electrical departments.

**Scholarships, Medals, &c.**—The Livingstone scholarship (100 guineas), the Huxley scholarship (35 guineas), and six other entrance scholarships, total value £500, are awarded annually. Two scholarships of the value of 72 guineas each are reserved for students of Oxford, Cambridge, or London Universities. All are awarded annually. Two Universities scholarships, value 72 guineas each, are open to students from the University of Oxford who have passed the 1st M.B., to students of the University of Cambridge who have passed the 2nd M.B., and to students of the University of London who have passed the intermediate examination in medicine. Candidates must give notice to the librarian of their intention to compete on or before September 21st, 1903. The Golding prize of £10 is open to students at the end of their first winter session. The Huxley medal, with a prize of £10, is open to students at the end of their second winter session. The Pereira prize of £5 is open to all general students. The Llewellyn prize of £25 is awarded annually. The Governors' Clinical Gold Medal is also open to students at the end of their curriculum, and a silver medal or its equivalent in books is awarded to the most distinguished student in each class.

**Appointments.**—The curator and pathologist is ap-

Pointed annually, and receives £100 a year; medical and surgical registrars to the hospital receive £40 a year each. A place in the special department in the hospital is given to six house physicians, six house surgeons, and two resident obstetrical officers are appointed each year; clinical clerks and dressers are appointed in all the general surgical and medical wards. At the hospital is a large residential college with rooms for about sixty men, whilst for students who prefer to live in the suburbs, no other hospital is so conveniently placed, the Daily News accommodation being good and close at hand. There is now a complete School of Dental Surgery at this Institution, which is recognised by the Royal College of Surgeons of England; the facilities for dental study within the walls of one hospital will be appreciated by those intending to practise dentistry.

Appointments.—Eight house surgeons, eight house physicians, eight assistant house surgeons, eight resident obstetrical officers, four assistant house surgeons, eight ophthalmic house surgeons, twenty-four ophthalmic assistants, and ninety-six dressers are selected annually from the students according to merit, and without payment. There are also a large number of junior appointments, every part of the hospital practice being systematically employed for instruction.

Scholarships.—Open scholarships of £100 and £50 in classics, mathematics, and modern languages. Open scholarships of £300 and £50 in chemistry, physics, anatomy, and an open scholarship of £50 for University students in two of the following subjects: Anatomy, physiology, organic chemistry, zoology, physics. The following are the scholarships, prizes, and exhibitions open to students of the hospital:—The Arthur Durham prizes for dissection, £15 and £5; Junior prizes for general proficiency, £50, £30, £50; Hilton prize for dissection, £5; Michael Harris prize for anatomy, £10. Sands Cox Scholarship for physiology, £15; Woolridge prize for physiology, £10; Beeley prize in pathology, £34; Golding-Bird prize in bacteriology, gold medal, and £30; Treasurer's gold medal in clinical medicine; Treasurer's gold medal in clinical surgery; Beeley studentship in materia medica (tenable for 3 years), annually £31 10s.; Gull studentship in pathology (tenable for 5 or 3 years), annually £50. The Physical Society awards two prizes, each of £5, to the authors of the best essays on selected subjects, prizes of £50 and £5 for the best papers read before the Society and a prize of £5 to the member who has most distinguished himself in the debates of the session.

New School Buildings.—A considerable addition to the school buildings was made in 1897, comprising a series of class-rooms, laboratories, and a lecture theatre for the teaching of physiology. During the past year the magnificent Wills Library has been completed.

Fees.—A new system for payment of composition fees has been instituted at this school during the past year. Particulars may be obtained on application to the Dean, Guy's Hospital, S.E. 9, King's College Hospital.—This hospital is centrally situated, being contiguous to the Royal College of Surgeons, Lincoln's Inn Fields. The College adjoins Somerset House and is close to the hospital, in which there are 220 beds available for clinical teaching, of which, ear, throat, skin, and dental departments are attached to the hospital. Some wards are specially devoted to children's diseases. The wards have been recently refloored and the electric light installed throughout.

Scholarships.—£800 are awarded annually in scholarships and prizes. At entrance, a science exhibition of £100 value is open to all candidates under the age of nineteen; two scholarships of £20 each for candidates (two subjects literary) are open to students commencing their curriculum. A scholarship, value £50, is open to students of a British University who come up to London to complete their curriculum; two junior scholarships of £50 each for third year students, of £50 for third year students in residence, and one of £40 for fourth year students. In addition, students may compete for the Daniel scholarship, value £40; the Wills scholarship, value £50; the Ethelbert scholarship, value £20; the Carter, Todd, Jelf, Tanner, Leathers prizes, and all class and clinical prizes.
Students' Club, which, with the reading and smoking rooms, now form part of the college buildings. The "London Hospitals' Club Union" has a field for cricket, football, &c., with an excellent pavilion, at Hale End. The clubs and societies are open to all the students, and are warmly encouraged by the staff. The club rooms, gardens, and fives court are now open. Full particulars of the Warden, Mr. Munro Scott.

St. Mary's Hospital. — This hospital is situated at Sidcup, near the terminus of the Great Western Railway, and at present contains 281 beds. Fresh laboratories, fitted with electric light and all modern improvements, for the study of pathology and bacteriology, have recently been added, and also a new physiological lecture room. A special department of pathological chemistry has been instituted. The new wing, the ground-floor of which, comprising the new out-patient department, was opened in 1898, will be completed in 1904. This will add to the hospital eighty-one new beds, and will include additional operating theatres, a new clinical laboratory, a clinical theatre, and an X-ray department.

Appointments. — All clinical appointments in the hospital are free to students of the Medical School, and the resident medical officers are chosen by competitive examination. Six house physicians, six house surgeons, four obstetric officers, and two resident assistant officers are appointed each year, and receive board and residence in the Hospital.

Scholarships, &c. — One scholarship in anatomy and physiology in the University of £145, open to any gentleman who has not completed a winter session of the medical school. Two scholarships in natural science, each of the value of £78 15s., and one of £52 10s., under the same conditions. Two scholarships, each of 60 guineas, open to students from the Universities of Oxford and Cambridge. The scholarships will be awarded by examination on September 22nd and 23rd.

Fees. — Fee for attendance on the full five years' course in hospital practice and all anatomical instructions, and special tutorial classes, £140, paid in one sum on entering the school; or in instalments, £145.

Students who have completed their examinations in anatomy and physiology at the Universities of Oxford, Cambridge, or other University, are admitted as perpetual pupils on payment of a fee of 60 guineas in one sum, or 65 guineas in two annual instalments. University students, prior to completing the anatomy and physiology examinations, are entitled to 25 guineas. After completing the anatomy and physiology examinations, the inclusive fee may be paid.

Research students, who are provided with free board and rooms, are held throughout the year.

Middlesbrough Hospital. — This hospital, which is conveniently situated in the centre both of business and residential London, contains 346 beds. There are special departments for cancer, and for ophthalmic, throat, aural, skin, dental, and children's diseases. Wards are also devoted to cases of uterine disease. The new school buildings are now in regular use. Residence for students is obtainable in the residential college, which has its frontage on the hospital garden.

Appointments. — Casualty surgical officer, casualty medical officer, six house surgeons, six house physicians, and two resident obstetric physicians. The above officers have residence and board in the college free of expense. Clinical clerks and dressers in all the departments are also appointed in addition to the foregoing. Scholarships, &c. — Three entrance scholarships of the value of £100 and £50 respectively. One entrance scholarship of the value of £50, open to Oxford and Cambridge students only. (Subjects—Anatomy and physiology, including histology.) Three scholarships of 60 guineas and £40 respectively, for medical science and surgery: John Murray medal and scholarship, awarded every third year; the Governor's prize of £21 for students in their final year. Hetley clinical prize, £25, awarded annually for the best paper on the subject of clinical medicine, surgery, and obstetrics; the Lyell Gold Medal in surgery, and surgical anatomy; the
Leopold Hudson prize, value £11 guineas, in surgical pathology, including bacteriology; Freeman scholarship, £30, in obstetrics and gynaecology; exhibitions of 10 guineas and 5 guineas for anatomy and physiology to second and first year's students respectively, as well as class prizes in all subjects.

Fees.—General fee for the entire course of hospital practice and lectures, 135 guineas, if paid in one sum on entrance, or by instalments of 60, 50, and 35 guineas, payable at the commencement of the first, second, and third years. General fee for members of the University who have completed one year of medical study, 90 guineas, if paid in one sum, or by instalments of 60 and 40 guineas. For those who have completed their physiological and pathological studies the fee is 25 guineas on entrance, or in two instalments of 40 and 35 guineas. The composition fee for London University students who have passed the preliminary science examination is 120 guineas. The fee for the curriculum for dental students is 54 guineas on entrance, or two instalments of 40 guineas and 20 guineas.

St. Thomas's Hospital.—This hospital, with medical school attached, is situated on the southern outskirts of the House, on the west of the House, and comprises the House, Museum, and Library. It is well adapted for the modern teaching of large bodies of students in all subjects of the medical curriculum. There is a large library and museum, and a great museum and library.

A clinical laboratory is provided, in which all the more difficult methods of diagnosis, bacteriological, chemical, and microscopic, are carried on under the direction of a superintendent. The department for out-patients has been re-arranged so that large numbers of students are enabled to follow closely the practice and teaching of the assistant staff. This department has been added a completely fitted operating room.

Appointments are open to all students. A resident assistant physician and a resident assistant surgeon are appointed annually at a salary of £500 with board and lodging; a resident casualty officer at a salary of £50 per annum. Two hospital registrars, at an annual salary of £400 each, are appointed yearly. The tenure of these offices may be renewed for a term not exceeding two years. An obstetric tutor and registrar is appointed at an annual salary of £350. A house physican, two house physicians to out-patients, four house surgeons, four house surgeons to out-patients, two obstetric house physicians, two ophthalmic house surgeons, and eight clinical assistants in the special departments are appointed every three months. Scholarships, Prizes, &c.—Three entrance scholarships are offered for competition in September, viz., one of £150 and one of £50 in chemistry and physics, with either physiology, botany, or zoology at the option of the candidate; for first year's students, one of £50 open to University students who have passed in anatomy, physiology, materia medica, and pharmacy for a medical degree in any of the Universities of the United Kingdom, and have not entered as students to the London medical school. Copies of the examination papers of last year may be obtained on application to the medical secretary. Applications must be sent in not later than September 15th, with certificate of birth and of preliminary examination, and with a notification as to the optional subject chosen. Numerous scholarships, prizes, and medals are open to competition throughout the whole career of a student, including a Fellowship of £100 given by the Salters' Company for research in pharmacology.

Special courses of instruction for the Preliminary Scientific and Intermediate, M.B.Lond., for the Oxford and Cambridge examinations, and for the Prima're and Final F.R.C.S. are held throughout the year.

A register of approved lodgings is kept by the medical secretary, who has a list of local medical practitioners and others who receive students into their houses. The prospectus of the school, containing full particulars as to fees, course of study advised, &c., and all necessary information, may be obtained on application to Mr. Rendle, the medical secretary.

University College Hospital is situated in Gower Street, not far from Euston Railway terminus. The college where the classes are held faces the hospital, on the opposite side of the street. The number of beds available for teaching purposes is 188, all the hospital is under control of the University.

Appointments.—Eight house physicians, six house surgeons, four senior and four junior obstetric assistants, and two ophthalmic assistants are selected annually by examination from among the senior students, without competitive examinations. The house physicians and surgeons in the hospital for a period of six months, and the senior obstetric assistants for three months, and receive their board and lodging free. The offices of out-patient physicians' and surgeons' assistants, clinical clerks, surgeons' dressers, and ophthalmic surgeons' assistants are filled by pupils who are also students of the college, without additional fee.

Scholarships, &c.—Entrance scholarships: One of the value of £120, and two of 60 guineas for proficiency in science, the subjects being those of the Preliminary Scientific Examination of the University of London, and two of 80 guineas each, the subjects being anatomy and physiology: the Atkins scholarship of £45 a year, tenable for three years; the Atkinson scholarship, value £55, tenable for two years; the Sharpey physiological scholarship, value £105 a year, tenable for three years; the Sharp physiological scholarship, in pathological anatomy, value £30; the Erichsen prize, operating case, value £10 10s., awarded for practical surgery; Dr. Fellow's clinical medals, the Liston gold medal, Alexander Bruce gold medal, Cluff memorial prize, Tuke medals for pathology, class medals, &c., gold and silver medals or other prizes, as well as certificates of honour, are awarded after competitive examinations in particular branches of study; the Tuffnell scholarship of £40 for two years; and the Clothworkers' exhibitions in chemistry and physics of £30 each, can also be held in the medical faculty.

For the following have been grouped to meet the requirements of the various examining boards: 1. For the medical examination required by the Examining Board in England and the Society of Apothecaries: 100 guineas, if paid in one sum at the examination of the course: 155 guineas if paid by instalments. 2. For those students who do not require to attend chemistry, pharmacy, and elementary biology at a medical school (under the regulations of the Examining Board in England) the fee is: 135 guineas if paid in one sum; 140 guineas if paid by instalments. 3. For the courses necessary for the Preliminary Scientific Examinations of the University of London, 25 guineas. 4. For the course of instruction for the Intermediate Examination in Medicine of the University of London, 60 guineas if paid in one sum; 62 guineas if paid by instalments. 5. For the course of instruction for the final M.B. examination of the University of London, 80 guineas if paid in one sum; 82 guineas if paid by instalments. This course of instruction is also suitable for the corresponding examinations at the Universities of Oxford, Cambridge, and Durham. 6. Composition fees for dental students, for the course required for the L.D.A. examination, 65 guineas, or exclusive of chemistry, practical chemistry, physics, and materia medica, 50 guineas. The composition fees 1, 2, 4, and 5 admit to attendance on systematic lectures and to hospital practice, where this is included in the fee, during five years.

Westminster Hospital.—This hospital is conveniently situated, facing the Abbey, and is readily accessible from all parts of the metropolis, having 205 beds for general cases, and all the special departments. New school buildings have been erected close by which afford accommodation for 150 students. The class rooms, dissecting rooms, and lecture theatre are in excellent condition; the hospital is well equipped for research and study.

Appointments.—Medical and surgical registrars, each £40 per annum; two house physicians, two house sur-
• geons, two assistant house surgeons, and resident obstetric assistant. These officers, except the two first named, are all boarded free of expense. Fourth-year students are appointed to be clinical assistants in the various departments.

Scholarships, &c.—(a) Winter Session—The Guthrie scholarship £60, entrance scholarship £40, entrance scholarship £30, dental scholarship £20; subjects, Latin, mathematics, experimental physics, chemistry, and, at discretion, French. Free presentation, open to pupils of Epsom Medical College. (b) Summer Session.—Natural science scholarship, £60, same as for Pres. Sci. of University of London. Natural science scholarship, £40, chemical laboratory, £30, subjects anatomy and physiology. Natural science scholarship, £60, same as for Pres. Sci. of University of London. Free presentation, open to pupils of Epsom Medical College. (c) Prizes.—Treasurers', 10 guineas, for first-year's men; Chadwick, 20 guineas for students of any year not exceeding fifth. To be awarded for unqualified men. Bird medal and prize, £14, for students who have completed the fourth winter session. Sturge prize in clinical medicine, £8, clinical surgery prize, £5, to be competed for by unqualified men. Any prizes open in the various subjects.

Fees.—In one payment of 110 guineas, or two payments of 60 guineas each, payable on entrance and at the commencement of the second year respectively, or by six instalments at the end of six sessions of 25 guineas each and 20 guineas alternately. Fees for shorter periods or for single courses may be learned on application to the Dean. Fees for dental students, payable in one sum on entrance, 50 guineas, or in two instalments of £35 each.

LONDON SCHOOL OF MEDICINE FOR WOMEN (ROYAL FREE HOSPITAL).—This school, which is situated in Hunter Street, Brunswick Square, opens at the same time as, and the periods of study, lectures, &c., are similar to those at the other medical schools. A dissection-room, physiological, chemical, biological, physical, and pharmaceutical laboratories and library are provided at the school, and clinical lectures are regularly delivered at the Royal Free Hospital close by, which institution is appropriated to the students at the School as a field of practical study; all clerkships and dresserships are open to the students of the School. Resident and post-graduate posts are open to the students on the same conditions as at the other medical schools. Numerous scholarships and prizes are awarded, particulars of which can be obtained on application.

Fees.—The fee for the Intermediate and Final M.B. course is £50 if paid in one sum, or £55 if paid in three instalments. The fee for the Course for the Conjoint Colleges of Scotland, &c., including Elementary Science, is £100 if paid in one sum, or £105 if paid in three instalments. The fee for hospital practice and clinical teaching is £35, or £40 paid if paid in instalments.

Special classes for the Preliminary Scientific examination of the University of London. For the whole course, £30.

EXTRA-ACADEMIC INSTITUTIONS IN LONDON.

LONDON SCHOOL OF DENTAL SURGERY.—This institution is the oldest of the Dental Colleges in the United Kingdom, and its teaching is recognised by the Royal College of Surgeons for the dental diploma. It is centrally situated in Leicester Square, is open daily, and under the supervision of a special staff and house surgeons. The mechanical laboratory is the most perfect of its kind, and its usefulness can hardly be overstated. The Hospital having been recently enlarged, the accommodation is equal to all requirements. Demonstrators have been appointed to instruct the new students in the elements of operative dental surgery, and at the beginning of the session each department gives a course of classes on this subject. There is the Saunders scholarship and Entrance scholarship, value £20 each, and other prizes awarded yearly, the Storer Bennett Research scholarship, value £50, awarded triennially, and the eight house-surgeons are filled by students of the hospital holding the L.D.S. Fee for two years' hospital practice required in the curriculum, including lectures, £30 for three years' tuition in dental surgery is 150 guineas.

NATIONAL DENTAL HOSPITAL.—This institution is situated near the border of North-West London (Great Portland Street, W.), and the same teaching facilities and hospital practice are obtainable here as at the foregoing institution, special demonstrations being given by members of the staff. There are also a mechanical laboratory, bacteriological, chemistry and botany, and students' common room, a metallurgical laboratory, extraction and storage rooms, lecture hall, regulations room, &c., all lighted by electricity, and warmed and ventilated after the most approved requirements; in fact, this institution may be pronounced a model dental hospital and school. The winter session commences at the same time as at the medical schools, on October 1st. The medical tutors hold special classes before each college examination. The prizes include two entrance exhibitions, value £40 and £30, and the Rymer prize of £35. The fee for two years' hospital practice required by the curriculum, including lectures, is £40.

LONDON SCHOOL OF TROPICAL MEDICINE.—This Institution is the outcome of a suggestion by the Right Hon. Joseph Chamberlain, H.M. Secretary of State for the Colonies, and is situated at the Royal Victoria Docks, in connection with the Seaman's Hospital, to which no medical school is attached, where the school has arrived there in great numbers from the Tropics, affording immediate opportunity for the study of tropical diseases. The school buildings are placed within the hospital grounds, and systematic courses of instruction are obtainable from duly authorised teachers throughout the year. Students also have the privilege of attending the medical and surgical wards of the Seaman's Hospital, Greenwich. Information as to fees, &c., can be obtained of the Dean or the Secretary.

Medical students are admitted to a practice of the following Metropolitan hospitals, to which no medical school is attached. Detailed particulars will be supplied on application to the various secretaries.

WEST LONDON HOSPITAL, Hammersmith.—This contains over 150 beds, and has an extensive out-patient department. Dresserships and clinical clerkships may be obtained. Two house surgeons and two house physicians are selected every six months. Special departments have recently been opened for diseases of the throat, ear, skin, and deformities. An electric department has also been added. The practice of this hospital is reserved exclusively for medical men, junior students not being admitted.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway Road, N.—This institution has been recently enlarged, contains 159 beds, and is now recognised for study during the fifth year by the Conjoint Board. The practice of the hospital is open to practical, and medical and pathological assistants are appointed in the wards and out-patient departments, as in the larger general hospitals.

BETHLEHEM ROYAL HOSPITAL.—Two resident house physicians who have recently obtained their diplomas to practise medicine and surgery are elected every six months, and are provided with apartments, complete board, attendance, washing, and an honorarium of 85 guineas per quarter. The students of a certain specified London medical schools receive clinical instruction in the wards of the hospital, and qualified practitioners may attend for a period of three months on payment of a fee. Post-graduate lectures are also given in these hospitals.

NATIONAL HOSPITAL FOR EPILEPSY AND OTHER DISEASES OF THE NERVOUS SYSTEM, Queen's Square,
W.C.—Contains 200 beds. It has on its staff men of European reputation, and the institution is recognised by the Board whereof the fifth of the fifth of study may be devoted to clinical work. Clinical clerks are appointed to the physicians for out-patients, and courses of lectures and clinical demonstrations are given each year.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—The largest institution for the treatment of affections of the chest in the United Kingdom, there being 320 beds in the two buildings. There are also 50 beds for patients who reside in the hospital, each for a period of six months. Lectures and demonstrations are given by members of the medical staff on Wednesdays and Fridays at four o'clock, save during vacations. Terms:—£5 5s. perpetual. This hospital is recognised by the Conjoint Board, the University of London, and the Apothecaries' Society.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park.—This is a large and well-equipped hospital at the East End, containing 164 beds. Clinical lectures and demonstrations are given by the members of an exceptionally experienced staff. Fee for three months' attendance on hospital practice, 2 guineas; six months, 3 guineas.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road.—(80 beds.)—This hospital has been enlarged by the provision of complete out-patients' department, and also by the erection of a new wing, which provides accommodation for 80 in-patients.

THROAT AND EAR HOSPITALS.

CENTRAL THROAT AND EAR HOSPITAL, Gray's Inn Road, contains seventeen beds, with an extensive out-patient department recently enlarged. Clinical demonstrations and instruction to qualified practitioners and senior students daily during the hours of the hospital's visits. Twelve clinical assistants who must be duly qualified, are elected to assist the surgeons. Operation days—In-patients, Tuesdays, 2:15 p.m.; out-patients, Tuesdays and Fridays, 2 p.m. Fees for the three months' attendance, £3 3s.; six months', £5 5s. Full details of this institution and post-graduate work will be found on reference to our advertising columns or on application to the Dean.

HOSPITAL FOR DISEASES OF THE THROAT, Golden Square, W., contains 50 beds. Students are admitted to hospital practice on payment of fee for three months' course, £5 5s.; for six months, £7 7s.; perpetual, £10 10s.

WOMEN AND CHILDREN.

THE HOSPITAL FOR WOMEN, Soho Square.—The hospital contains 61 beds. In connection with this institution there is now an organised school of gynaecological medical men and to students for their third year. Clinical assistants to the physicians and surgeons in the in-patient and out-patient departments are appointed every three months. Fee for the three months' course, and certificate, £6 8s.

THE SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN, Lower Seymour Street, W., offers excellent opportunities for clinical study and training in the details of operative gynaecology. The success of the staff in this department have gained for them a European reputation. There are 47 beds.

HOSPITAL FOR SICK CHILDREN in Great Ormond Street, Bloomsbury, W.C., and Cromwell House, Highgate.—Fee for three months' attendance, £2 2s.; perpetual, £3 3s. There are now 200 beds, besides 52 additional at the convalescent branch, and it is probably the largest institution of the kind in the world. The practice of the hospital is open to pupils of the different hospitals and medical schools of London and medical practitioners on conditions to be ascertained from the Secretary.

EYE HOSPITAL.

ROYAL LONDON OPHTHALMIC HOSPITAL, formerly in Moorfields, and recently rebuilt in the City Road, is the largest hospital devoted to this specialty in Great Britain, and contains 138 beds. Students and practitioners are admitted to the practice daily at 9 o'clock.

Operations, 10 o'clock and after. Fee for six months, £3 3s.; perpetual, £5 5s. Further particulars of the Secretary.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, adjoins Charing Cross Hospital in King William Street. It has about 34 beds and a very large out-patient clinic. The lectures and demonstrations are arranged with special reference to the requirements of practitioners and senior students. Fee, six months, £3 3s.; perpetual, £5 5s.

ROYAL EYE HOSPITAL, St. George's Circus, Southwark.—There are two beds and two cots. Fee, £2 2s. for three months, £3 3s. for six months, and £5 5s. perpetual. Courses are held on ophthalmoscopy, refraction, and diseases of the eye; fee, £1 1s. for each course, but pupils may attend each course once without extra fee. Pathology class, £1 11s. 6d. to cover cost of materials.

SKIN HOSPITALS.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.—Out-patient department, 49 Leicester Square; In-patient department, 238 Uxbridge Road, Shepherd's Bush. This hospital has a well-equipped in-patient department, with 50 beds. It has a School of Dermatology at 49 Leicester Square, which is conducted by the medical staff of the hospital. A spacious laboratory is also provided. During the past year the free course of Chesterfield Lectures given by Dr. Morgan Dockrell has proved a great success, being well attended by the profession. The next course (free) will commence in October next, and the dates and times will be duly announced in our columns. (See advt.)

One of the oldest institutions of the kind is the Western Skin Hospital (Welbeck Street, W.), which was started as long ago as 1851. The practice of the hospital is open to students and practitioners. Students of this specialty have also the "London Skin Hospital," in Fitzroy Square, with seven beds and an out-patient department of over 400. There are also the Stamford Street Skin Hospital, in the south-east part of the Metropolis, with 10 beds and an out-patient department of 5,000, so that the students' needs in this direction are well catered for.

LONDON TEMPERANCE HOSPITAL.—The hospital contains 110 beds, and is conducted as its name implies on non-alcoholic principles by an excellent staff. The medical and surgical practice is open to students and practitioners. Appointments (vacancies for which are advertised in the medical journals): Surgical and medical registrars, resident medical officer, and one assistant resident medical officer.

METROPOLITAN HOSPITAL, Kingsland.—This was until recently known as the Metropolitan Free Hospital, is situated in the north-eastern district of the Metropolis, and contains 160 beds. It is a general hospital, with various special departments for the treatment of diseases of the eye, throat, ear, &c.

TOTTENHAM HOSPITAL, N.—This hospital contains medical and surgical wards and a ward for children, having in all 73 beds. There are special departments for gynaecological cases, diseases of the eye, ear, throat, and nose, and skin diseases. It has now been authorised by the University of London to give certificates of post-graduate study for the M.D. and M.S. degrees.

METROPOLITAN POST-GRADUATE INSTITUTIONS.

MEDICAL GRADUATES' COLLEGE AND POLyclINIC.—This institution affords to medical men special facilities for acquiring technical skill, and advancing their medical and scientific knowledge. The building, which is large and commodious, is situated at 32 Gower Street, and contains lecture and consulting rooms, pathological and clinical laboratories, Röntgen ray room, an ophthalmoscopy room, a library and museum, and reading and smoking rooms. Clinics, at which patients are shown, are given every day of the week except Saturday, at 4 p.m. Clinical lectures are delivered on alternate Wednesdays at 5.15 p.m., and systematic lectures on special subjects are delivered.
twice a month, on Monday and Friday evenings, at 5.15 p.m. Four sessions of practical classes, each lasting six weeks, and a vacation session of three weeks' duration are held during the year, the subjects taught comprising ophthalmology, otology, clinical microscopy, laboratory and some new diseases and practical X-ray work. There are, in addition, extra-mural classes in operative surgery, bacteriology, and public health.

A complimentary ticket for three days, admitting to clinics and lectures, is issued to any medical practitioner on personal application at the college. The annual subscription for practitioners residing in Great Britain and Ireland is one guinea, and for practitioners residing in the United States of America, a half a guinea. Full information may be obtained from the medical superintendent, Mr. Hayward Pinch, F.R.C.S.

WEST LONDON POST-GRADUATE COLLEGE.—The West London Hospital, Hammersmith, contains 175 beds; the Post-Graduate course was started in 1897. Instruction is given in the out-patient department daily at 2.15 p.m., by assistant physicians and assistant surgeons, and post-graduates can accompany members of the staff on their daily visits to the wards.

There are special departments for diseases of the eye; the ear, throat, and nose; the skin; for diseases of women; medical diseases of children; and for orthopaedic and X-ray work. Clinical assistants, appointed from among the post-graduates. Practical classes for instruction in these subjects are held each session.

Practical lectures and demonstrations are given each afternoon (except Saturday), at 5 p.m., during the session.

Fees.—The fee for the hospital practice, including all the ordinary demonstrations and lectures, is £1 1s. for one week; £2 2s. for one month; £6 4s. for three months; £10 10s. for six months; £15 10s. for one year; and £21 for a life ticket; all fees to be paid in advance. Attendance on either the medical or surgical practice alone may be taken out for the fee of £3 3s. for three months. The fee for three months' attendance in any one special department, other than medicine or surgery, is £2 2s. Further information can be obtained from the Dean at the West London Hospital.

NORTH-EAST LONDON POST-GRADUATE COLLEGE.—At the Tottenham Hospital, N., facilities are afforded to qualified medical men for taking part in the work of an active hospital for general and surgical wards and demonstrations of various branches of medicine, surgery, and gynaecology, with opportunities for clinical instruction, instruction in medicine, the skin, nose, and throat. Clinical lectures are given from time to time by members of the staff. Courses are demonstrated both in the wards and in the various out-patient departments; operations are performed every afternoon of the week, except Saturday. The fee for a three months' course of study, which may be begun at any time, in any single department, is one guinea. A fee of two guineas admits the whole practice of the hospital for a similar term, and a perpetual ticket for the practice of the hospital may, for the present, be obtained on payment of a fee of three guineas. Additional information can be obtained from the Dean at the Post-Graduate College, Tottenham.

PROVINCIAL MEDICAL SCHOOLS.

BRISTOL UNIVERSITY COLLEGE.—FACULTY OF MEDICINE.—The lectures and instruction given in the Faculty of Arts and Science of University College, Bristol, are adapted to the various preliminary examination work, and clinical and laboratory work, and are designed for the examination of the Army and Navy Boards. Students of the Faculty are admitted to the clinical practice of those very important and well-equipped institutions, the Bristol Royal Infirmary and the Bristol General Hospital. The infirmary and the hospital comprise between them a total of 470 beds, and both have very extensive outpatient departments. Special departments for the diseases of women and children, and of the eye, ear, and throat, besides large outdoor maternity departments and dental departments. Students of the college also have the privilege of attending clinical practice at the Bristol Royal Hospital for Sick Children and Women, containing 104 beds, and that of the Bristol Eye Hospital, with 40 beds. The total number of beds available for clinical instruction is therefore 614. Very exceptional facilities are thus offered to students for obtaining a wide and thorough acquaintance with all branches of medical and surgical work.

Appointments.—At the Royal Infirmary, now incorporated for teaching, and also at the Hospital, clinical clerks and dressers reside in the house in weekly rotation. A pathological clerk is appointed every three months. Also obstetric clerks and ob- the infirmary. These appointments are given as follows:

Scholarships, Prizes, &c.—Prizes and certificates of honour are given in University College in all the subjects of the curriculum. There are four entrance scholarships, valued at £50 each, one Martyns' memorial scholarships (pathology and morbid anatomy) of £10 each, the Tibbits' memorial prize, value £5, for proficiency in surgical practice, Henry Swinley's fellowships, £20, £10, £5 each, and the Victoria University Scholarship, £50. The Victoria University Scholarship, £22 10s. 6d.; one gold and silver medal awarded by the committee, and various prizes for clinical work in surgery and medicine.

Fees.—School fees for attendance on all courses of lectures, except comparative anatomy, 6s. guineas, or 55 guineas. Dental composition fee, 55 guineas. Clinical fees—Surgical practice, one year, 12 guineas; perpetual, 20 guineas. Medical practice, 20 guineas; perpetual medicine and surgery, 35 guineas; clerk or dresser, 5 guineas; obstetric clerk, 3 guineas.

Prospectus and further information on application to the Dean, Professor E. Markham Skerritt.

YORKSHIRE COLLEGE OF MEDICAL SCHOOLS, LEEDS.—This school was originally founded seventy years since as the Leeds Medical School, but it now forms the medical department of Yorkshire College, one of the constituent colleges of the Victoria University. The building, erected on a site contiguous to the infirmary, and opened five years ago, contains one of the finest dissecting rooms in the Kingdom, extensive laboratories for physiology and pathology, with the most recent improvements in fitting up and room accommodation, a large library, and separate museums for physiology and anatomy. Professors and lecturers are attached, and the clinical teaching is given by the physicians and surgeons of the infirmary. Ophthalmic demonstrations and demonstrations of skin diseases are given in the infirmary by surgeons in each department, where also are obtainable various clinical clerkships, dresserships, and other appointments; and an externship is attached, at which the necessary attendance at labour can be taken; besides the infirmary there is a large dispensary, a large hospital for infectious diseases, and a hospital for women and children, all of which are open to students of the school.

Scholarships, Prizes, &c.—(1) A Gilchrist scholarship of £50 a year for three years is awarded annually. (2) A University scholarship of £55 (awarded annually). (3) An entrance scholarship of 64 guineas. There are also a Hardwick prize in clinical medicine, a M'Gill prize in clinical surgery, each of the value of £10, and Thorpe prizes of £10 and £5 in forensic medicine and hygiene, and a Scuttgood prize in midwifery, besides the silver and gold medals and other class prizes. The composition fee for attendance upon all the required courses of school lectures is 64 guineas for University students who have attended the preliminary scientific courses, and the same fee for University students, exclusive of chemistry and biology.

At the General Infirmary, containing 447 beds, the perpetual fee for medical and surgical practice and clinical lectures is £42 in one sum, or two instalments of £21 each.
of £2 each. These fees are not included in the composition fees for lectures, and are payable separately.

A scholarship of £42 to cover the cost of medical and surgical practice is offered annually by the Infirmary. M.C. G. OWEN, M.D. COLEGEO SCHOOL OF MEDICINE, VICTORIA UNIVERSITY.—The medical school buildings, which include large laboratories, dissecting-rooms, library and reading-rooms, are on the most modern principles, and students wishing to engage in anatomical, physiological, or pathological research will find excellent opportunity for study in the complete and well-furnished laboratories. Hospital practice is taken out at the Royal Infirmary, which contains 300 beds, and the Countess of Chester Lunatic Asylum, the General Hospital, the Southern Hospital, and other special hospitals also afford teaching facilities of great importance.

Appointments.—The following appointments are made in connection with the Manchester Royal Infirmary:—Surgical registrar, at £30 per annum; a pathologist registrar, at £100 per annum; a medical registrar, at £70 per annum; two assistant medical officers, each at £50 per annum; a resident medical officer at the Convalsescent Hospital, Cheadle, one year, £150 per annum; resident medical officer, one year, £150; resident surgical officer, one year, £150 per annum. Chiroformists, annually, at £50, to be paid to the present house surgeons and one house physician are appointed every three months for a term of six months; a resident assistant at the Convalsescent Hospital, Cheadle, appointed every six months.

Scholarships.—Dalton entrance scholarships, £40 per annum for two years; Cartwright entrance scholarships, £35 per annum for three years; Heine entrance scholarship, £35 per annum for three years; Rogers entrance scholarship, £40 per annum for two years; Seaton entrance scholarship, £40 per annum for two years; James Gaskell entrance scholarship, £40 per annum for two years; Kay Shuttlesworth (Sir Jas. Platt), £40 per annum for three years; Theodore's modern languages exhibition, £15; Honorary Research Fellowships; Entrance scholarships in Medicine, £100 (towards College and Infirmary fees); Manchester Grammar School scholarship, £18 per annum for three years; Turner scholarship of £20 to students who have completed four years of study in the College; Platt physiological scholarship, value £50, tenable for two years, open to students between the ages of 16 and 25; Platt physiological scholarship, £50; one Professor Tom Jones exhibition in anatomy of £25; one Professor Tom Jones memorial surgical scholarship of £100, awarded triennially; two Platt exhibitions, £50, for the first and second years' students in physiology; Sidney Renshaw physiological exhibition, £15; Dumville surgical prize, £15, at the end of the winter session; two Dauntsey medical entrance scholarships, value £50, tenable for one year. John Henry Aspinall scholarship in diseases of children, value about £30, awarded annually; Gilchrist scholarships of £50 per annum tenable for three years in any of the Colleges of the Victoria University, awarded to the candidate gaining the highest number of marks in the first division of the preliminary examination of the Victoria University; the Bradley memorial scholarship, £20, in clinical surgery is offered annually in the summer session to candidates who must be fourth-year students; one medical and one surgical clinical prize are also offered annually.

Fees.—Composition fee, £70, in two sums of £35 each. Hospital practice: composition fee, £42, or two installments of £21 each. Medical Fees.—Composition fee, £50, payable in two sums of £25 each. Hospital practice, £21.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-ON-TYNE.—A very commodious and ornate new building has been erected here at a cost of about £31,000. The Royal Infirmary, at which clinical instruction is obtained, contains 280 beds. Pathological demonstrations are given as opportunity offers. Practical work can be studied in the Newcastile Hospitals. Opportunities for practical study are also afforded by the Dispensary, City Infectious Diseases Hospital, Eye Infirmary, and at the Northumberland County Lunatic Asylum.

Appointments.—Assistant demonstrators of anatomy receiving each an honorarium; prosecutors for the post of demonstrator of physiology and pathology; assistants to the dental surgeon, clinical clerks, and dressers are appointed at regular intervals. One year's attendance at the College is required on the part of candidates for the degrees in medicine of the University of Durham.

Scholarships, &c.—University scholarships, value £100, for proficiency in arts, awarded annually at the beginning of winter session to full students in their first year. The Robert Colenutt scholarship, £20, and the Charles Clark memorial scholarship, £20 (the interest of £400 with a gold medal) for medicine, surgery, midwifery, and pathology, open to full students who have passed the primary examination of a licensing body. The Tulloch scholarship, interest of £50 annually, for anatomy, physiology, and chemistry. The Charlton memorial scholarship, interest of £700 annually, open to full students entered for the class of medicine, at the end of the fourth or fifth winter. The Gibb scholarship, interest of £500 annually, for pathology, at end of summer session. Goyder memorial scholarship in clinical medicine and clinical surgery, proceeds of £125 annually. The Luke Armstrong memorial scholarship, the Stephen Armstrong memorial scholarship in surgery, interest on £1,000. The Heath scholarship in surgery (the next award will be in 1904); the interest on £4,000 is awarded every second year. The Gallon prize in midwifery, the interest of £25 is awarded to children; the interest on £25 is awarded yearly. At the end of the year a prize of books is awarded in each of the regular classes.

Fees.—(a) A composition ticket for lectures at the college may be obtained—1. By payment of 72 guineas on entrance. 2. By payment of 46 guineas at the commencement of the first sessional year and 36 guineas at the commencement of the second sessional year. 3. By payment of 36, 31, and 20 guineas, respectively, at the commencement of the sessional year. (b) Fees for attendance on hospital practice: For three months' medical and hospital practice, five guineas; for six months, eight guineas; or by three instalments at the commencement of the sessional year, viz., first year, 12 guineas; second year, 10 guineas; third year, six guineas; or by two instalments, viz., first year, 14 guineas; second year, 12 guineas.

UNIVERSITY COLLEGE, SHEFFIELD MEDICAL DEPARTMENT.—The medical department contains a medical library, good class-rooms, an excellent anatomical department, and every provision for medical education that can be desired. The course of study in the department is founded on the teaching of a very high standard of physiology consists of a lecture and demonstration theatre, students' laboratory, preparing room and galvanometer room, all of which are equipped with the most modern apparatus. The pathology department is in a separate temporary building. It contains a pathological museum and laboratory, and a bacteriological laboratory, which has been completely equipped through the generosity of "A Sheffield Citizen." The course of lectures and instruction is adapted to meet the requirements of the various examining bodies. Full courses of instruction required for the D.P.H. are given. The new dental department has been recognised by the teaching body. Students at this college obtain medical and surgical practice at the Royal Infirmary, containing 247 beds, and also at the Sheffield Royal Hospital, containing 160 beds. The fees for attendance, 60 sh., each for medical and surgical practice, and the fees for the winter session, and for three months £3 3s. each. Perpetual fee for medical and surgical hospital practice in a single payment of £45, or in two payments, 60 sh., £25 on entrance, and £22 within twelve months' tenure of the hospital. The fees of the Jesop Hospital for Diseases of Women (80 beds), to the City Fever Hospitals, and to the South Yorkshire Lunatic Asylum at Wadsley. The winter session will commence on October 12th, and the introductory address, will be delivered by Sir Michael Foster, K.C.B., M.D., F.R.S. on October 15th.
Scholarships, &c.—An entrance scholarship of the value of £110 is annually awarded to the best candidate (if of sufficient merit) in mathematics, elementary physics, inorganic chemistry, Latin, English.

Composition fee, 60 guineas, or in two instalments of 35 guineas and 30 guineas, for lectures and practical clergies required by the Examining Board in England.

The Kaye Scholarship, for second year's students, natives of Sheffield, is awarded annually, under certain regulations. Prizes for clinical medicine and clinical surgery of 10 guineas; Simon prize in pathology, £10; poetics awarded annually.

UNIVERSITY COLLEGE, CARDIFF, SCHOOL OF MEDICINE.—This college, which is one of the colleges of the University of Wales, has since its foundation, in 1883, possessed of the University of London, and for the corresponding examinations of other licensing bodies. In 1893 Chairs of Anatomy and Physiology and a Lectureship in Materia Medica and Pharmacy were established, making it possible for students of medicine to spend three out of the five years of prescribed study at Cardiff.

Arrangements with the managing committee of the Cardiff Infirmary, to give students of the College the privilege of attending this large and well-ordered hospital, which is situated within five minutes' walk of University College. Many students, especially from Wales and Monmouthshire, avail themselves of the opportunity to pursue their studies part of their medical curriculum near home. All classes are open alike to both men and women students over sixteen years of age. The courses of instruction given at Cardiff, as well as that of the examiners of the Universities, Royal colleges, and other licensing bodies of Great Britain and Ireland. Having spent two or three years in study at Cardiff, and having passed the examinations in these years, a student may proceed to London or elsewhere and complete his qualifying course for a University degree or for a college diploma.

Students preparing for the first and second examinations of the Joint Board for England, or for the corresponding examinations of the Joint Board for Scotland, or for those of the Society of Apothecaries, may compound for their classes by paying a single composition fee of £60, or by paying £18 10s. and £24 10s. at the beginning of their first and second years respectively. Those preparing for the preliminary scientific and intermediate examinations in medicine of the University of London may compound for their three years' instruction at Cardiff by paying a single composition fee of £57 10s., or by paying £13 13s., £28, and £21 at the beginning of their first, second and third years respectively.

In 1890 a department of Public Health was established, and lecturers in bacteriology and in public health and hygiene were appointed. Medical men preparing for a diploma in Public Health and Hygiene can attend the complete courses of lectures and laboratory instruction in this department. These courses are recognised by the University of Cambridge, by the Royal Colleges of Physicians and Surgeons, and by Victoria University.

Scholarships, &c.—The attention of students about to matriculate is drawn to the numerous entrance scholarships for exhibitions which are offered at the college for competition in September, most of which may be held by both men and women students. Full particulars of the examination for these may be obtained from the Registrar.

LIVERPOOL ROYAL SOUTHERN HOSPITAL.—The clinical pressure on this hospital is situated within convenient distance of the Liverpool University, and affords every facility for clinical and pathological study. The hospital contains 200 beds, and in addition to the general medical and surgical cases, special attention is devoted to diseases of women and children. There is a special ward for tropical diseases in connection with the University laboratories.

Medical and surgical staff visit the wards daily, and the ward instruction is supplemented by weekly clinical lectures. Additional have been made to the teaching staff so that students may now obtain instruction in diseases of the eye, ear and throat. Demonstrations in the use of the X-ray apparatus are given at intervals. There is an excellent pathological department, with laboratory attached, where demonstrations are arranged for and regular instruction is given in practical pathology. The practice of St. George's Hospital for Diseases of the Skin is free to students, and thus ample opportunity is afforded for acquiring a knowledge of dermatology. In addition to the clinical clerkships which are allotted to the students at the resident posts of assistant physicians, the students whom the board may think most suited to hold them every three months. The Alexander Fellowship in Pathology of £100 a year is open to students of this school; three prizes of £5 each are also awarded to the best taken series of medical and surgical cases.

Fees:—Perpetual, £26 5s.; one year, £10 10s.; six months, £7 7s.; three months, £4 4s.

There are rooms for a limited number of resident students: terms (exclusive of fee for hospital practice), £15 15s. per quarter. The practice of the hospital is recognised by all examining bodies.

LIVERPOOL SCHOOLS OF TROPICAL MEDICINE.—This school, which has for its object research into Tropical Diseases and Improvement in Tropical Sanitation, was founded in Liverpool in 1899 by Sir Alfred Jones, K.C.M.G., who is the chairman of the school. The research work of the school is carried on in the School of Tropical Medicine and in the laboratory in Liverpool University. The clinical work is carried on at the Royal Southern Hospital. A special feature of the work of the Liverpool School of Tropical Medicine has been the dispatch of a large number of important medical expeditions to various places in the tropics, especially West Africa. Although the School has only been in existence for a short time it has already sent out a dozen of these expeditions.

In addition, the School has issued a number of valuable publications and monographs on subjects connected with tropical diseases, which can be obtained from Messrs. Longman, Green and Co., The Dukes of Northumberland, K.G., and Mr. William Adamson are Vice-Chairmen of the School, and the following is the Staff:—The Sir Alfred Jones Professor of Tropical Medicine, Major Ronald Ross, C.B., R.F.S., R.F.C.; Walter Myers Lecturer, Dr. J. W. W. Stephens, M.D.; Walter Myers Fellow, Dr. J. E. Dutton; Assistant Lecturers, Dr. A. S. Grünbaum, Dr. Fielding Ould, Dr. Balfour Stewart, Dr. H. R. Christy, A. H. Milne, A. (Cantab.), Hon. Secretary.

The following are the principal provincial hospitals having the greatest number of beds, to which students are admitted where clinical instrucn can be obtained, but to which there is no medical school attached:—

BATH ROYAL UNITED HOSPITAL.—This is a well-appointed hospital in the West of England, with 130 beds, at which students can obtain clinical instruction. The hospital is recognised by the Colleges, and is licensed for dissection. It contains also an excellent museum and library. Fee for six months' attendance, five guineas; twelve months', ten guineas.

BRADFORD INFIRMARY.—The hospital contains 210 beds. Non-resident pupils are received—and abundance of clinical material is obtainable. One year's attendance is recognised by the Examining Board. Fee, perpetual, £10 10s.

BRIGHTON SUSSEX COUNTY HOSPITAL contains 190 beds. It is recognised by the College of Surgeons and by the Joint Board. Out-patients are admitted to the clinical teaching and the classes at a fee of £21 for two years.

LIVERPOOL NORTHERN HOSPITAL contains 155 beds. Clinical instruction is given by the staff during the summer and winter sessions. Clinical clerkships and assistant clerkships are open to all students who pay fees. Fees for hospital attendance; Perpetual, £26 5s.; one year, £10 10s.; six months, £7 7s.; three months, £4 4s.; practical pharmacy, £2 2s.
NORFOLK AND NORWICH HOSPITAL.—This hospital is recognized by the Colleges, and contains 220 beds. Fees, £10 10s. for six months, £15 15s. for twelve months' medical and surgical practice. Pupils, resident and non-resident, are admitted.

NEATHAMPTON GENERAL INFIRMARY.—The number of beds is 165. Out-patients are received, and have every opportunity of acquiring a practical knowledge of their profession. Instruction is also given in anatomy and materia medica and practical pharmacy. Non-resident pupils are taken at a fee of £10 10s.

ROYAL BERKSHIRE HOSPITAL.—The town of Reading, at which this hospital is situated, has a very large working-class population, and excellent opportunities for instruction in the wards and for the study of pathology. Non-resident pupils are admitted for a fee of £10 10s.

The Royal Hospital, Portsmouth.—The hospital is a preparatory school of medicine and surgery, and the attendance of pupils is recognized by the Examining Boards. The number of beds is 150 and during last year there were 1,103 in-patients and 9,101 out-patients. Fees: £6 6s. per month, with the privilege of the Royal Hospital Exeter. The hospital contains 218 beds (including special wards, and a good library, museum, dissecting room, and post-mortem room. Attendance on the practice of this hospital qualifies for all the Examining Boards, and examinations can be made which students can attend midwifery on application to the House Surgeon.

WOLVERHAMPTON GENERAL HOSPITAL.—The hospital has 305 beds, all of which are attended to by resident surgeons. Fees: Six months, £8 6s.; twelve months, £12 12s.; perpetual, £21.

The ENGLISH UNIVERSITIES.

The English Universities are six in number, viz., Oxford, Cambridge, London, Edinburgh, St. Andrews, and the recently created University of Birmingham. The choice of a University is usually determined by social, geographical, and financial considerations. Evidently students whose parents are able and willing to incur the necessary expense would do well to select one or other of the ancient Universities, since their degrees confer upon their holders a status not accorded by the pupils of the newer educational institutions. To those less favoured by fortune, but blessed with energy and a fair share of intelligence, the London University offers ample scope, and its degrees are recognised as the outward and visible sign of high professional attainments. The Victoria University comprises Owens College, Manchester; University College, Liverpool; and the Yorkshire College at Leeds. It thus covers a wide area and attracts considerable numbers of students whose aim is the possession of a degree in medicine.

OXFORD.

There are two degrees in medicine, M.B. and M.D., and two degrees in surgery. The M.B. and B.Ch. degrees are granted to those members of the University who have passed the second examination. Graduates in Arts, B.A., are alone eligible for these two degrees. In order to obtain the degree of M.B., a candidate must first pass the following examinations:—1. Preliminary: Subjects:—Mechanics and physics, chemistry, zoology, and botany. 2. Professional: (a) First examination (held twice a year): Subjects:—Surgical chemistry and materia medica. (b) Second examination: Subjects:—Medicine, surgery, midwifery, pathology, forensic medicine with hygiene. The approximate dates of the examinations are as follows:

Preliminaries:—Mechanics, physics, and chemistry, December and June; Zoology and botany, December and March; Professional (First and Second M.B.), June and December.

The degree of M.D. is granted to Bachelors of Medicine of the University who have entered on their thirty-ninth term on the condition of having been approved of by the appointed professors and examiners. The degree of M.Ch. is granted to Bachelors of Surgery of the University who have entered their twenty-seventh term, who are members of the surgical staff of a recognised hospital, or have acted as dresser or house surgeon in such a hospital for six months, and who have passed an examination in surgery, surgical anatomy, and surgery extemporaneous. This examination is held annually in June, at the end of the Second M.B. Examination.

The First examination for the degrees of M.B. and B.Ch. may be passed as soon as the Preliminary Scientific examinations have been completed. The subjects of this examination may be presented separately or in any combination or in any order, provided anatomy and physiology be passed together.

The Second examination may be passed at any time after the completion of the first. The subjects of medicine, surgery, and midwifery must be passed at the same examination, but candidates are allowed to present themselves in pathology and physiology at a separate examination.

Diploma in Public Health.—An examination, which will yearly in Michaelmas Term, open to all registered medical practitioners. No one is admitted as a candidate unless his name has been on the "Medical Register" for twelve months.

Scholarships, &c.—Scholarships in some branch of natural science (chemistry, physics, biology), of the average value of £50 per annum, tenable for four years, and renewable under certain conditions for a fifth year. As well as exhibitions of less annual value, are awarded after competitive examinations every year by some of the Colleges. Notices of vacancy, &c., are published in the "University Gazette." In February there is competed for annually, by those who, having obtained a first-class in any school (moderations or final), or a scholarship or prize open to general competition in the University, have passed all the examinations for the degree of B.A. A Radcliffe Travelling Fellowship is tenable for three years, of the annual value of £200. The examination is partly scientific, partly medical. A Rolleston Memorial prize is awarded once in two years to encourage the study of medicine, and Cambridge of not more than ten years' standing for an original research in some biological subject, including physiology or pathology.

More detailed information may be obtained from the "Examination Statutes" with the "Regulations" for the current year, published annually in June by the Clarendon Press, price 1s.

CAMBRIDGE.

At the University of Cambridge five years of medical study are required for M.B. and B.C. degrees. The candidate must have resided nine terms (the fifth) in the University, and have passed the "previous" examination in classics and mathematics. There are three parts of examinations: The first in anatomy and physiology; the second in human anatomy and physiology; and the third in (1) pharmacology and general pathology, (2) in surgery, midwifery, and medicine. The first and the third examinations are divided into two parts, which can be taken separately. Subsequently to the third examination an Act has to be kept which consists in reading an original thesis, followed by an oral examination on the subject of the thesis. As the candidate for the examination for the degree in surgery are included in the third examination for the M.B. degree, candidates are admitted to the degree of Bachelor of Surgery on passing the third examination for Bachelor of Medicine.

The M.D. degree may be taken three years after the M.B. An Act has to be kept, with oral examinations and an essay to be written extemore. There is also the degree of Master of Surgery, for which the candidate.
having already passed for B.C., or being M.A., has otherwise qualified in surgery, has to pursue extra study in surgery, and has a special examination or submits original contributions of merit to the science or art of surgery. The yearly expenditure of a student who has a by inspection fee of £150 to £200 a year. This, however, may include all payments to the University and the College—all fees as well as clothes, pocket money, traveling expenses, &c. Non-collegiate students have only to pay the University fees, which are not large. They lodge and board as they like; their expenses, therefore, are entirely in their own hands.

The University degree grants a diploma in public health without the necessity of residence, the examination being in so much of State Medicine as is comprised in the functions of officers of health, and subject to the latest requirements of the General Medical Council. These examinations are held in Cambridge the first week in April and October. Candidates, whose names must be on the "Medical Register" of the United Kingdom, and need not be members of the University, should send in their applications to the Secretary of the State Medicine Syndicate a fortnight in advance. Every candidate who has passed both parts of the examination to the satisfaction of the examiners will receive a testimonial, testifying to his competent knowledge of the subjects comprised in the duties of a medical officer of health.

An abstract of all Regulations may be obtained upon sending a stamped directed envelope to the Assistant Registrar, Cambridge. Full information is contained in the University Calendar.

UNIVERSITY OF LONDON.

The Medical Faculty grants the degrees of Bachelor of Medicine and Surgery, Doctor of Medicine and Master in Surgery. Under the new regulations the students are divided into "Internal" and "External." An internal student is one who has matriculated at the University and is studying in a school approved by that body, or under the teachers of the University. An external student is one who has adopted an alternative course of study. The regulations differ somewhat as to their application to the two groups of students. We only propose to deal with them as they affect internal students, since the special information required by the others has best be obtained directly from the Registrar. Under no circumstances will a student be admitted to the final examination for a degree until at least three years has elapsed since matriculation or other examination entitling to registration as a medical student.

The Matriculation Examination will take place twice a year—January, June (or July), and September. Application for admission to it must be made on a special form about six weeks beforehand, and the candidate must have completed his 16th year at the date of the examination. Candidates must show a competent knowledge of five subjects, among which must be English and elementary mathematics. The other three (one of which a language) may be selected from the following:—Latin, Greek, French, German, Arabic, Sanscrit, Spanish, Portuguese, Italian, Hebrew, Ancient History, Modern History, Logic, Physics, and General Geography, Geometrical and Mechanical Drawing, Mathematics (more advanced than in the compulsory examination), Elementary Mechanics, Elementary Chemistry, Elementary Biology.

* May obtain registration as Internal or External students on presentation of documentary evidence as to their condition and a payment of £25: Graduates of such British, Colonial, and foreign Universities as are approved by the Senate for that purpose, and those who have passed the examinations for a degree in those Universities, also women who have obtained Tripos certificates granted by the University of Cambridge, women who have obtained certificates showing that, under the conditions prescribed by the Delegacy for Local Examinations in Medicine, they have passed the Local Public Examination of that University or have obtained honours in the Oxford University Examination for Women in Modern Languages, and students who have passed the Second Class Certificate of the Scotch School Leaving Certificate, having passed the Ordinary examination, and those who hold the Zeugniss der Reife from a Gymnasium or Realschule within the German or Austrian Empire, or the Maturitaetskunstzeugniss of a Swiss Gymnasium or Oberrealschule, or the Eidgenoische Maturitaetskunstzeugniss of Switzerland.
Candidates who have passed the First and Second Examinations of the University will be exempt from the First and Second Examination of the Conjoint Board.

For the degree of Bachelor in Surgery (B.S.) every candidate must have passed the examination for the degree of Bachelor of Medicine of the University of Durham, and must have attended one course of lectures on operative surgery, and one course on regional anatomy. Candidates will be required to perform operations on the dead body, and to give proof of practical knowledge of the use of surgical instruments and appliances.

For the degree of Master in Surgery (M.S.) candidates must not be less than twenty-five years of age, and must satisfy the University as to their knowledge of Greek. In case they shall not have passed in this subject at the Preliminary Examinations in Arts for the M.B. degree, they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.S. They must also have obtained the degree of Bachelor in Surgery of the University of Durham, and must have been engaged for at least two years subsequently to the date of acquisition of the degree of Bachelor of Medicine in attendance on the practice of a recognised hospital, or in the naval or military service, or in medical or surgical practice.

For the degree of Doctor in Medicine (M.D.) candidates must be of not less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek. In case they shall not have passed in this subject at the Preliminary Examinations in Arts for the M.B. degree, they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.D. They must also have obtained the degree of Bachelor of Medicine of the University of Durham, and must have been engaged for at least two years, subsequently to the date of acquisition of the degree of Bachelor of Medicine, in attendance on the practice of a recognised hospital or in the naval or military services, or in medical or surgical practice.

Each candidate must prepare an essay, which must be typewritten, based on original research or observation, on some medical subject selected by himself, and approved by the Professor of Medicine, and must pass an examination thereon, and must be prepared to answer questions on the other subjects of his curriculum, as far as they are relevant to the essay which he has submitted.

For regulations for degrees in hygiene and for the diploma in Public Health see Calendar 1903-4.

Candidates for any of the above degrees must give at least twenty-eight days’ notice to the Secretary of the College of Medicine, Newcastle-upon-Tyne, of the date of the M.D. (Essay) Examination, candidates must send in their essays six weeks before the date of the examination.

Residence can be had in a separate hostel for female students at moderate inclusive fees for board, &c., particulars of which and any other college information will be given on application to Prof. Howden, Secretary, University of Durham College of Medicine, Newcastle-upon-Tyne.

VICTORIA UNIVERSITY OF MANCHESTER.

Candidates for degrees in medicine and surgery must attend classes in one of the colleges of the University during at least two years.

The degrees in the Faculty of Medicine are Bachelor of Medicine (B.M.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). All candidates for degrees in medicine and surgery are required to pass the Preliminary Examination, or to have passed such a previous examination as may from time to time be recognised for this purpose by the University.

The subjects of the Preliminary Examination are—
present which has been obtained from the Board of Studies. Notice of intention to present either Italian or Spanish must be given before March 1st in each year.

Before admission to the degrees of Bachelor of Medicine or Bachelor of Surgery candidates are required to pass the usual certificates of age and study as at the other Universities.

All candidates for these degrees must pass three examinations, namely—The First Examination; the Second Examination; and the Final Examination.

First Examination.—The subjects of the examination are, 1, Chemistry; 2, Elementary biology; 3, Physics.

Candidates must have attended, during at least one year, courses of both lectures and laboratory work in each of the above-named subjects.

Second,—1, Anatomy; 2, Physiology (including physiological chemistry and histology); 3, Materia medica and pharmacy.

Candidates must have passed the First Examination, and have attended courses of instruction in anatomy (systematic and practical) during two winter sessions and one summer session, in physiology for two winter sessions, in materia medica and pharmacy for one summer session. Candidates may present themselves separately in (a) anatomy and physiology, (b) materia medica and pharmacy.

Final.—The examination is divided into two parts, which may be passed separately or on the same occasion, but the first part cannot be taken before the end of the third year, and the second part cannot be taken less than two years after passing Second M.B., or before the fifth year of medical study in accordance with the University regulations. The subjects of examination are as follows: 1, Pharmacology and therapeutics; 2, General pathology and morbid anatomy; 3, Forensic medicine and toxicology and public health; 4, Obstetrics and diseases of women; 5, Surgery, systematic, clinical, and practical; 6, Medicine, systematic and clinical, including mental diseases and diseases of children. Candidates may select as a first part of the examination two or three of the subjects 1, 2, and 3.

The certificates required from candidates at the final examination are practically the same as for the corresponding examination at the London University, and only those who have previously passed the Second Examination are admitted to it. The regulations relating to the M.D. and Ch.M. degrees can be obtained on application to the Registrar.

The preliminary examination, £2; for any subsequent examination, £1. First Examination, £5; for any subsequent examination, £2. The fees for the Second Examination, for the Final Examination, and for the examination for the degree of Ch.M. are the same as for the First Examination. A fee of £10 is payable on the conferring of the degree of M.D., a fee of £4 on the conferring of the degree of Ch.M.

The Preliminary Examination is held in June and about the end of September. The first M.B. and Ch.B. is held in June; also about the end of September. The Second and Final Examinations are held in March and July, the examination for Ch.M. in July only.

UNIVERSITY OF BIRMINGHAM.

The University of Birmingham grants degrees of M.B. and Ch.M., and B.S. in the subject of Public Health. In order to obtain any of these degrees it is necessary that a student shall have passed at least the first four years of his curriculum in attendance upon the classes of the University.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—The student must have passed either the Matriculation Examination of the University or one of the following examinations, which will be accepted in lieu thereof for the present: (a) The previous examination of the University of Cambridge; (b) Responsums of the University of Oxford; (c) The matriculation examination of any other University in the United Kingdom; (d) The leaving certificate (higher) of the Oxford or Cambridge junior local examination (first or second class honours); (f) The Oxford or Cambridge senior local examination (honours); (g) The College of Preceptors examination for first-class certificate.

Matriculation Examinations are held in June and September each year.

Degrees of Doctor of Medicine and Master of Surgery.—Candidates for either of these degrees will be required either—(a) To present a thesis embodying original observations in some subject embraced in the medical curriculum and approved by a Board of Medical Examiners; or (b) To pass a general examination (written and practical) in medicine or surgery, according to the degree desired. The University also grants degrees in public health, for which ample provision has been made.

Dental Department.—The University grants the Degrees of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.).

The General and Queen's Hospitals.—The practices of these hospitals are amalgamated for the purpose of clinical instruction under the direction of the Birmingham Clinical Board, by whom all schedules will be signed and all examinations conducted. The two hospitals have a total of upwards of 400 beds, 6,000 in-patients and 80,000 out-patients are treated annually, and many valuable posts are open to students at both.

Further information can be obtained from Professor Windle, Dean, Medical Faculty.

UNIVERSITY OF LIVERPOOL.

Students may now enter for the degrees of the University of Liverpool, or may study for the degrees and qualifications of the various other licensing bodies.

Hospitals.—Students may take out their clinical work at the Liverpool Royal Infirmary, the David Lewis Northern Hospital, the Royal Southern Hospital, or the Stanley Hospital. Particulars as to fees, appointments, etc., may be obtained from the Secretaries of the Medical Boards of these institutions.

The practice of the Lying-in, Eye and Ear, Women's, Children's, Dental, and Skin Hospitals is also open to students of the Faculty of Medicine.

Fellowships and Scholarships.—Fellowships, Scholarships, and Prizes of over £100 are awarded annually. (a) A Holt Fellowship in Pathology and Surgery, of the value of £100 for one year, is awarded annually by the Medical Faculty to a senior student possessing a medical qualification. The successful candidate is required to devote a year to tutorial work and investigation in the Pathological department. (b) A Holt Fellowship in Physiology, awarded under similar conditions, also of the value of £100 for one year. (c) A Robert Gee Fellowship in Anatomy, awarded under similar conditions, of the value of £100 for one year. (d) An Alexander Fellowship for Research in Pathology of the annual value of £100, renewable. (e) A Johnson Colonial Fellowship in Pathology and Bacteriology (£100 a year, renewable). (f) A John W. Garrett International Fellowship in Physiology and Pathology (£100 a year, renewable). (g) An Ethel Boyce Fellowship in Gynaecological Pathology (£100 a year, renewable). (h) Two Lyon Jones Scholarships, of the value of £21 each for two years, are awarded annually—a Junior Scholarship, open at the end of the first year of study to Liverpool University students in the subjects of the first M.B. Examinations, and a Senior Scholarship, open to all students in the school at the end of the second or third year of study, in the subjects of Anatomy, Physiology, and Therapeutics. (i) The Derby Exhibition of £5 for one year is awarded in Clinical Medicine and Surgery in alternate years. Students may compete in their fourth and fifth years. In 1903 the subject will be Clinical Medicine. (j) The Torr Gold Medal in Anatomy, the George Howard Memorial in Physiology, the Kandt Back Medal in Pathology, the Robert Gee Book Prize, of the value of £5, for Children's Diseases, and numerous class prizes are awarded annually.

Entrance Scholarships.—Four Robert Gee Entrance Scholarships, of the value each of £25 for one year, are offered annually for competition. The holder is
required to take out the Science Course for the University Degree in Medicine.

Communications should be addressed to the Dean, Professor Benjamin Moore, M.A., D.Sc., the University, Liverpool.

**THE ENGLISH COLLEGES.**

The medical corporations in England are the Royal College of Physicians of London, the Royal College of Surgeons, £10 10s. for the whole, and the Society of Apothecaries of London. The two Royal Colleges now co-operate to hold a series of examinations, on passing which the candidate receives the diploma of Licentiate of the Royal College of Physicians (L.R.C.P.), and Member of the Royal College of Surgeons (M.R.C.S.). The Society of Apothecaries grants a complete diploma in medicine, surgery, and midwifery.

**CONJOINT EXAMINING BOARD IN ENGLAND.**

Candidates for the above licences are required to complete five years of professional study at recognised medical schools and hospitals, after passing the preliminary examination, which six months may be spent at an institution recognised by the Board for instruction in chemistry, or one year may be passed at an institution recognised by the Board for instruction in chemistry and biology, to comply with the following regulations and to pass the examinations hereinafter set forth.

**Professional Examinations.**—There are three examinations, each being partly written, partly oral, and partly practical. These examinations will be held in the months of January, April, July, and October, unless otherwise appointed, fourteen clear days' notice before the day on which the examination commences being required, the candidate transmitting at the same time the required certificates.

The subjects of the first professional examination are chemistry and physics, practical pharmacy, and elementary biology. A candidate is allowed to take this examination in three parts at different times. Rejection entails a delay of not less than three months from the date of rejection, and the candidate will be re-examined in the subject or subjects in which he has been rejected. If referred in chemistry or biology, he must produce evidence of further instruction at a recognised institution. Practical pharmacy may be passed at any time during the curriculum. Any candidate who shall produce satisfactory evidence of having passed an examination for a degree in medicine on any of the syllabus conducted at a University in the United Kingdom, India, or in a British Colony, will be exempt from examination in those subjects in which he has passed.

The fees for admission to the first examination are as follows:—For the whole examination, £10 10s.; for re-examination after rejection in Part I., £3 3s.; and for re-examination in each of the other parts, £2 2s.

A candidate referred at the second examination will be required, before being admitted to re-examination, to produce a certificate that he has pursued, to the satisfaction of his teachers, in a recognised place of study, chemical and physiological studies during a period of not less than three months subsequently to the date of his reference.

The fees for admission to the second examinations are:—For the whole examination, and £6 6s. for re-examination after rejection.

The subjects of the third and final examinations are:—Part I. Medicine, including medical anatomy, pathology, practical pharmacy, therapeutics, forensic medicine, and public health. Candidates who have passed in practical pharmacy at the first examination will not be re-examined in that subject at the third examination. Part II. Surgery, including pathology, surgical anatomy, and the use of surgical appliances. Part III. Midwifery and gynaecology. Candidates may take this examination in the three parts separately, or they may present themselves for the whole examination at one time.

Fees for admission to the third or final examination are as follows:—For the whole examination, £15 15s. Part I.—For re-examination in medicine, including medical anatomy, pathology, therapeutics, forensic medicine, and public health, £4 5s.; for re-examination in practical pharmacy at this examination, £2 2s. Part II.—For re-examination in surgery, including pathology, surgical anatomy, and the use of surgical appliances, £5 5s. Part III.—For re-examination in midwifery and gynaecology, £5 5s.

A candidate referred on the third or final examination will not be admitted to re-examination until after the lapse of a period of no less than three months from the date of rejection, and will be required, before being admitted to re-examination, to produce a certificate, in regard to medicine and surgery, of having attended the medical and surgical practice, or the medical or surgical practice, as the case may be, during the period of his reference; and in regard to midwifery and gynaecology, a certificate peculiar to women of having received, subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher.

**REGULATIONS FOR COLONIAL, INDIAN, AND FOREIGN CANDIDATES, AND UNIVERSITY CANDIDATES.**

Persons holding a Colonial, Indian, or a foreign qualification entitling them to practise medicine in the country of origin, and conferred after a course of study equivalent to those required by the Royal Colleges, are admissible to the second and third (final) examinations forthwith.

Members of a University in the United Kingdom are, under certain conditions, eligible for admission to the third (final) examination two years after passing at their University in the subjects included in the first and second examinations of the Board.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON.**

**Licentiate.**—Candidates are now subject to the regulations of the Conjoint Examining Board in England.

The following by-laws, amended in conformity with the revised regulations of the Conjoint Examining Board, were re-enacted as follows:—

"Every candidate for the College licence (unless specially exempted) shall be required to produce satisfactory evidence of having passed before the commencement of professional study a preliminary examination on subjects of general education recognised by the College.

"Every candidate shall be required to produce satisfactory evidence of having completed five years of professional study, after passing a recognised preliminary examination before admission to the final examination.

"A candidate shall not be admitted to the second examination until the completion of two winter sessions and one summer session (or 15 months during the ordinary winter sessions) at a recognised institution, or on the expiration of one winter and one summer session after passing Parts I. and III. of the first examination.

"A candidate shall not be admitted to the third (or final) examination before the expiration of five winter and five summer sessions from the date of passing the preliminary examinations and of four winter and four summer sessions after passing Parts I. and III. of the first examination." Members.—The membership of the College is granted after examination to persons above the age of 25 years who do not engage in trade, and do not and cannot practise in partnership. This diploma is only granted to persons already registered, or who have passed the final examination for the licence.

Medical graduates of a recognised University are admitted to a pass examination, but others must have
passed the examinations required for the licence of the College. The examination, which is held in January, April, July, and October, is partly written and partly oral. It is directed to medicine, and is conducted by the president and examiners. Candidates under 40, unless they have obtained a degree in arts in a British University, are examined in Latin, and either Greek, French, or German. Candidates over 40 are not so examined, and answers in medicine may in their case be modified under conditions to be ascertained by application to the Registrar. The fee for the membership is £4.2, but if the candidate is a licentiate £1.5.5 is deducted. In either case £6.6s. has to be paid before examination.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEMBERSHIP.—The candidates are now subject to the regulations of the Conjoint Board.

FELLOWSHIP.—The Fellowship of the College of Surgeons is granted after examination to persons at least 25 years of age, who have been engaged in professional studies for six years. There are two examinations—the first in anatomy and physiology, which may be passed after the third winter session; the second chiefly directed to surgery, which may be passed after six years of professional study. The second examination may be passed before attaining the age of 25, but the diploma is not granted until that age is reached. Candidates for this part of the examination must have passed the first examination. Further information can be obtained upon application to the Secretary of the Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.

There are two examinations—primary and final. The primary examination is held quarterly on the first Wednesday, and on the Monday and Tuesday in the same week, in the months of January, April, July, and October. The final examination is held monthly.

SOCIETY OF APOTHECARIES OF LONDON.

PRIMARY EXAMINATION.—This examination consists of two parts. Part I.—Elementary biology, Chemistry, Physical and the elementary mechanics of solids and fluids; Heat, Light, and Electricity. Practical chemistry, Materia medica, and Pharmacy. A synopsis indicating the range of the subjects may be obtained on application. Part II.—Anatomy and Physiology and Histology. The examination is held in January, April, July, and October.

The final examination is held monthly, and is divided into Sections I and II.

Section I consists of three parts. Part I includes: Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy, Operative Manipulations, Instruments and Appliances. Part II: (a) The Principles and Practice of Medicine, including Therapeutics, Pharmacology, Pathology, and Morbid Histology. (b) Forensic Medicine, Hygiene, Theory and Practice of Vaccination; and Mental Diseases.

Candidates passing either (a) or (b) will not be re-examined therein.

Part III. includes: Midwifery, Gynecology, and Diseases of New-born Children, Obstetric Instruments and Appliances. Candidates may enter for Parts I, II, and III. together or separately.

Section I of the Final Examination, or any part thereof, cannot be passed before the expiration of 45 months from the date of registration as a medical student.

Section 2 cannot be passed before the expiration of the fifth year.

Fees.—Primary examination, £10 10s.; final examination, £10 10s.; total fee, £21.

Further information, with particulars as to the course of study and of the certificates required, can be obtained from the Secretary to the Court of Examiners, Apothecaries' Hall, E.C.

This licence is a registrable diploma in Medicine, Surgery, and Midwifery, and qualifies the holder to compete for medical appointments in the Army, Navy, and Indian Services, also for Poor-law, Civil, and Colonial appointments.

The Gillison scholarship in Pathology is of the annual value of £50, tenable for one year, is open to Licentiates of the Society and to candidates for the diploma who obtain it within six months of election to the scholarship. An annual examination in the art of prescribing is held annually, in January, at which the following prizes are awarded:—A gold medal of the value of £6; a silver medal, and a prize of books to the two best candidates.

IRELAND—EDUCATION.

THE IRISH MEDICAL SYSTEM.

The system of medical teaching in Ireland differs from that in England in important particulars. In London each clinical hospital has its attached medical school, which is fully equipped, and which educates the students of that hospital and very seldom those of any other. In Dublin, on the contrary, the hospitals and schools are entirely separate (except that Sir Patrick Duplication of Hospitals is considerably less severe in Dublin than in London, due to the fact that the number of medical students is not so great). The Hospital of Trinity College, and a student of any hospital is free to enter for the whole or any part of his course at any hospital or hospital he pleases. As might be expected, religion, social rank, and locality of residence have their influence in causing certain classes of students to enroll to schools and hospitals suitable to their condition. But scholastic or collegiate regulations impose no restrictions as to the place of study, and as the school and hospital fees are paid in detail in Dublin, and not in a lump sum, as in London, the pupil is free to do as he pleases.

BOARD AND RESIDENCE.

There is in Dublin no organisation for domestic accommodation of medical students, save for those who are passing through Trinity College, in whose case rooms and "commons" (i.e., dinner) are provided at fixed rates. Those who can afford to pay £6 6s. or £7 7s. per month for their lodging and maintenance may find accommodation in the family of some medical man, who receives boarders, in which case they become members of the family for the time being. The majority of Dublin students, however, take a lodging in some economical locality, or they "chum" with some other student for the purpose. It is usual to contract with the lodging-house keeper for board or partial board, but some students cater for themselves.

COST OF MEDICAL EDUCATION IN IRELAND.

The cost of obtaining a medical qualification depends to some extent on the qualification sought. In this connection the following tables may be of use to the prospective student:

<table>
<thead>
<tr>
<th>COST OF MEDICAL EDUCATION</th>
<th>School</th>
<th>Cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>School of Physic, Dub. Univ.</td>
<td>£119 14s.</td>
<td></td>

<td>£124 19s.</td>
<td></td>
</tr>
</tbody>
</table>

COST OF DIPLOMAS OR DEGREES.

Qualifying Body. Cost

Dublin University: £27 (to this must be added £8 4s., the cost of obtaining an Arts degree).

Royal University: £15.

Conjoint Royal Colleges: £42.

Apothecaries' Hall: £22 18.
Thus, the absolute payment will amount to somewhere between £125 and £225 18s., according as the teaching of the Queen’s Colleges and the degrees of the Royal University of Ireland or the teaching and degrees of the Dublin University, are taken. For the Conjoint Colleges the entire cost is £166 19s., taking the minimum mode of payment. So that, assuming that extras or voluntary costs are incurred the total will vary, say, from £470 to £490. "Conjoint" usually costs £55 5s. for each of the four examinations, but if a student needs private instruction in specialist subjects he must pay extra for it.

This sum, or something like it, may be expended by the student out of his parents' funds for lectures, etc., and examinations fees, they fall due and there is no difficulty in obtaining the needful information for his guidance if he likes to pay for his course in this fashion. If, on the other hand, he prefers to pay a large sum down, he can "apprentice" himself to a teacher who will undertake all monetary responsibility for his education, and who may be able to give him some special advantage as his own pupil at hospital. This so-called "apprenticeship," is, in general, a simple contract for the payment of fees, and involves but little special teaching. All the Dublin schools require fees to be paid in advance.

DATE OF ENTRY.

The entry of names and commencement of study in Ireland is supposed to date from the 1st of October in each year, but the session really dates from the 1st of November, and the entry of names may be delayed by the dilatory to the 25th of the same month. It should, however, be recollected that no credit is given for studies or attendance until the entry is regularly made. The student must attend three-fourths of the lectures delivered, and if he loses a fortnight at the beginning he must make up for it afterwards by constant attendance.

The student begins work by attending a recognised medical school each morning at ten o’clock, and occupying his day, to five p.m., between lectures and dissections. His vacations are a fortnight at Christmas and a week at Easter, and he finally returns home at the end of June.

PRELIMINARY EXAMINATIONS.

The first act of the student is to pass a preliminary examination, without which he cannot get credit for any medical studies pursued. The next is to commence medical study. This he does by entering for lectures at a medical school. From the school registrar he gets a form, and sends it to the Branch Medical Council, 35 Dawson Street, Dublin. He is thereupon placed upon the Register of Medical Students (without fee), and his period of study counts from that date. He must register at the earliest possible moment, or he may lose credit for his work.

The only preliminary examination held specially for medical students is that held conjointly by the Royal Colleges of Physicians and Surgeons, but other examinations, e.g., the public entrance at Trinity College, the matriculation of the Royal University, the Intermediate Education passes in the required subjects, and all other examinations recognised by the General Medical Council are accepted as equivalent.

The subjects of examination as prescribed by the General Medical Council are as follows:—1. English language, including a specified author, dictation, grammar, and composition; also parsing and analysis from the book specified. 2. Latin, including grammar, translation from specified authors, and translation of easy passages not taken from such authors. 3. Elements of mathematics, comprising (a) arithmetic, including simple equations; (b) geometry, Euclid, Books I., II., and III., with easy deductions. 4. One of the following optional subjects:—(a) Greek, (b) French, (c) German. The books specified are:—1. Greek, "Iliad," by Homer, "Aeneid," by Virgil, "Julius Cæsar," by Shakespeare. 2. Latin—The first and second books of the "Aeneid," or the "Jugurthine Wars," or the third book of Livy. 3. Greek—The first book of the "Iliad," or the first book of Xenophon's "Anabasis." 4. French—Fénelon's "Télémaque." Books I., II., III. 5. German—Schiller's "Wilhelm Tell."

QUALIFICATION IN IRELAND.

The Medical Licensing Bodies of Ireland are four in number, and, as a rule, students gravitate into one or other of five classes:—a. Those who enter Trinity College, and take a full graduation in Arts in addition to their professional degrees. b. Those who take the licence of the joint Royal Colleges of Physicians and Surgeons. c. Those who take the examination at Altrincham's Hall. d. Those who take their qualifications at the Royal University of Ireland, where graduation in Arts is not necessary. e. Those who pursue their studies in Ireland, but who migrate to London, Edinburgh, or Glasgow for their licences. Almost all these last-named emigrants come from the Queen's Colleges, and the greater number of them from Belfast, while the Dublin students qualify, as a rule, in Dublin.

We do not attempt to give details as to the requisite courses of instruction for degrees or diploma, as our epigone must necessarily be insufficient for the information of the student, and we can occupy our available space with information more useful to him. The official information upon which students may depend can be obtained by sending a note to the Registrars of the Licensing Bodies or Schools.

The Irish Licensing Bodies are as follows:—

THE UNIVERSITY OF DUBLIN.

The University of Dublin grants the degrees of M.B., B.Ch., and M.A.O. to students who have obtained their degree, and who have been for at least five academic years on the books of the Medical School, and the higher degrees of M.D., M.Ch., and M.A.O. to those who have held, or have been qualified to hold, for at least three years, the grade of M.B. and B.Ch. It does not grant degrees to any but full graduates in Arts, consequently its degrees hold the highest rank of social and educational qualifications, and are sought for by those who look forward to occupying the best positions in the profession.

The expense of obtaining the degrees of M.B., B.Ch., and M.A.O. is approximately as follows:—Lectures, £54 11s. 6d.; Hospitals, £55 13s.; Degree Fees, £27.—Total, £147 4s. 6d.

The expense of the B.A., amounting altogether to £83 4s., should be added, making the total cost £230 8s. 6d.

In addition to its ordinary qualifications the University grants the following higher degrees:—

Doctor of Medicine.—To obtain this the candidate must have obtained the degree of M.B., or have been qualified to have obtained it for three years. He must then read a thesis before the Regius Professor of Medicine. Total fee for this degree, £13.

Master of Surgery.—The candidate must be a Bachelor in Surgery of three years' standing, and must then pass an examination in clinical surgery, operative surgery, surgical pathology, surgery, and surgical anatomy (on the dead subject). Fee for degree, £11.

A Master in Obstetric Science. The candidate must have passed the M.B. and B.Ch. examinations, and have completed, in addition to the courses for M.B., B.Ch., a course of obstetric medicine and surgery. He is then required to pass an examination in the following subjects:—Practice of midwifery, gynecology, anatomy of the female pelvis and elementary embryology, and clinical gynecology. Fee for this degree, £5.

Diplomate in Medicine, Surgery, and Midwifery. Candidates for the diploma in Medicine, Surgery, or Obstetric Science must be matriculated in Medicine, Surgery, or Obstetric Science must be matriculated in Medicine, Surgery, and have completed two years in Arts and five years in Medical studies. The course and examination is the same as for the diploma, except that the dissections and examinations in botany and zoology need not have been taken out or passed, and that the candidate need not
IRELAND—EDUCATION.

The Royal University of Ireland is purely an examining body. Its degrees are granted on one year's acts, i.e., the matriculation examination of this University (one other will suffice) and a first University examination at the termination of the first year. The cost of the M.B. and M.Ch. of the University, with all the necessary curriculum, is about £125. Some of the Arts examinations are conducted, not only in Dublin, but at certain county towns. The University confers the following medical degrees:

M.B., B.Ch., B.A.O., and the higher degrees of M.D., M.Ch., M.R.C.S., L.R.C.P., etc. It also confers a diploma in sanitary science and a diploma in mental diseases. All degrees are open to persons of either sex.

The University examinations are held in the spring, commencing about 20 April, and in the autumn, commencing about 20 October. All candidates for any degree must pass the matriculation examination and the first University examination. The course for the degree of M.B., B.Ch., B.A.O., extends over five years. Students will be admitted to the first University examination after one year from matriculation. Fee, £7.

The medical course consists of three previous examinations, one at the end of each year, and one degree examination at the end of the fifth year. Fee for each previous examination, £1; for the degree examination, £2; for the diploma, £10.

In addition, the following degrees are granted:

Diploma in Sanitary Science.—Conferred only on graduates in medicine of the University of at least twelve months' standing. Fee, £2. Subjects:—Climatology, chemistry, geology, physics, vital statistics, hygiene, sanitary law.

The M.D. Degree.—Conferred only on graduates in medicine of the University of at least three years' standing. They must at the same time produce a certificate of having been, for at least two academic years, engaged in hospital or private, medical, surgical, or obstetrical practice, or in the military or naval medical service. Fee, £5. The examination comprises medical diseases and the theory and practice of medicine, including pathology. Every candidate will be examined at the bedside, and required to diagnose at least three medical cases, and prescribe treatment, and to write detailed reports on at least two cases to be selected by the examiners and to discuss the questions arising therefrom.

The M.Ch. Degree.—Conferred only on graduates in medicine of the University of at least three years' standing, and who can produce a similar certificate of practice to that required for the M.D. degree. Fee, £5.

The examination comprises surgery, both theoretical and operative; surgical anatomy; ophthalmology and otology.

The Mastership of Obstetrics.—Conferred only on graduates in medicine of the University of at least three years' standing, and who can produce a similar certificate of practice to that required for the M.D. and M.Ch. degrees. Fee, £5.

The examination comprises midwifery and diseases of women and children.

Prices, &c.—First examination in Medicine. Two first-class exhibitions of £20 each, and two second of £10 each.

Second Examination in Medicine.—Two first-class of £25, and two second-class of £15, and the Dr. Henry Hutchinson, Stewart Medical Scholarships, value £10. The Dr. Henry Hutchinson, Stewart Medical Scholarships in psychological medicine, diseases of the nervous system, and anatomy, physiology, and pathology of brain, cord, and nerves. Competition among medical graduates of not more than two years' standing. Fee £2.

Third Examination in Medicine.—Two first-class exhibitions of £30 each, and two second of £20 each.

Medical Degrees Examination.—Two first-class exhibitions of £40 each, and two second of £25 each. One travelling medical scholarship of £100. One medical studentship of £200 per annum, tenable for two years.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.

The examinations held conjointly by the two Colleges are the inlet of most Irish students to the profession, especially of those educated in Dublin. The course, as in other bodies, extends over five years, with examinations at the end of the first, second, third, and final years. These examinations are conducted by examiners chosen by each of the Colleges for the subjects appropriate to them. The curriculum has recently been revised, and many of the courses have been modified. A number of the examinations are common with the English Colleges, the subjects of the First Professional examination may be studied either at a medical school or at an institution other than a medical school recognised by the Colleges, after due inspection, for instruction in these subjects. We recommend students to apply for the official programme to the Secretary of the Committee of Management, Royal College of Physicians, or to the Registrar of either College. In the case of the Preliminary Examination seven clear days' notice must be given to the Secretary; fourteen days' notice are required from candidates for the Professional examination.

The total of the examination fees, spread over the four examinations, is £42, while the school and hospital fees, if taken in Dublin, amount to £24 19s., making altogether £156 19s., exclusive of re-examination fees, which have to be paid in case the candidate fails to pass his examination.

The conjoint Colleges also confer a diploma in Public Health, of which information will be found on page 304.

ROYAL COLLEGE OF PHYSICIANS IN IRELAND.

This College issues a licence in Medicine and a licence in Midwifery to registered medical practitioners.

The subjects of examination for the former qualifications are:—Practice of medicine, clinical medicine, pathology, medical jurisprudence, midwifery, hygiene, and therapeutics.

The candidate for the licence in Midwifery must produce certificates of having attended a course of lectures on midwifery, and of having attended practical midwifery and diseases of women for six months, at a lying-in hospital or maternity recognised by the College; or, where such hospital attendance cannot have been obtained during any period of the candidate's study, of having been engaged in practical midwifery under the supervision of a registered practitioner holding a public medical appointment, the certificate in either case to state that at least twenty labour cases have been actually attended. A registered medical practitioner of five years' standing is exempted from the examination by printed questions.

Fees.—Fee for the licence to practise medicine, £15 15s. Fee for examination for the licence to practise midwifery, £4 3s.

Membership.—The Examinations for Membership are held in January, April, July, and October.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

This College grants a licence in Surgery to registered medical practitioners. Candidates who hold registrable surgical diplomas, including the licence of the Apothec-
caries' Society of London, granted since October, 1886, are admitted to examination without further evidence of study, but candidates who hold medical qualifications on the L.S.A. granted before October, 1886, will be required to produce certificates of two courses of lectures in anatomy and dissections, one course of practical histology, one course of lectures in surgery, and one course of operative surgery.

Candidates are examined in surgery, clinical and operative; surgical appliances; and opthalmic surgery. The fee is £20 5s. The fee for a special examination is £3 10s. The diploma in Midwifery is also granted after examination to registered medical practitioners. Candidates must produce evidence of (a) attendance on a course of lectures on midwifery and diseases of women and children in a recognized school; (b) attendance on six months' practice at a recognized lying-in hospital or recognized dispensary for lying-in women and children; and (c) of having conducted at least thirty labour cases.

The fee for the examination is £15 15s.

Fellowship.—Candidates for the Fellowship of the College must enter their names with the Registrar at least a month before the date of examination, in order that the Council may decide whether to approve of the examination. Examinations are held the third Monday in February, May, and November. If the application is approved, the candidate will be admitted to the next sessional examination or to a special examination if granted by the Council. Candidates are divided into two grades:

Grade 1.—Licentiates or graduates in surgery of less than ten years' standing.

Grade 2.—Licentiates or graduates in surgery of more than ten years' standing.

Candidates in Grade 1 must pass two examinations—Primary (in anatomy and physiology) and Final (in surgery). Candidates in Grade 2 need pass but one examination in surgery.

Fees.—Grade 1.—For Licentiates of College; Primary examination, £15 15s.; Final examination, £10 10s. Licentiates in Surgery of other licensing bodies: Primary examination, £26 5s.; Final examination, £15 15s. Students of the College: Primary examination, £5 5s.; Final examination, £21. Students of other licensing bodies: Primary examination, £10 10s.; Final examination, £3 10s.

2. Licentiates of the College, £26 5s.

Licentiates in Surgery of other licensing bodies, £42.

APOTHECARIANS' HALL OF IRELAND (L.A.H.).

This body is authorized to grant a complete qualification in medicine, surgery, and midwifery, recognised and admitted under the Medical Act of 1886, entitling the holder to occupy medical appointments in all the public services. It also confers the legal right to dispense medicines in Ireland. The examinations are held on the third Monday in January, April, July, and October, and the requirements in respect of studies are approximately the same as those of the Joint Conjoint Examinations of the Royal Colleges of Physicians and Surgeons in Ireland. The examination fees payable for the qualifications of L.A.H. are as follows:—First professional, £5 5s.; second, £5 5s.; third, £5 5s.; Final examination, £6 6s.

The fees for re-examination are £1 1s. for each subject, excepting in the subjects of chemistry and ophthalmology, the fees for which are £2 2s.

The fee for final alone is £15 15s., when the other examinations have been taken elsewhere. Candidates may be admitted to a special examination under special circumstances at a fee of ten guineas.

Each candidate must produce evidence of having before entering on medical studies passed a preliminary examination in general education recognised by the General Medical Council, and of having been registered by that Council as a student in medicine. Certificates of medical study will not be recognised if the commencement of the course to which the certificate refers dates more than fifteen days prior to such registration, except the subjects of physics or biology. Registration is not undertaken by the Hall, but the student must apply to the Registrar of the General Medical Council that he may be so entered. The details of the course of education required and syllabus of the examinations will be supplied on application to the Registrar at 40 Mary Street, Dublin.

Candidates already on the "Register" will receive the diploma of the Hall on passing an examination in medicine, surgery, midwifery, and pharmacy, and paying a fee of ten guineas. If medicine or surgery are required, two guineas extra will be charged. The candidate will be exempt from each of the above subjects, which are covered by his previous qualification or qualifications.

In addition to the qualifying diplomas awarded by the above bodies there are diplomas in special subjects awarded as well. These are the licence in Dentistry and the diploma in Public Health.

LICENCE IN DENTAL SURGERY.

There is probably no specialty in surgery which gives as great a number of its practitioners a living and the prospect of an income as dentistry. A young man who has got his diploma and knows something of his business, and is willing to attend to it, seldom fails to get a substantial foothold in Ireland in a few years. The Irish L.D.S. is granted by the Royal College of Surgeons.

Course of Study for the Licence in Dentistry.—Candidates are required to pass three examinations viz.:

1. Preliminary (in General Education), Primary Dental, and Final Dental.

The Primary Dental examination is in (1) Physics, (2) Chemistry, including metallurgy, (3) Anatomy, (4) Physiology and histology, (5) Surgery—all these subjects with special reference to dentistry. The examination fee is £10 10s. The Final examination is in (1) Dental surgery—thoretical clinical, and operative; (2) Mechanical mechanics—thoretical and practical, including metallurgy. The fee for this examination is, for a Licentiate of the College, or Students who have passed the Primary Dental or third Professional, £10 10s.; for any other candidate, £26 5s. Each of these examinations must be preceded by complete courses of study in these subjects.

Exemptions.—Candidates educated in England or Scotland are admitted to the examination on the production of the certificates that would be necessary for both Primary and Final examinations in their own countries. Furthermore, the College may admit to examination, sine curriculo, candidates whose names are on the "Dental Register," and who are unable to furnish certificates required by the foregoing resolution, on presentation of a special schedule of application, accompanied by such certificates they may have of general or professional education, and pay the required fee.

THE DIPLOMA IN PUBLIC HEALTH.

This diploma is granted by Dublin University, the Royal University, and the joint Royal Colleges. Every candidate must be a registered medical practitioner. The examination is in:—(1) Chemistry (including chemical physics). (2) Engineering and architecture. (3) Sanitary law and vital statistics. (4) Hygiene. (5) Bacteriology. (6) Meteorology. The General Medical Council recommends that all candidates shall have studied in a special bacteriological laboratory also for six months as pupil of a working medical officer of health, described, for example, as "the medical officer of health of a county or of one or more sanitary districts having a population of not less than 30,000; or a medical officer of health who is a teacher in Public Health of a recognised medical school, and practical in addition to the prescribed course a candidate for the Diploma of the University of Dublin must be a Doctor in Medicine or a graduate in Medicine, Surgery, and Midwifery of Dublin, Oxford, or Cambridge, and his name must be on the "Medical Register" for at least twelve months before the examination. The Royal University only confers its diploma on its own graduates.

THE IRISH MEDICAL SCHOOLS.

The Irish Medical Schools are as follows:—

The School of Physic of Dublin University —
SEPT. 16, 1901.

IRELAND—EDUCATION.

THE MEDICAL PRESS. 313

This school is formed by an amalgamation of the School of Trinity College and of the College of Physicians. Only the medical students are matriculated under the Senior Lecturer, for which a fee of £5 is payable, but he need not attend any of the Arts course unless he desires to obtain a University licence or degree in medicine, and midwifery. No student is permitted to matriculate unless he has passed the entrance examinations of the University, of the Royal University, of the College of Surgeons, or some other examination recognized by the General Medical Council.

The medical scholarships are given annually at the School of Physic, value £40 per annum, tenable for two years, the examinations for which are held each year in June; one scholarship is given in anatomy and in surgery; the others in zoology, chemistry, botany, and experimental physics.

A prize of £100 is awarded by the Board to the successful candidate at a special examination in alternate years in medicine or in surgery, provided that the merit be deemed sufficient. The successful candidate is required to spend three months in the study of medicine or surgery, as the case may be, in Berlin, Paris, or Vienna. Before he can obtain the first instalment of £50 by the Senior Lecturer that be possesses sufficient knowledge of a Continental language to derive full benefit from the prize. The examination is held in June, and is open to students who have passed the Final in Medicine or Surgery, the case may be, within two years of the examination.

In order to obtain the second sum of £50 the prize must have furnished to the Regius Professor his formal report on the hospitals attended by him within two years from the time of obtaining the prize.

Class prizes are given at the end of the session of between £5 and £10 in value.

The John Mallet Purser Medal, founded by Prof. Purser, is awarded annually to the student who, at the ordinary June "Half M.B." Examination in Anatomy and Institutes of Medicine, shall obtain highest marks in Physiology and Histology, provided that he passes the examination in full.

THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

SCHOOLS OF SURGERY.—By the amalgamation of the Carmichael College and the Ledwich School with the School of the Royal College of Surgeons, the combined schools form one of the largest medical teaching bodies in Ireland. These schools are attached by Charter to the Royal College of Surgeons. They are carried on within the College building, and are specially subject to the control of the Council, who are empowered to appoint and remove the Professors, and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the dissecting room nearly tripled, and special histological, bacteriological, public health, and pharmaceutical laboratories fitted with the most approved appliances in order that students may have the advantage of the most modern methods of instruction.

The diplomas of the College are open to students of either sex. Separate rooms have been provided, and careful provision made for the instruction and comfort of women students.

PRIZES.—The Barker Prize, £21; the Carmichael Scholarship, £15; the Mayne Scholarship, £15. The Gold and Silver Medals in Surgery and the Stoney Memorial Gold Medal in Anatomy.

Class Prizes of £2 and £1, are awarded by medals if sufficient merit is shown, will also be given in each subject. Prospectus and Student's Guide can be obtained on written application to the Registrar, Royal College of Surgeons, Dublin.

CATHOLIC UNIVERSITY SCHOOL is situated in Cecilia Street, Dame Street. It prepares students for all medical examinations, particularly those of the Irish Colleges of Physicians and Surgeons, and the University of Ireland. The school has recently been rebuilt and refitted, its working space having thereby been nearly doubled, and several new laboratories, including those for the study of bacteriology and public health, have been added. The institution has also been recently chartered, under the Educational Endowment (Ireland) Act, and it is now controlled by a Board of Governors. The total fees for school and hospital courses is £160, payable as the courses are taken out.

The following Exhibitions are awarded annually:—Two first year's, value £12 10s. each; two second year's, value £10 each; one third year's Royal Exhibition of £10; one final Conjoint Colleges' Exhibition of £12 10s.; two large gold medals, besides several other class medals.

A Guide for Medical Students, which gives all the information required by parents, and by students who desire to join the medical profession, may be obtained free on application to the Registrar.

THE QUEEN'S COLLEGES—BELFAST, CORK, AND GALWAY.

These three important academic institutions were the special schools of the Queen's University. They have ceased to have any direct relation to a central examining body, but educate students for all colleges and degrees, and are maintained, as hitherto, by a handsome Government grant. The same curriculum as that formerly adopted is continued, and the various exhibitions and scholarships are still available. Each college has the disposal of about £1,500 per annum in scholarships and prizes. The curriculum is generally well adapted for preparation for the Royal University examination. It is adapted for higher technical education, having lecture rooms provided with every appliance necessary in the modern training of a medical student. The colleges are completely equipped with students' reading rooms and lending libraries and refreshment rooms, and with all adjuncts to collegiate life, such as literary societies and athletic organisations. The expense of living in the collegiate towns is quite moderate. The course of lectures for the winter session must be diligently attended, as students are not registering a certificate who has not put in three-fourths of a course. The scholarship examinations are held in October.

QUEEN'S COLLEGE, BELFAST.

The total cost of the medical curriculum of the Royal University of Ireland, including examination fees and perpetual fee for the Royal Hospital, but not including fees for the special hospitals, is about £95. If the Conjoint Examination of the Royal Colleges is taken the expense is almost the same.

Clinical instruction is given at the Royal Victoria Hospital, The Maternity Hospital, the Ulster Hospital for Women and Children, the Hospital for Sick Children, the Ophthalmic Hospital, the Ulster Eye, Ear, and Throat Hospital, and the District Lunatic Asylums are also open to students.

PRIZES.—(1) Ten medical scholarships each year, value £20 each; (2) two Dunville studentships (one each alternate year), value £145 each; (3) one Andrews studentship each alternate year, value £145; (4) numerous sessional prizes.

During the summer session special classes are formed in bacteriology and clinical pathology, and during the winter facilities are afforded to medical men to work at these subjects in the pathologist laboratories. From time to time lectures and demonstrations are given in the anatomical department on the Advanced Anatomy of the Nervous System, or some other department of applied anatomy.

A pamphlet containing full information can be had on application to the Registrar, Queen's College, Belfast.

QUEEN'S COLLEGE, CORK.

The arrangements in the Faculty of Medicine are made chiefly with reference to the requirements of the Royal University of Ireland, but students proceeding for the examinations of the Conjoint Boards of England, Scotland, or Ireland, the Society of Apothecaries of London, or the Apothecaries Hall of Ireland, can arrange the course of lectures which they attend, and the order in which they attend them, to meet the requirements of those bodies. Certificates of attendance in the college are also accepted by the University of Cambridge. The total fees for the college lectures and
Hospital attendances required by the Royal University of Ireland is about £85.

Clinical instruction is given at the North and South Infirmary. Students can also attend the Mercy Hospital, Cork Union Hospital, the Cork Lying-in Hospital, the Maternity, the Hospital for Diseases of Women and Children, the Fever Hospital, the Ophthalmic and Aural Hospital, and the Eglington Lunatic Asylum. The winter session commences on October 27th, and ends at the end of May. Courses of the summer session are delivered in the months of April, May, and June.

Scholarships and Prizes.—Eight medical scholarships, two gold medals, the value of £15 each, and in the fifth year the Blaney Scholarship of the value of £35, and a Senior Exhibition, value £30. Three Exhibitions, one in practical medicine, one in practical surgery, and one in practical midwifery, each of the value of £15. Book prizes at the sessional examinations.

Further information can be obtained in the College Regulations, or on application to the Registrar, Queen's College, Cork.

QUEEN'S COLLEGE, GALWAY.
Clinical teaching is carried on in the Galway Hospital, established as a Public General Hospital (in the place of the County Infirmary) by Act of Parliament (1837). The Galway Fever Hospital is also open to students. The medical lectures are recognised by the Royal University of Ireland and the various Licensing Bodies in the United Kingdom.

There are eight Junior Scholarships in Medicine of the annual value of £25 each. Two are tenable by matriculated students of the first, second, third, and fourth years. The Council has power to award exhibitions for distinguished answering. Sessional prizes are offered in each subject. A Senior Scholarship in Anatomy, value £40, the holder of which is usually appointed Demonstrator, is offered annually for competition, tenable for a student by a student who shall have attended the Medical School of the College for at least two sessions, and shall have obtained a Degree in Arts or Medicine, or a Diploma in Medicine, from a Licensing Body. Scholarship examinations are held at the commencement, and those for Sessional Prizes at the close of each session.

THE PHARMACEUTICAL SOCIETY OF IRELAND.
The Pharmaceutical Society of Ireland issue two qualifications and a certificate. The qualification of Registered Tassistant: the qualification of Pharmaceutical Chemist; and the certificate of competency as Assistant to a Pharmaceutical Chemist.

Registered Druggist.—This qualification entitles the holder to open shops for the selling, retailing, and mixing of poisons. In order to obtain it, a person must have served an apprenticeship or assistantship of four years to an apothecary, pharmaceutical chemist, or to a person who was, or would have been entitled to become, a registered chemist and druggist or a registered druggist. He shall be examined with respect to his knowledge of English orthography and composition, arithmetic, and the weights and measures of the British Pharmacopoeia, the appearance and properties of the various drugs and chemicals in general use, and as to the provisions of the Poisons Act. The fee is four guineas—two for examination and two on registration.

Examinations in Dublin (also in Belfast and Cork or other place if 12 candidates offer) on the second Tuesday of January, April, July, and October.

Pharmaceutical Chemist.—The qualification of a pharmaceutical chemist in Ireland confers greater privileges than is the case in England.

The subjects of examination are divided between the "Preliminary" and the "Licence."

The Preliminary examination is held on the first Tuesday and following days of January, April, July, and October.

The fee is £2 2s. for the first attempt, and 10s. 6d. for each subsequent examination. Further particulars with reference to the subjects for examination may be obtained from the Registrar. The British Society's examination is accepted in lieu of this, as well as those recognised by the General Medical Council as a preliminary to medical studies.

Pharmaceutical Chemist and Licentiate Examination.—This examination confers the title of Pharmaceutical Chemist and the right to compound medical prescriptions. Candidates must be 21 years of age, and must have passed the Preliminary at least a year previously. They must, unless they have passed the Preliminary previous to 1884, produce certificates of having served four years as assistant or apprentice to an apothecary or dispensing chemist and four years to a druggist, also a certificate of having attended a course of practical chemistry of not less than three months' duration, and of having actually worked at the bench for 100 hours during the said course at a recognised school. The fee for examination is five guineas, and for re-examination a guinea and a half. Examinations will be held in Dublin on the second Wednesday and following days of January, April, July and October.

Assistant to a Pharmaceutical Chemist.—The examination for the certificate of competency as an assistant may be described, in brief, as the same as that for the Licence, minus the examination in chemistry and botany, with the fee reduced to one guinea (half a guinea on the second and subsequent attempts). The Preliminary examination must be passed as for the Licence, and the usual 14 days' notice must be given. Candidates must have been engaged in practical pharmacy for four years.

Examinations will be held on the second Mondays of January, April, July, and October, or on such days as the Council may direct.

DEPARTMENT OF AGRICULTURE AND TECHNICAL INSTRUCTION FOR IRELAND.
ROYAL COLLEGE OF SCIENCE FOR IRELAND.
SESSION 1902-1903.

This College, situate in Stephens Green, Dublin, supplies a complete course of instruction in science applicable to the industrial arts, especially those which may be cast broadly under the heads of chemical manufactures, engineering, physics, and natural science. A diploma of Associate of the College is granted at the end of the three years' course. Non-associate students may join for any course required. There are four Royal scholarships of the value of £30 each yearly, with free education, tenable for two years. Two are competed for by the associate students at the end of each session. The Chemical, physical, meteorological, and botanical, geological and mineralogical laboratories and drawing schools are open daily for practical instruction. The Session commences on Thursday, October 1st.

The courses of chemical, physical, and geological, and mineralogy and zoology are recognised by the Royal University of Ireland, and certificates of attendance are granted to medical and other students attending these courses, as also the courses of the chemical, physical, zoological, botanical, and geological laboratories.

THE DUBLIN HOSPITALS.
The clinical hospitals in Dublin are ten in number, exclusive of three lying-in hospitals. There are also two children's hospitals, an orthopaedic hospital, a fever hospital, an ophthalmic hospital with two centres, a dental hospital, and other special institutions. Some of the clinical hospitals, though they have no actual or official connection with any school, are in close affinity with certain teaching bodies; while others, again, are without any special connection with any school. While, however, such affiliation of a school or hospital may exist, it should be remembered that the Dublin schools and hospitals are open to all comers, and the student is competent to attend any hospital or any school he wishes, and to change his place of instruction from year to year as he may see fit.

The Irish Licensing Bodies require attendance on hospitals for twenty-seven months, i.e., three winter sessions of six months and three summers of three
months, with the five years of study. The fee at all general hospitals is £6 6s. in winter, and for the summer £6 12s. for the entire session of nine months if taken together.

GENERAL HOSPITALS.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.—The accommodation at these hospitals is as follows:—Hardwicke Hospital, 120 beds; Whitworth Hospital, 82 beds; Richmond Hospital, 110 beds; total, 312 beds. The hospitals are visited each morning at nine o'clock by the physicians and surgeons, and, in addition to the usual bedside instruction, clinical lectures are delivered on the most important cases. In addition to the above, very special branches of medicine and surgery. The Truss Establishment, for the distribution of trusses to the ruptured poor of Ireland, is connected with these hospitals. There are very large opthalmic, auric, throat, and gynaecological dispensaries, and instruction in these important subjects is given. Eight resident clinical clerks are appointed each half-year, and provided with furnished apartments, fuel, &c. The appointments are open only not only to clinical clerks, but also to those who are qualified in medicine or surgery. A house surgeon for the Richmond Hospital and a house physician for the Whitworth and Hardwicke Hospitals are employed, annually, and receive a salary. The Richmond Lunatic Asylum, containing 1,000 beds, adjoin these hospitals.

METH HOSPITAL AND CO. DUBLIN INFIRMARY.—This hospital was founded in 1753, and now contains 160 beds available for clinical teaching. A new building for the isolated treatment of fevers, containing 40 beds, has recently been added. The certificates of this hospital are recognised by all the Universities and licensing bodies of the United Kingdom. Medical and surgical resident pupils and clinical clerks and dressers are appointed every six months, and a house surgeon is elected annually. A prospectus giving the complete arrangements for medical and surgical classes for the coming session may be obtained from the Secretary of the Medical Board, Mr. Lane Joynt, F.R.C.S.I., 84 Harcourt Street, Dublin.

THE ADELAIDE MEDICAL AND SURGICAL HOSPITALS are in Peter Street, and occupy a central position within a few minutes’ walk of the College of Surgeons and Trinity College. From October 1st, the physicians and surgeons visit the wards and give instruction at the bedside. There is a large teaching fever hospital, and also wards for infants and children. Operations are performed, except in cases of urgency, at 10 a.m. on Tuesday, Thursday, and Saturday. Special hours are devoted to clinical instruction in the diseases of women, and students are individually instructed in the use of the stethoscope, ophthalmoscope, laryngoscope, and microscope; also special instruction is given on practical pathology and X-ray photography. Three resident pupils are selected half-yearly and a house surgeon annually. Prize examinations, including examinations for the Hudson Scholarship, £50 and a gold medal, and a senior prize of £10 and a silver medal, are held at the termination of the session. The large dispensaries afford facilities for the study of eye, ear, throat, and cutaneous diseases, as well as of minor surgery and dentistry. Further particulars from Mr. Huxton, F.R.C.S.I., 12 Stephens Green North.

THE ROYAL CITY OF DUBLIN HOSPITAL.—This hospital is situated in Upper Baggot Street, about ten minutes’ walk from the Royal College of Surgeons and Trinity College. It has just been enlarged and improved, and has a very considerable number of specialty instruction. It is also a separate building for infectious diseases, Clinical clerks to the physicians and dressers to the surgeons are appointed from the most deserving of the class. A new operation theatre, sterilising room, and anesthetist room have been constructed in accordance with the most modern surgical requirements. A Röntgen-ray and light treatment of lupus department has recently been added. A resident medical officer is elected annually, and resident medical and surgical pupils are appointed from among the most deserving students of the hospital. Operations are performed on Tuesdays, Thursdays, and Saturdays, at 10 a.m. Full particulars can be had on application to Mr. Jameson Johnston, M.B., F.R.C.S.I., Hon. Sec. Med. Board.

SIR PATRICK DUN’S HOSPITAL is situated on the south-eastern side of the city, and about half a mile from the University School of Physic. It is officered prescribably by the members of the medical school. Formerly all University students were compelled to attend this hospital, which was purely a medical institution, but some years ago the obligation was removed, and the hospital was opened for surgical cases. It is now free to all students. There is a special wing devoted to fever cases, and regular clinical instruction is given by the members of the medical staff throughout the winter and summer sessions. Special classes for students commencing their hospital studies will be held in these departments during the months of October, November, and December. They will embrace the elements of medical and surgery, including note-taking. Opportunities are also given to students for examining cases of throat, ear, and eye diseases, as well as for performing minor surgical operations and bandaging. In the X-ray Department there are opportunities for examining cases of accident and examination of X-rays to the diagnosis and treatment of injury and disease.

MATER MISERICORDIAE HOSPITAL.—This hospital, containing 155 beds, is open at all hours for the reception of accident and urgent cases. Fifty beds are specially reserved for the reception of patients suffering from fever and other contagious diseases. A course of lectures and instruction on the diseases of fever will be given during the winter and summer sessions. A certificate of attendance upon this course to meet the requirements of the various licensing bodies may be obtained. Opportunities are afforded for the study of the diseases of women in the wards under the care of the obstetric physician, and at the dispensary, held on Tuesdays and Saturdays. Lectures on clinical gynaecology will be delivered on Saturdays at 11 a.m. Ophthalmic surgery can be taught in the special wards and special course of instruction in pathology and bacteriology, as applied to medicine, will be given. Connected with the hospital are extensive dispensaries, which afford valuable opportunities for the study of medical and surgical diseases, accidents, &c. Leonard Prizes: One gold and one silver medal will be offered for competition annually in the subject of medicine, and one gold and one silver medal in the subject of surgery. Junior Leonard Prizes: Two prizes of the value of £3 and two prizes of the value of £2 will be offered for competition in medicine and surgery respectively.

MERCEY’S HOSPITAL.—This hospital, founded in 1707, is situated in the centre of Dublin, in the immediate vicinity of the Schools of Surgery of the Royal College of Surgeons, the Catholic University School of Medicine, and within fifteen minutes’ walk of Trinity College. It contains 130 beds for medical and surgical cases, and arrangements have been made with the medical officers of Cork Street Fever Hospital whereby all students of this hospital are entitled to attend the clinical instruction of that hospital and are eligible for the posts of resident pupil, &c. There is a large out-patient department, and a special department for diseases peculiar to women. There are also special wards for the treatment of consumption and lumbago’s diseases. During the past few years the hospital has undergone extensive alterations in order to bring it up to modern requirements. A house surgeon is appointed annually. The resident pupils are appointed, each for six months, and clinical clerks and dressers are appointed from among the most deserving members of the class. The certificates of this hospital are recognised by all the licensing bodies. For further particulars apply to
Mr. R. Charles B. Maunsell, M.B., F.R.C.S., 32 Lower Baggot Street, Dublin.
